Smart Operations Of Smart Grids Integrated With Fuel Cell With Controlling Strategies

Rakesh Sahu, Y. Bhanu Sandhya, Srikant Mishra, K C Rath

Abstract: This paper provides the management methods of AC & DC smart grids. AC smart grids square measure a convenient approach to integration distributed energy systems with utility power systems. Smart grid may be a arrangement of smart generators, fuel cell, storage systems and masses. DC micro grids will cause additional economical integration of distributed generation. The methods of smart grids measure completely by the management of converters.

In solar panel maximum cost utilized in storage systems like battery. In this paper a latest method has been recommended to replace the battery with fuel cell. Stored hydrogen used as a fuel which generate electricity. In this type of hydrogen storage system efficiency is not more than 55 percentages. This paper explaining about the scheme of the management methods of converter and the management methods of smart grids in each AC & DC conditions.

Keywords: Solar photo voltaic, Electrolyze, Battery bank, energy cell, Hydrogen Storage cell, smart grid, control of smart grid.

I. INTRODUCTION

Through the progressively grim issues of fossil energy depletion and ecological pollution, exploit the clean energy like renewable resources became more importance. Renewable energy sources contribute to the quicker development of distributed generators. Generation is nothing moreover the Combined effect of Heat and Power (HP) which might be outlined because the next generation of different style of energy with one most important energy supply, largely energy and thermal energy. However, inflated infiltration of distributed energy resources into typical power systems will increase management challenge. As a result, the construct of smart grid is proposed. Energy won’t to drive associate degree generator for manufacturing electricity and rotating instrumentation like machine, pump, compressor and fan for delivering alternative services. Smart grid combines smart generators, fuel cell, energy storing systems and hundreds along and works as a resourceful and controllable unit. Smart grid will work each on grid-connected and isolated condition which might raise the responsibility of grid effectively. Due to uncertainty of smart generators and also the low level of power capability of smart grid system, dominant of smart grids has become a good issue. Plenty of analysis has been created on management ways each of ancient AC smart grid and DC smart grid. There are two methods for utilizing the thermal energy one is direct method and another is indirect method in which hot water into steam and hot air for appliance or chilled water for cooling. Generally smart grids are different types and they are AC smart grid, DC smart grid and mixing of smart grid i.e. known as hybrid smart grid. Hybrid smart grid is seen as a mix of AC smart grid and DC smart grid and fuel cell, renewable energy sources. The management of smart grid primarily includes the management of physical level and also the management of grid level. The management of physical stage consists of the management of smart generators, energy storage systems and fuel cells. It’s complement primarily through the management of various types of inverters. The management of grid level is seen because the combination of the management methods of various types’ of generators and energy stored systems.

II. COMBINED HEAT AND POWER TECHNOLOGY

Combined heat & power will be a range of financial advantages for the large users of energy. The high potency of Combined Heat Power tools may result savings in energy when put next to standard, severally purchased power and onsite thermal energy systems. to see if it is probably going to help a compelling come on investment at a selected website, the prices of the HP system ought to be compared to the investment of purchased power and thermal energy (hot water, steam water) that may preferably be needed for the locality. Chillers or boilers in heat & power (HP) may be put in new construction projects or once major heating, ventilation, and air con instrumentation must get replaced or modernized. The traditional method of cooling and heating method cause an enormous environmental pollution, which might get replaced by the technology of gift era that is cogeneration and triple-generation. By this technology the wasted heat once more may reutilized for the aim of plight system and by introducing small cooling system. This cooling system can be increases the quality of air by reducing emissions of air pollutants and greenhouse gases. A SO2 particular includes the most significant regulated pollution.

III. FUEL CELL SYSTEM

The technology shows potential for fuel cells area unit to serve thermal and power wants with terribly low emissions and with high strength. Fuel cells use a chemical energy or set of battery like method to convert the energy of H into water and electricity. Chemical element react to supply water within the presence of a solution and, in doing therefore, generating & chemical science potential that driven a current through an external circuit. Additionally the reaction will dissipate heat. From the fossil fuel H can be obtained which is useful for cell. As a result of gas happens naturally solely in fossil fuel. There are four differing types of fuel cells that are used for stationary mutual power and heat applications. That proxy acid, liquid carbonate, solid chemical compound and nucleon exchange membrane. Extra electric cell sorts that are direct wood alcohol and alkaline used as mainly in shipping and non motionless electric cell applications. The solution and operational temperatures vary for every of the electric cell sorts. The operational temperatures vary from close to close to 1800°F and electrical generating efficiencies vary from thirty p.c to around fifty p.c on a spread of Higher Heating worth basis.

IV. GOAL OF GREEN BUILDING TECHNOLOGY

Green structure includes a structure, which is planned, fabricated, worked, kept up or reused with destinations to ensure inhabitant’s wellbeing, improves the representative profitability, utilize shrewdly common assets and diminish the natural effect. Green structure which is otherwise called green technology development or tolerable structure grows and supplements the structure design uncertainties of economy, effectiveness, durability, and support. A Green Building where less water used which enhance strength of productivity, monitors characteristic resources, creates less waste materials and gives more advantageous space to worker when contrasted with ordinary structures. The goal of the green structures is to create structures which use the common assets to the negligible at the time of development and operational stage. Green structures stress on the asset use productivity and furthermore depending upon the three words – Reuse, Reduce and Recycle. Green Building is collaboration and the structuring and development incorporates specialists from structures, finishing, air molding, pipes, vitality and electrical field. These specialists evaluate the effect of the every single structure on the ecological condition, keeping in cerebrum the capital included. The last structure should be practicable and ought to limit the unconstructive effects that the structure would have on the earth.

