Abstract
Crown lengthening is a surgical procedure aimed at exposure of a larger tooth surface by gingivectomy alone or with cortical bone remodelling for aesthetic purposes in the anterior zone of the maxilla or for reconstruction of teeth affected by subgingival caries. We report two cases of crown lengthening in the anterior maxilla for aesthetic purposes by gingival and bone re-contouring performed by erbium-doped yttrium aluminium garnet (erbium:YAG) laser. As highlighted in this report, the erbium:YAG laser-assisted crown lengthening is less invasive and also leads to faster clinical outcomes in contrast to the conventional surgical technique by scalpel incision, flap elevation and osteoplastic.

Keywords
flap-less crown lengthening, Erbium:YAG laser; smile line
Introduction
Several clinical situations may require dental crown lengthening (CL) such as irregular smile line, gummy smile, decayed or fractured teeth, worn out teeth by parafunction habits (e.g. bruxism).

Regardless of aesthetic or functional purpose, the conventional technique of CL involves scalpel incision, flap elevation and bone remodeling by burns, with or without adjunctive gingivectomy, the latter essentially related to the gingival biotype.

Despite the excellent clinical outcome, the conventional surgical technique may be more invasive depending on the severity of the clinical situation as well patient’s general health condition (e.g. medically compromised patients or in therapy with anticoagulant drugs). Many alternatives techniques for CL have been reported in literature but it is generally accepted that the least invasive are the laser-assisted techniques.

Of these, the erbium:YAG laser has the advantage to work on both hard (bone) and soft tissues (gingiva).

We report on 2 cases treated by a mini-invasive erbium:YAG laser-assisted procedure (including gingiva and bone re-contouring) for CL in the anterior maxilla.

Cases presentation

Case 1
The patient was a 53 y.o. Caucasian woman with an no relevant medical history who was unemployed at the time of presentation (March, 2015). She presented an abundant gingiva covering tooth 1.2 which she wished to remove for aesthetical purposes (Figure 1a,b). Gingival remodeling and bone re-contouring by erbium:YAG laser was suggested. A small amount of anesthesia was injected locally (0.9 ml of mepivacaine cloridrate 2%, 1:100,000 epinephrine) after which the gingiva was remodeled by laser (Key Laser 3-Kavo s.r.l.) in de-focalized modality (not in contact tip, 180 MJ/10 Hz, poor water emission) until the dental crown was sufficiently exposed according to the patient smile line (Figure 1c,d). After one week (Figure 2a), a second procedure was performed to re-contour the marginal bone by the same laser, using a surgical tip (small scalpel-like tip, 120 MJ/10 Hz, abundant water emission) in contact modality and through the gingival sulcus (flap-less); a light bleeding occurred during the procedure (Figure 2b). The gingival margin was completely healed, and the smile line appeared significantly improved 12 days after surgery (Figure 2c).

Case 2
This 47 y.o. Caucasian housewife who presented in April 2016 with severe abrasion of the anterior teeth related to bruxism over a long duration (Figure 3a). Her medical history was un-remarkable. No pain and/or teeth hyper-sensibility were indicated by the patient, however, she was unhappy with her smile. A laser-assisted CL of the lateral and central incisors was planned to re-define a new marginal gingiva profile. After local injection of anesthesia, (1.8 ml of mepivacaine cloridrate 2%, 1:100,000 epinephrine), the marginal gingiva was carefully recontoured by erbium:YAG laser (Key Laser 3-Kavo s.r.l.) (not in contact tip, 180 MJ/10 Hz, poor water emission) till an adequate teeth exposure (Figure 3b,c); subsequently, the cortical bone was remodeled by a surgical tip (small scalpel-like tip, 160 MJ/10 Hz, abundant water emission) on both aspects of the maxilla through the gingival sulcus without flap elevation (Figure 3d). After 14 days, gingival tissues appeared healed and teeth prepared for the following prosthetic restoration by cemented metal-ceramic crowns. (Figure 3e,f).

