Abstract

We study properties of static, asymptotically AdS black holes in Lovelock gravity. Our main result is a Smarr formula that gives the mass in terms of geometrical quantities together with the parameters of the Lovelock theory. As in Einstein gravity, the Smarr formula follows from applying the first law to an infinitesimal change in the overall length scale. However, because the Lovelock couplings are dimensionful, we must first prove an extension of the first law that includes their variations. Key ingredients in this construction are the Killing–Lovelock potentials associated with each of the higher curvature Lovelock interactions. Geometric expressions are obtained for the new thermodynamic potentials conjugate to the variation of the Lovelock couplings.

1. Introduction

Lovelock theories [1] are an intriguing subset of higher curvature gravity theories. While the field equations for a general higher curvature theory involve second derivatives of the Riemann tensor, Lovelock theories share the property of Einstein gravity that no derivatives of the curvature tensor, and hence only second derivatives of the metric tensor, arise. It follows that Lovelock gravities share a number of additional nice properties with Einstein gravity that are not enjoyed by other more general higher curvature theories. Most prominently, Lovelock gravities can have stable, ghost-free, constant curvature vacua [2, 3] and hence are suitable starting points for quantization\textsuperscript{3}. For the purposes of this paper it will be particularly useful that

\textsuperscript{3} Not all constant curvature vacua of Lovelock gravity theories are stable and ghost free. A recent analysis [4] of the Lovelock gravity theory including up to curvature squared terms found that in the region of parameter space supporting two constant curvature vacua, typically one was stable and one was unstable. See also [5] for a related discussion including the Lovelock curvature-cubed terms in $D = 7$ with three dimensions compactified.
the second-order character of the Lovelock field equations leads to a reasonably well-behaved Hamiltonian formulation of the theory [6].

Lovelock gravity theories have been studied by many authors over a wide span of years. In particular, exact, static black hole solutions were found beginning with the work of the authors of [7–9] (see also the recent reviews [10, 11]). An expression for the entropy of Lovelock black holes was obtained in [12] by means of integrating a first law that was derived using the Hamiltonian perturbation theory techniques of [13] (see also [14] for the entropy of asymptotically AdS black holes with flat and negatively curved horizons). The entropy formula includes new contributions coming from the higher curvature terms in the action and is in agreement with the entropy formula obtained later via more general methods in [15, 16]. There has also been considerable recent interest in Lovelock gravities in the context of the AdS/CFT correspondence [17–27], while stability of static Lovelock black holes under perturbations has been addressed in [28–33].

This paper extends to Lovelock gravities a line of inquiry that was initiated in [34, 35]. In [35] we studied certain thermodynamic properties of black holes in Einstein gravity with a nonzero cosmological constant \( \Lambda \). Geometrical techniques were used to derive a Smarr formula and also a related extension of the first law that includes variations \( \delta \Lambda \) in the cosmological constant. The resulting Smarr formula has the form

\[
(D - 3)GM = (D - 2) \frac{\kappa A}{8\pi} - 2 \frac{\Theta A}{8\pi},
\]

where \( M \) is the ADM mass of the black hole, \( \kappa \) and \( A \) are the surface gravity and area of the horizon, and \( \Theta \) represents a new potential that is thermodynamically conjugate to \( \Lambda \). For \( \Lambda = 0 \), equation (1) reduces to the well-known result [37] for static, asymptotically flat black holes. The extension to \( \Lambda \neq 0 \) had been previously established based on the analysis of the explicit Schwarzschild–(A)dS solutions [38–44]. However, no general derivation was given, and although explicit expressions for the potential \( \Theta \) were obtained in terms of \( M \) and \( \Lambda \), its geometric significance could not be addressed by these means.

There are two ways to derive the Smarr formula for \( \Lambda = 0 \), both of which were generalized to \( \Lambda \neq 0 \) in [35]. Both of these derivations may also be extended to Lovelock gravity theories. Although we will only present the second method here for the Lovelock case, it will be worthwhile to briefly discuss the first method as well. The first method makes use of Komar integral relations [45], which are Gauss' law or Stokes' theorem-type statements that hold on a spatial slice in a spacetime with a Killing vector. For a static black hole with \( \Lambda = 0 \), the Komar integral relation for the time translation Killing vector yields an equality between a boundary integral at infinity proportional to \( M \) and one at the black hole horizon proportional to \( \kappa A \). The extension to \( \Lambda \neq 0 \) had been previously established based on the analysis of the explicit Schwarzschild–(A)dS solutions [38–44]. However, no general derivation was given, and although explicit expressions for the potential \( \Theta \) were obtained in terms of \( M \) and \( \Lambda \), its geometric significance could not be addressed by these means.

