**ABSTRACT**

**Objective(s):** *Acinetobacter pittii* has become an emerging opportunistic nosocomial pathogen worldwide with multi-drug resistance. In the present study, an *A. pittii* strain was isolated from bronchoalveolar lavage fluid sample harboring both OXA-58 and NDM-1 carbapenemase producing genes. The mechanisms of carbapenem resistance of the *A. pittii* strain was investigated.

**Materials and Methods:** Carbapenemase producing genes were examined by PCR and DNA sequencing. S1-PFGE was used to localize carbapenemase encoding genes. Filter mating and electrotansformation were used to investigate the transferability of such carbapenemase encoding genes between different strains. Genetic surroundings of *bla*OXA-58 and *bla*NDM-1 genes were detected as well.

**Results:** The *A. pittii* strain, carrying both OXA-58 and NDM-1 carbapenemase encoding genes, was resistant to all β-lactam antibiotics, while susceptible to ciprofloxacin, levofloxacin, tobramycin, cotrimoxazole and tigecycline. Southern blot hybridization for the *bla*OXA-58 and *bla*NDM-1 gene indicated that the two genes locate in the same plasmid with molecular weight of 310.1-336.5kb. *BlaoxA58* was located in an ISAba3-blaoxA58-ISAba3-like structure, and the blaNDM-1 gene cluster was embedded in an ISAba125-aphA6-blaoxA58-dtrA6-dsbC-cutA5 structure sequentially.

**Conclusion:** In the present study, it is first reported an *A. pittii* clinical strain in China, co-harboring OXA-58 and NDM-1 carbapenemase producing genes residing on a same plasmid. In hospital and community settings, it is of great significance and urgency to increase the surveillance of these kinds of organisms.

---

**Introduction**

*Acinetobacter spp.* are frequent pathogens responsible for nosocomial infections, including *Acinetobacter baumannii* as the predominant species followed by *Acinetobacter pittii* and *Acinetobacter nosocomialis* (1). Since the phenomenon of carbapenem resistance increasingly emerges, there is a big challenge of multidrug resistant *Acinetobacter* in treating hospital infections (2, 3).

To our knowledge, the increasing expression of OXA type carbapenemase genes is the most frequent mechanism of carbapenem resistance in *Acinetobacter*. It mainly includes the intrinsic *bla*OXA-51-like gene as well as the horizontally acquired genes such as *bla*OXA-23-like, *bla*OXA-24-like and *bla*OXA-58-like genes (4, 5). The *bla*OXA-23-like genes are much more prevalent than the *bla*OXA-24-like and *bla*OXA-58-like genes. All of them are capable of yielding carbapenem resistance in a high level and result in serious local outbreaks (6-8). Moreover, the expression of metallo-β-lactamase (MBL) carbapenemase also plays an important role in carbapenem resistance of *Acinetobacter*, including IMP, VIM, SIM, and NDM detected previously in *Acinetobacter* (9). Although these MBLs genes were less detected than OXAs, their carbapenemase activities were typically much higher (10, 11). Especially, since 2008, there have been an increasing number of reports about the dissemination of NDM-1-producing *Acinetobacter spp* in many countries and it resulted in a major threat for clinical treatments in view of its highly frequent co-occurrence with other resistance genes (12-14). Recently, the global spread of *bla*NDM-1-harboring *A. pittii* strains is fierce. With these powerful genes, as the reservoirs for dissemination, they are able to transfer highly across various bacterial species (15-17).

In this study, we investigated the antibiotic susceptibility, genetic environment, and transferability of a single clinical *A. pittii* isolate co-harboring *bla*NDM-1 and *bla*OXA-58 genes on a same plasmid, in order to improve awareness of the urgency of carbapenemase-producing *A. pittii* isolates in China.