Discussion
Several medical devices have been proposed to make CL less invasive, including piezosurgery. Several lasers such as diode,
neodymium-doped yttrium aluminum garnet (Nd:YAG), potassium titanyl phosphate (KTP), CO₂. Erbium, chromium-doped yttrium, scandium, gallium and garnet (Er:Cr:YSGG) and erbium: YAG are widely used for CL. In fact, the main difference between these is their capability to work exclusively on soft or hard or both tissues. Diode, Nd:YAG, KTP and CO₂ lasers may be useful when only gingival remodeling alone is necessary and this is essentially related to their surgical capabilities, especially contextual cuts and coagulation. In fact, they are generally suggested for many surgical and non-surgical procedures in the oral cavity (frenectomy/frenulotomy, vestibuloplasty, mucosal biopsy, treatment of tooth hyper-sensitivity, benign, potentially malignant and malignant lesions removal, surgical and non-surgical periodontal treatments including drug-related gingival overgrowth, photocoagulation of venous malformations, etc.), but not for bone treatments. When both gingival and bone remodeling is required, instead, the choice necessarily must fall on Er:Cr:YSGG or erbium:YAG lasers thanks to their selectivity for water, resulting in the capability to work by ablation on hard tissues as tooth and bone. Therefore, such lasers can be used for dental cavity preparation, periodontal treatments and bone remodeling or cutting. In the reported cases, authors used an erbium:YAG laser both for soft and hard tissue treatment but with different tips and output energy parameters. The excellent clinical outcomes we described in terms of minimal invasiveness, lack of intra- and post-operative complications and pain, fast and predictable healing, are essentially related to the intrinsic proprieties of the erbium:YAG laser light and to the generally recognized gentle laser-oral tissues interaction.

Conclusion

The overall clinical benefits of the erbium:YAG laser allows flapless CL to be simplified, even in difficult cases. The total absence of laser-related thermal injuries to the oral hard and soft tissues leads to highly predictable clinical results, and this is important in the treatment of the anterior teeth for aesthetic purposes. However, a good knowledge of laser-tissue interaction principles, sufficient experience on laser use and, obviously, familiarity with the general and basic guidelines of oral/periodontal surgery are mandatory to achieve desirable clinical results.

Consent

Written informed consent for publication of their clinical details and clinical images was obtained from the patient.

Data availability

Underlying data

All data underlying the results are available as part of the article and no additional source data are required.

- In two cases please add pulse duration of laser device you used for each purpose and laser tip diameter and length.
- You can add some more information about the advantages of erbium lasers.
- It's better to add case report in title of your manuscript.
- This article after minor revision can be acceptable for indexing.

Is the background of the cases' history and progression described in sufficient detail?
Yes

Are enough details provided of any physical examination and diagnostic tests, treatment given and outcomes?
Yes

Is sufficient discussion included of the importance of the findings and their relevance to future understanding of disease processes, diagnosis or treatment?
Yes

Is the conclusion balanced and justified on the basis of the findings?
Yes

Competing Interests: No competing interests were disclosed.

Reviewer Expertise: photodynamic therapy, laser surgery, photobiomodulation, hard tissue
surgery, soft tissue surgery

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard, however I have significant reservations, as outlined above.

Author Response 15 Jan 2021

saverio capodiferro, University of Bari, Bari, Italy

Thank you very much. Changes have been made accordingly.

Dr. Saverio Capodiferro et al.’s article reports two cases of a crown lengthening procedure with an Er:YAG laser. This procedure aims at exposure of a larger tooth surface usually on the anterior maxillary region by gingivectomy alone (soft tissue crown lengthening), or gingivectomy and cortical bone remodeling (hard tissue crown lengthening). The advantages of the Er:YAG method, compared to the classical scalpel one, is that it leads to a predictable outcome and a faster healing. The background of the cases’ history and progression described is in sufficient detail. The authors have introduced us to the patients, their age, history of the disease and the reason why they sought for the crown lengthening procedure in particular. There is enough data provided of the examinations and diagnostic tests, treatment given and outcomes. The authors described in detail what the gingival level was, and illustrated the gingival overgrowth, the steps and the clinical outcome with excellent photos, including a CAD/CAM scan. They also added photos after the procedures and the results after the final restorations. The discussion is sufficient and it accentuates on the importance of the outcome and the better and faster healing of the Er:YAG laser crown lengthening, compared to the classical method with the scalpel. It gives much details on the wide areas of use of the different lasers, as well as a comparison between them – their advantages and disadvantages, as well as their indications and contraindications. The conclusion is balanced and summarizes the findings. One of the most important advantage of the Er:YAG laser method described is the better healing and the predictable results, which is mentioned in the conclusion. My only small recommendations for them, which are not obligatory, are the following: to change ‘a small anesthesia’ to ‘a little bit of anesthesia’ and to describe what type of anesthesia
they used (e.g. terminal, intra-ligamental, etc.); ‘light bleeding’ – should be written without ‘a’; it
would be useful if they could provide the readers with some more information and the precise
specification of the laser, laser mode and scalpel tip used; ‘her medical history was un-remarkable’
is a statement that I could not quite understand, maybe the readers need some more clarity, as
well.
I congratulate the team with the good work, the efforts and the wonderful outcomes and wish
them to more and more success in the future. The article is interesting and well-described. I will
definitely vote ‘approved’ for this article.