An improved Komar integral relation for the \( \Lambda \neq 0 \) case was introduced in [34] and applied in [35] to establish equation (1). In the improved relation, the volume source term proportional to \( \Lambda \) is written as a total divergence and converted to a boundary integral. The new boundary integrand is proportional to the antisymmetric Killing potential \( \xi^a \), related to the Killing vector \( \xi^a \) through

\[
\xi^b = \nabla_a \mu^{ab}.
\]
The combination of this new boundary integral with the original Komar integral at infinity now yields a finite result, eliminating the need for regularization and renormalization. The improved Komar integral relation then yields the Smarr formula (1), including an expression for the potential $\Theta$ in terms of the difference between integrals of the Killing potential at the horizon and infinity.

The second method of establishing the Smarr formula for $\Lambda = 0$ is via the first law $\delta(GM) = \kappa \delta A / 8\pi$. In order for the first law to be satisfied by an overall change in the length scale $L$, in which the quantities $GM$ and $A$ scale as $L^{D-3}$ and $L^{D-2}$, respectively, the mass and area must be related as in (1). As noted in [47], in order to apply this method with $\Lambda \neq 0$ one needs a version of the first law in which the cosmological constant $\Lambda$, which scales as $L^{-2}$, is also allowed to vary. The derivation of such an extended first law in [35] also makes use of the Killing potential $\beta^{ab}$ and ultimately yields the same expression for the potential $\Theta$ in equation (1) as using Komar integrals.

The construction of improved Komar integral relations given in [34] applies to all Lovelock gravity theories, the addition of the cosmological constant term to Einstein gravity being the simplest case in which it is necessary. The key ingredient in the construction is a sequence of Killing–Lovelock potentials $\beta^{(k)ab}$ (defined below) that are in one-to-one correspondence with the higher curvature terms $L^{(k)}$ (also given below) in the Lagrangian of a Lovelock gravity theory. We will follow the first law method described above to derive the Smarr formula for static, asymptotically AdS Lovelock black holes. The required extension of the first law includes variations $\delta b_k$ of each of the dimensionful coupling constants $b_k$ of the Lovelock theory. It has the general form

$$\delta(GM) = \kappa \delta \hat{A} / 8\pi - \frac{1}{16\pi} \sum_k \Psi^{(k)} \delta b_k,$$

(3)

where the quantity $\hat{A}$ defined in equation (9) below is related to the black hole entropy by $S = \hat{A} / 4G$, and the quantities $\Psi^{(k)}$ are new thermodynamic potentials conjugate to the individual Lovelock couplings $b_k$. The central result of the paper is the expression (37) that we derive for the $\Psi^{(k)}$. We find that there are three contributions to this result. The first, which we write as $\Psi^{(1)}$, is given in terms of boundary integrals of the Killing–Lovelock potentials. It can be thought of as coming from the variation of the effective stress–energy introduced by the higher curvature Lovelock interactions. The second and third contributions come from the explicit dependence of the mass and entropy on the Lovelock couplings. In the simple case of Einstein gravity with a nonzero cosmological constant $\Lambda$ studied in [35], only the first of these contributions arose, because the mass and entropy have no explicit dependence on $\Lambda$.