**Materials and Methods**

**Bacterial isolates**

The *A. pittii* was isolated from a bronchoalveolar lavage fluid sample of a 56-year-old man suffering from chronic obstructive pulmonary disease (COPD). It was initially identified as *Acinetobacter calcoaceticus baumannii* by Vitek 2 system (bioMérieux, Marcy l’Etoile, France). To confirm the identity of this strain, a fragment of the 16S rRNA gene was amplified using primers 27-forward (5‘- AGA GTT TGA TCC TGG CTC-3‘) and 1513-reverse (5‘- TCT TCA TTT GGT CTA CAA-3‘) and sequenced. The 16S rRNA gene sequence of the *A. pittii* was compared with that of the reference strain of *A. pittii* (ATCC BAA-516). Both sequences were obtained from the GenBank database. The 16S rRNA gene sequence of the *A. pittii* isolate showed 99% identity to the reference strain of *A. pittii* (ATCC BAA-516), indicating that the identity of this strain is *A. pittii*.
Dye Terminator Cycle Sequencing Ready Reaction kit amplicons were sequenced using the ABI PRISM Big 1, VIM-1. These primers are shown in Table 1. All OXA-143, OXA-24, NDM-1, GIM-1, SPM-1, IMP-1, SIM-1 was performed, including OXA-51, OXA-23, OXA-58, OXA-143, OXA-24, NDM-1, SIM-1, VIM-1. These primers are shown in Table 1. All amplicons were sequenced using the ABI PRISM Big Dye Terminator Cycle Sequencing Ready Reaction kit (Applied Biosystems -2- Inc, USA).

Antimicrobial susceptibility testing
The minimum inhibitory concentration (MIC) of various antibiotics was detected on the Vitek 2 system (bioMérieux, Marcy l’Etoile, France).
According to the CLSI clinical breakpoints (2017; CLSI Document M100-S27), antimicrobial susceptibility was interpreted. The following antibiotics were investigated in the present study: amikacin, ciprofloxacin, ampicillin/sulbactam, ceftazidime, imipenem, ceftriaxone, tobramycin, piperacillin/tazobactam, cefepime, gentamicin, levofloxacin, meropenem, rifampin and tigecycline. Quality control for the MIC analysis was carried out with Pseudomonas aeruginosa ATCC 27853 and Escherichia coli ATCC 25922.

Screening of carbapenemases encoding genes
Amplification of carbapenemases encoding genes was performed, including OXA-51, OXA-23, OXA-58, OXA-143, OXA-24, NDM-1, SIM-1, VIM-1. These primers are shown in Table 1. All amplicons were sequenced using the ABI PRISM Big Dye Terminator Cycle Sequencing Ready Reaction kit (Applied Biosystems -2- Inc, USA).

Table 1. Primer sequences of the carbapenemases encoding genes

| Target genes | Name of primers | Sequence | Amplicon size | Reference |

S1-PFGE and southern blot
The total bacterial DNA was first prepared in agarose plugs, digested with S1 nuclease (Takara, Japan) and further separated by PFGE, as reported previously (21). The DNA fragments were transferred horizontally to a nylon membrane (Millipore, USA), hybridized with digoxigen in-labeled bla probe and then detected using a nitroblue tetrazolium/5-bromo-4-chloro-3’-indolyl-phosphate color detection kit (Roche Applied Sciences, USA).

Filter mating experiment
Filter mating experiment was performed with the rifampin-resistant EC600 and azide-resistant E. coli J53 as the recipient strains. The transconjugants were selected on Mueller-Hinton agar plates containing [ampicillin (50 mg/l) and rifampicin (1024 mg/l)] or [ampicillin (50 mg/l) and NaN (200 mg/l)], respectively, and incubated for 16–18 hr at 37 °C. The successful transconjugants were selected on Mueller-Hinton agar incorporating the same concentration of antibiotics mentioned above. The transformants would be confirmed the resistant genes by PCR.

Plasmid construction and electrotransformation
The plasmid DNA of isolate AB34 was extracted, digested by restriction enzyme EcoRI or SacI and then cloned into the cloning vector pPet28a. The conjugant...
was electrotransformed to *E. coli* DH5α competent cells and selected on Mueller-Hinton agar plates containing ampicillin (50 mg/L) in order to obtain the *E. coli* clone expressing the corresponding carbapenemase enzyme.

**Genetic surroundings detection**

A total genomic sample of *A. pittii* strain AB34 was extracted and purified using the Wizard Genomic DNA purification kit (Promega Corporation, Madison, WI) according to the manufacturer’s instructions. DNA concentration was estimated using a Qubit dsDNA HS Assay Kit and a Qubit 3.0 Fluorometer (Invitrogen, Thermo Fisher Scientific, USA). Extracted DNA was then sequenced with a standard 2×125 paired-end runs protocol on an Illumina HiSeq 2000 (Illumina, San Diego, CA, USA). The quality of the high-throughput sequence data was assessed by FastQC (http://www.bioinformatics.babraham.ac.uk/projects/fastqc/). Raw sequence reads were then *de novo* assembled using Plasmid SPAdes 3.9.0 (http://bioinf.spbau.ru/spades)(22), in order to identify plasmid contigs, and the quality was assessed by QUAST (http://quast.bioinf.spbau.ru).