V. CONTROL SCHEME OF GRIDS

All the methods carry with its management methods of converters and grids. we have a tendency to all understand that each one micro terminals square measure connected to bus through totally different sorts of converters. Management of converters can be accomplished by managing the smart terminals. Methods for managing the smart grids are the combination of some management of converters. The challenges are seen from management methods are depending upon quality and result of management. Some management methods will resolves drawbacks of smart grid power flow, calculates optimum references for the smart grid sources mostly based on financial objectives by adding alternative layers and additional complicated communication system. It’s vital for US to learn the benefits and downsides of various management methods to seek out a balance.

VI. VF CONTROL OF AC MICRO GRID

Control of VF means that to stay the voltage and frequency to a constant and stable to different elements within the smart grid. The smart terminal below VF management must to react to the ability change in smart grid quickly. Usually, VF management is applied within the isolated condition and therefore the capability of this part below VF management ought to be huge enough. Here is that the control theme of VF management, as shown in Figure1. This and potential loop generate the decoupled potential because the compared voltage wave to urge management signal. The frequency loop generates the reference innovate VF management.

VII. IMPORTANCE OF GREEN BUILDING

The development and improvement of our networks largely affects our regular habitat. The assembling, structure, development and task of the structures in which we live and work are in charge of the utilization of a considerable lot of our common assets. Green structure which is shown in figure2 includes a structure, which is planned, fabricated, worked, kept up or reused with destinations to ensure tenant’s wellbeing, improves the worker profitability, utilize carefully common assets and decrease the ecological effect. Green structure which is otherwise called green development or endurable structure grows and supplements the structure configuration worries of effectiveness, robustness, economy and solace. A Green Building where less water used, advances vitality effectiveness, saves regular assets, produces less waste materials and gives more beneficial space to worker when contrasted with ordinary structures. Several benefits we are getting from the green building such as it conserve.
natural resources, reduce CO2, reduce water pollution etc.

**Figure2 Green building**

**VIII. CONVENTIONAL BUILDINGS**

Green building and standard building both are separate as looking from outside, however relating to kind of technology used and boundaries render. The main purposes of inexperienced buildings are to decrease energy and consumption of water, utilization of barren, victimization of materials, etc. In the other way, the design of standard buildings not designed properly looking the view of energy, water supply, materials, indoor temperature and humidity. By combing this reduces the manufacture of waste materials and reusable them. In consequence to normal building, inexperienced buildings are further energy economical, have lower operational and maintenance prices, offer higher pacify and well for occupants, have lesser risk of potential and cut back pessimistic impact on the setting. An inexperienced building might be a construction that represents the leading well-organized and least unquiet approaches of victimization land, use of water and energy possessions whereas making certain the healthful apparent setting for the householder.

**IX. EFFICIENT HEAT REVIVAL FROM FUEL CELL**

Heat can be recouped from power device as boiling the water or little-weight steam (< 32 PSIG); however for nature of warmth was shift, which is relies upon the kind of energy component and its working warmth. The one exemption to this is, a few produces of SOFC do not recoup the warmth for a use in different utilization and rather utilizes the warmth to support the inward procedures which improves electrical age effectiveness.

**X. SIMULATION & RESULTS**

Presently this research paper, to verify the framework effectiveness reenactment was being finished by utilizing HOMER energy tool. The total procedure for the incorporating system could be comprehended from the figure underneath. At this juncture the electrolyzes will obtaining the power from Photo Voltaic framework In order to creating hydrogen to running energy component alongside to meeting both Direct current and Alternating Current loads. This created hydrogen utilized in fuel cell to deliver power. By using this procedure the totally Framework winds up inexhaustible. With this we resolve probably run both Alternating Current and Direct Current loads.

**XI. COST OUTLINE**

From the recreation report we investigated the general expense outline of the framework for example the net present expense, lovelies cost of vitality, working expense of the procedure. As per this following figures, again this graphical portrayal of the net present expense for Photo Voltaic, energy component, converters, electrolyses, hydrogen tank as for capital cost, substitution outlay, working outlay are prepared below.

**XII. CONCLUSION**

In this simulation approach we got the outcome with the purpose of how proficiently we are capable of running the entire framework by sun based set-up and a power device daylight and darkness hours without the assistance of any battery framework. In this way here the cost, running, and substitution of batteries are maintained a strategic distance from. As the issues of batteries are maintained a strategic distance from subsequently the compensation time frame will decrease. The evaluation of recompense period is done and determined to ten to twelve years. So in this report we able to gather that in the event that we will go along these lines we can make a green situation. Presently one more thing is the expense of energy component and sun powered board will diminish soon. At that point absent the attainability of the entire task will be more.

AUTHORS PROFILE

Rakesh Sahu received his M.Tech Degree in Power Electronics & Drives from GIET, Gunupur under BPUT and also B.Tech from BPUT. He is working as Asst. Professor in EEE Department at GIET University. His areas of interest are Control of Photovoltaic Power System, Microgrid and Power Electronics.

Y. Bhanu Sandhya received her M.Tech Degree in Power Engineering from JNTUH and also B.Tech from JNTUH. She is working as Asst. Professor in EE Department at GIET University.

Srikant Misra received his M.Tech Degree in Power Electronics & Drives from GIET, Gunupur under BPUT and also B.Tech from BPUT. He is working as Asst. Professor in EE Department at GIET University.

Dr. K C Rath received his PhD from NIT and M.Tech in Mechanical from GIET, Gunupur under BPUT and also B.Tech from BPUT. He is working as Assoc. Professor in EEE Department at GIET University.