Given the extended first law, it is then straightforward to derive the Smarr formula via the scaling argument discussed above. The quantity $\hat{A}$ scales in the same way as the horizon area, while the Lovelock couplings scale as $L^{2(k-1)}$, giving the result

$$(D - 3)M = (D - 2)T S - \sum_k 2(k - 1) \frac{\Psi^{(k)} b_k}{16\pi G},$$

(4)

where the relation between the temperature and surface gravity $T = \kappa / 2\pi$ has now been used. The Smarr formula gives the mass of a static, asymptotically AdS black hole in terms of certain thermodynamic properties, the surface gravity, entropy and the potentials $\Psi^{(k)}$. It becomes particularly useful when such solutions are not known explicitly, as is the case in higher order Lovelock theories [9]. In the concluding section we will indicate how the Smarr formula may be used in analyzing the Hawking–Page [48] phase transition in general Lovelock gravity theories.
The remainder of the paper is organized as follows. Section 2 summarizes the basic formalism of Lovelock gravity including, in particular, the Killing–Lovelock potentials and the Hamiltonian formulation of the theory. In section 3 we use Hamiltonian perturbation theory techniques to prove the extended first law for Lovelock gravities, including variations in the Lovelock couplings. The final result for the Smarr formula then follows from the scaling argument sketched above. Section 4 contains concluding remarks including some directions for future research.

2. Lovelock gravity

Lovelock gravities [1] are the unique higher curvature gravity theories with field equations that do not involve derivatives of the Riemann curvature tensor. In the subsections below, we will present the parts of the formalism of Lovelock gravity that are needed for our derivations of the extended first law and Smarr formula.

2.1. Lagrangian and equations of motion

The Lagrangian of a Lovelock gravity theory is given by

\[ \mathcal{L} = \sum_{k \geq 0} c_k \mathcal{L}^{(k)} \]

where the \( c_k \) are real coefficients specifying the theory and the \( \mathcal{L}^{(k)} \) are particular scalar contractions of \( k \) powers of the Riemann tensor given by

\[ \mathcal{L}^{(k)} = \frac{1}{2^k} \delta_{\alpha_1 \alpha_2 \ldots \alpha_{2k}}^{\beta_1 \beta_2 \ldots \beta_{2k}} R_{\alpha_1 \beta_1} c_{\alpha_2 \beta_2} \ldots R_{\alpha_{2k} \beta_{2k}} c_{\alpha_{2k-1} \beta_{2k-1}}. \]  

(5)

Here the \( \delta \) symbol is the totally anti-symmetrized product of Kronecker deltas \( \delta_{\alpha_1 \ldots \alpha_n}^{\beta_1 \ldots \beta_n} = n! \delta_{[\alpha_1} \ldots \delta_{\alpha_n]}^{\beta_1 \ldots \beta_n} \), which is normalized so that it takes nonzero values \( \pm 1 \). By definition, the zeroth-order term in the curvature is given by \( \mathcal{L}^{(0)} = 1 \), while the linear term is normalized so that \( \mathcal{L}^{(1)} = R \). The term quadratic in the curvature, known as the Gauss–Bonnet term, is given by \( \mathcal{L}^{(2)} = R_{ab} c^d R_{cd} a^b - 4 R_a^b R_{ab} + R^2 \).

A given term \( \mathcal{L}^{(k)} \) in the Lovelock Lagrangian can only contribute to the dynamics in dimensions \( D > 2k \). For \( D < 2k \), \( \mathcal{L}^{(k)} \) is easily seen to vanish identically, while for \( D = 2k \) its integral is proportional to the topologically invariant Euler character of the manifold. It follows that the variation of \( \mathcal{L}^{(k)} \) in \( D = 2k \) is a total derivative and does not contribute to the equations of motion. This is the case e.g. for the Einstein term \( \mathcal{L}^{(1)} = R \) in \( D = 2 \) and for the Gauss–Bonnet term \( \mathcal{L}^{(2)} \) in \( D = 4 \). The Gauss–Bonnet term only contributes to the dynamics of theories for \( D \geq 5 \). More generally, the Lovelock Lagrangian in \( D \) spacetime dimensions can be taken to be the truncated sum

\[ \mathcal{L} = \sum_{k=0}^{\hat{k}} c_k \mathcal{L}^{(k)}, \]

(6)

where \( \hat{k} = [(D - 1)/2] \). The field equations for Lovelock gravity have the form \( \mathcal{G}^{ab}_a = 0 \) where \( \mathcal{G}^{ab}_a = \sum_k c_k \mathcal{G}^{(k)a}_b \), with the individual Einstein-like tensors \( \mathcal{G}^{(k)a}_b \) given by

\[ \mathcal{G}^{(k)a}_b = -\frac{1}{2^{k+1}} \delta_{\alpha_1 \beta_1 \ldots \alpha_{2k} \beta_{2k}}^{\gamma_1 \delta_1 \ldots \gamma_{2k} \delta_{2k}} R_{\gamma_1 \delta_1} c_{\gamma_2 \delta_2} \ldots R_{\gamma_{2k} \delta_{2k}} c_{\gamma_{2k-1} \delta_{2k-1}}. \]  