**Nucleotide sequence accession numbers**

The *bla*<sub>OXA-58</sub> or *bla*<sub>NDM-1</sub> nucleotide sequences are available in GenBank under the accession number KF208466 or KF208467, respectively.

**Results**

**Susceptibility results**

The isolate AB34 was resistant to all β-lactams including ceftazidime, cefepime and carbapenems as well as ampicillin/sulbactam inhibitor combinations, but remained susceptible to cotrimoxazole, tobramycin, ciprofloxacin, levofloxacin and tigecycline (Table 2).

**Detection of carbapenemases encoding genes**

Only OXA-58(599bp) and NDM-1(720bp) were detected in this strain. The amplified products were confirmed by sequencing. BLAST version 2.2.24 (http://blast.ddbj.nig.ac.jp/) was used to process the sequencing data and identify genes.

**Location of *bla*<sub>OXA-58</sub> and *bla*<sub>NDM-1</sub> genes**

After PFGE (Figure 1) and southern blot hybridization (Figure 2), it was found that both *bla*<sub>OXA-58</sub> and *bla*<sub>NDM-1</sub> genes resided on a same 310.1-336.5kb plasmid. Horizontal transfer of the two carbapenem resistance determinants from AB34 to EC600 or *E. coli* J53 was not detected in filter mating.

**Genetic surroundings**

A BLAST search against all completely sequenced *bla*<sub>OXA-58</sub> and *bla*<sub>NDM-1</sub>-genes-co-harboring plasmids in GenBank (http://www.ncbi.nlm.nih.gov/GenBank/)
showed that the \textit{blaOXA-58} gene in AB34 was located downstream of the shortened ISA\textit{ba}3 gene, and upstream of a complete copy of ISA\textit{ba}3 gene (Figure 3). The \textit{blaNDM-1} gene cluster of AB34 was arranged sequentially as ISA\textit{ba}125, \textit{aphA6}, \textit{blaNDM-1}, \textit{bleMBl}, \textit{ΔtrpF}, \textit{dsbD}, \textit{cutA1}, \textit{GroES}, \textit{UmuD}, hypothetical protein, site-specific DNA methylase-like, \textit{ISAba}31-like, dihydrofolate reductase putative membrane protein, C-5 cytosine-specific DNA methylase family protein, ISA\textit{ba}14-like from right to left (Figure 4).

**Discussion**

Since the last decade, carbapenemase-producing \textit{Acinetobacter} spp. have disseminated rapidly throughout the world, posing an urgent threat to public health (1, 23). \textit{A. pittii}, formerly named \textit{Acinetobacter genOMIC species} 3, is increasingly recognized as a clinically important pathogen within the \textit{Acinetobacter calcoaceticus–A. baumannii complex}, which addresses a particular concern due to its competency to acquire multidrug resistance against a wide range of antimicrobial agents (24).

The first known \textit{OXA-58}-producing \textit{Acinetobacter} strain was isolated in France in 2003 (9). It shares less than 50\% of amino-acid homology with oxacillinase. OXA-58 is a widely spread carbapenem-hydrolyzing class D \β-lactamases (CHDLs) that has been reported in \textit{Acinetobacter} spp. from Europe (25), Asia (26), Australia (27), the United States (28) and many Asian countries (29). Though OXA-58 shows only low carbapenem-hydrolyzing activity \textit{in vitro}, the insertion sequence upstream of \textit{blaOXA-58} enhances its transcription greatly and mediates resistance to carbapenems (30-32). It is speculated that the insertion of other IS elements into ISA\textit{ba}3-like could generate a hybrid promoter to enhance the transcription of \textit{blaOXA-58} and mediate greater carbapenem resistance than the intact ISA\textit{ba}3-like element as previously reported (32,33). However, in China, the most common carbapenemase-producing type of \textit{A. baumannii} is OXA-23, while OXA-58 is rarely reported (34).