(7)

Because the field equations do not contain any derivatives of the curvature tensor, we see explicitly that the equations of motion do not involve any derivatives of the metric higher than the second order. Since the terms \( \mathcal{L}^{(k)} \) are diffeomorphism invariant, each of the Einstein-like tensors \( \mathcal{G}^{(k)a}_b \) satisfies \( \nabla_a \mathcal{G}^{(k)a}_b = 0 \).
2.2. Including a factor of Newton’s constant

In the case of pure gravity, an overall rescaling of the gravitational action does not change the equations of motion. When gravity is coupled to matter a factor of $1/16\pi G$ is typically written in front of the gravitational action, which defines the strength of the coupling of gravity to matter. Even though we are studying vacuum spacetimes in this paper, it will be useful later on to work with rescaled Lovelock parameters $b_k$ defined by

$$c_k = \frac{b_k}{16\pi G} \tag{8}$$

so that an overall factor of $1/16\pi G$ will multiply the gravitational action. The parameters $b_k$ then have dimensions $L^{2(k-1)}$, with $b_1$ being dimensionless. In general, the total Lagrangian is a sum of the Lovelock Lagrangian plus a contribution from matter fields, and then the field equations are $\mathcal{G}^{ij} = \sum_k b_k \mathcal{G}^{(k)}_{ij} = 8\pi G T_{ij}$. Of course the distinction between the $c_k$ and the $b_k$ is hidden when one works in units with $G = 1$, which gives mass the same units as length, but keeping factors of $G$ explicit will be important for identifying physical quantities and their scaling dimensions.

2.3. Black hole entropy

We will also need the formula for black hole entropy in Lovelock gravity, which was obtained in [12] by integrating the first law for Lovelock black holes (with fixed Lovelock couplings). First define the quantities

$$\hat{A} = \sum_k b_k A^{(k)}, \quad A^{(k)} = k \int_H da \mathcal{L}^{(k-1)} \tag{9}$$

where the integral is taken over the intersection of the black hole horizon with a spacelike slice and the Lovelock term $\mathcal{L}^{(k-1)}$ is evaluated with respect to the induced metric on this cross-section of the horizon. The black hole entropy is then given by

$$S = \frac{1}{4G} \hat{A}. \tag{10}$$

Note that $\mathcal{L}^{(0)} = 1$ and therefore $A^{(1)}$ is simply the horizon area, reproducing the familiar result of Einstein gravity, while the Gauss–Bonnet term in the original Lovelock action will make a contribution to the entropy proportional to the integral of the scalar curvature over the horizon. The fact that the entropy has explicit dependence on the Lovelock couplings will be important below when we consider the effect of varying these couplings.

2.4. Killing–Lovelock potentials

The Killing–Lovelock potentials [34] which play an important role in our construction arise in the following way. The Stokes theorem implies that a divergence-free vector field may be written, at least locally, as the divergence of an anti-symmetric two-index tensor. Killing vectors are divergenceless and hence a Killing vector $\xi^a$ can be expressed in terms of an anti-symmetric Killing potential as $\xi^b = \nabla_a \beta^{ab}$. The Killing potential $\beta^{ab}$ is not unique but can be shifted by the addition of a divergenceless tensor.

Further, each Einstein-like tensors $\mathcal{G}^{(k)}_{ab}$ may be contracted with the Killing vector $\xi^a$ to give the divergenceless currents $\mathcal{J}^{(k)}_{ab} = \mathcal{G}^{(k)}_{ab} \xi^b$. The Killing–Lovelock potentials $\beta^{(k)ab}$ are then defined to be solutions of

$$\mathcal{J}^{(k)}_{ab} = -\frac{1}{2} \nabla_a \beta^{(k)ab}. \tag{11}$$
where the coefficient $-1/2$ on the right-hand side is introduced for later convenience. The Killing–Lovelock potentials are defined only up to the addition of an arbitrary divergenceless tensor. From equation (7), we see that $G_{ab}^{1/2} = -(1/2)\delta^a_b$ and hence $\beta^{1/2}$ is simply the Killing potential. The Killing potential played an important role in the derivation of the Smarr formula with $\Lambda \neq 0$ and the first law with varying $\Lambda$ in [35]. The Killing potentials with $k > 0$ will play similar roles in our construction below.