The NDM-1 gene encodes an enzyme that hydrolyses and inactivates all \β-lactam antibiotics including carbapenems, except for aztreonam, and thus induces resistance to carbapenems (35). \textit{A. baumannii} carrying NDM-1 have been reported from clinical and environmental isolates in several countries (36-39). Not only \textit{Acinetobacter} spp. act as reservoirs for \textit{blaNDM} genes in non-human settings, as recently shown in several Chinese studies with identification of NDM-1-producers among \textit{A. calcoaceticus} and \textit{Acinetobacter junii} from environmental samples from livestock farms (40), \textit{Acinetobacter johnsonii} from hospital sewage (40) and \textit{Acinetobacter lwoffii} from chickens (40), but also act as a source of \textit{blaNDM} genes that horizontally transferred to enterobacterial species as evidenced (41).

It is noteworthy that coexistence of \textit{blaNDM} and \textit{blaOXA} has been described in \textit{Acinetobacter} e.g. \textit{blaOXA-23} and \textit{blaNDM-1} in \textit{A. baumannii} from India (42) and the Czech Republic (43), and \textit{blaNDM-1}, \textit{blaOXA-58} and \textit{bla44551} in \textit{A. baumannii} from China (44). However, it remains unclear whether and how these co-existing carbapenemase genes are expressed to contribute to drug resistance.

\textit{A. pittii} 44551 was recovered from a patient with gout combined with tuberculosis and was found to harbor the carbapenemase genes \textit{blaNDM-1} and \textit{blaOXA-58} on two different plasmids pNDM-44551 and pOXA58-44551, respectively, from China in 2015 (1). Emergence of ST119 \textit{A. pittii} AP 882 co-harbouring NDM-1 and OXA-58 in Malaysia was reported as well, of which genes encoding NDM-1 and OXA-58 resided on an ca.140 kb mega plasmid and a 35 kb plasmid, respectively (45).

Similarly, in our present study, AB34 was isolated and detected co-harbouring OXA-58 and NDM-1-carbapenemase producing residing on the same 310.1-336.5kb plasmid. However, horizontal transfer of carbapenem resistance determinants from AB34 to \textit{EC600} or \textit{E. coli} J53 (AzR) was not detected in filter mating experiment. The up-stream and down-stream of OXA-58 gene in AB34 are ISA\textit{ba}3, which shows 99\% similarity to \textit{A. pittii} pOXA-58-44551 (1). It is reported that the structure of OXA-58 of \textit{A. pittii} 44551 is 372F-IS\textit{ba}3-like-\textit{blaOXA-58}-ISA\textit{ba}3, where the \textit{blaOXA-58} contributed little to \β-lactams resistance due to a lack of the \textit{blaOXA-58}-driven promoter (1). An intact \textit{ISAba}3-like element upstream of \textit{blaOXA-58} has been linked to a lower level of resistance to imipenem compared with \textit{blaOXA-58} with hybrid promoters such as IS6 family-\textit{ISAba}3-like-\textit{blaOXA-58}.

The upstream of NDM-1 of AB34 is ISA\textit{ba}125, while the down-streams are arranged sequentially as \textit{aphA6}, \textit{blaNDM-1}, \textit{bleMBl}, \textit{ΔtrpF}, \textit{dsbD}, \textit{cutA1}, \textit{GroES}, \textit{UmuD}, hypothetical protein, site-specific DNA methylase-like, \textit{ISAba}31-like, dihydrofolate reductase putative membrane protein, C-5 cytosine-specific DNA methylase

**Figure 3.** Analysis of \textit{blaOXA-58}-carrying composite transposon in \textit{Acinetobacter Pittii} AB34 genome. Genes and transcription orientations are indicated by arrows

**Figure 4.** Analysis of \textit{blaNDM-1}-carrying composite transposon in \textit{Acinetobacter Pittii} AB34 genome. Genes and transcription orientations are indicated by arrows
family protein, ISAba14-like, which was with 99% sequence identity against that of Acinetobacter iwoffii pNDM-BJ01 from Beijing, China (46). It is proved that the genetic surroundings of blaNDM-1 is an important vector to mediate to integration and transfer. It should be noted that the ISaba125 element upstream of blaNDM-1 is usually intact in Acinetobacter but often truncated in Enterobacteriaceae, suggesting the probable spread of the blaNDM-1 genetic platforms from Acinetobacter to Enterobacteriaceae (47-50).

Conclusion

This study has improved awareness of the urge of carbapenemase-producing A. pittii isolates in China. Further investigations on the comparative genomic analysis of a large-scale sampling of A. pittii strains from a wide spatial and temporal range in the context of genomic epidemiological characteristics are currently on the way. These data highlight the molecular mechanisms contributing to the rapid development of antimicrobial resistance and will facilitate to expand our understanding of the global public health concern caused by Acinetobacter spp.