2.5. Constant curvature vacua

A Lovelock gravity theory in $D$ spacetime dimensions, specified by a set of coefficients $c_0, \ldots, c_k$, can have between 0 and $k$ distinct constant curvature vacua. These vacua determine the possible asymptotic behaviors for black hole solutions of Lovelock gravity. The possible vacuum curvatures may be found by rewriting the overall Einstein-like tensor $G_{ab}$ in the form

$$G_{ab} = \alpha \delta_{ef} \delta_{eg} \delta_{dh} \delta_{gf} \left( R_{cd} e_i f_i - \alpha_1 \delta_{ef} f_i \right) \left( R_{cd} e_i f_i - \alpha_2 \delta_{gf} f_i \right).$$

(12)

Through use of the identity

$$\delta_{h_1 b_1} \delta_{a_1 p a_1 b_p} b_{p+1} = 2(D-p+1)(D-p+2)\delta_{h_1 b_1} b_{p+2},$$

(13)

one can see that this is equivalent to the original form given in section 2.1. The real-valued coefficients $b_1$ in the Lovelock Lagrangian are given by sums of products of the new coefficients $\alpha_1$ in (12) (the explicit relations are given in [49]). Inverting this relation to get the $\alpha_k$’s in terms of the $b_1$’s would require solving a system of algebraic equations that are of order $k$ in their variables. Hence some, or all, of the coefficients $\alpha_k$ may be complex. If some particular coefficient $\alpha_p$ is real, it follows that a spacetime with constant curvature given by $R_{ab} = \alpha_p \delta_{ab}$ solves the equations of motion $G_{ab} = 0$. Our primary interest will be in asymptotically AdS black holes, and we will therefore assume that we are working with a Lovelock gravity theory having at least one $\alpha_k$ real and negative.

2.6. Hamiltonian formulation

The Hamiltonian formulation of Lovelock gravity given in [6] was used in [12] to derive a first law and the expression (10) for the gravitational entropy in Lovelock theories. We will make similar use of the Hamiltonian formalism in combination with the Killing potentials to derive an extended first law in which the Lovelock coupling constants are allowed to vary. As usual, the spacetime metric is split according to

$$g_{ab} = -n_a n_b + s_{ab}, \quad n_a n^a = -1, \quad s_{ab} n_b = 0,$$

(14)

where $n^a$ is the unit timelike normal to a spatial slice $\Sigma$ and $s_{ab}$ is the induced metric on $\Sigma$. The canonical variables are the spatial metric $s_{ab}$ and its conjugate momentum $\pi_{ab}$. We consider Hamiltonian evolution along a vector field $\xi^a$, which can be written in the projected form as $\xi^a = F n_a + F' s_{ab} \xi^b$. The Hamiltonian is then given by $H = \int \sqrt{s} H$ where $H = F H_\perp + F' H_\parallel$. Here as in Einstein gravity the quantities $H_\perp$ and $H_\parallel$ are proportional to the components of the Einstein-like tensor $G_{ab}$ with one index contracted with the normal $n^a$ and the other index projected normal to or parallel to the surface, respectively,

$$H_\perp = -2G_{ab} n^a n^b, \quad H_\parallel = -2s_{ab} n^a G_{bc}.$$

(15)

4 Although it is not relevant for our discussion (or the derivation of the first law with fixed Lovelock coupling constants in [12]), it should be noted that the Hamiltonian formulation of Lovelock gravity is generally ill-defined [6] in the sense that the ‘velocities’ are multi-valued functions of the momenta. The exception to this is when all the parameters of the theory are such that all the $\alpha_k$’s in equation (12) are equal and there is a unique constant curvature vacuum.
Also as in Einstein gravity, the lapse $F$ and shift $F_a$ are Lagrange multipliers. One can further decompose the Hamiltonian order by order in the curvature as $H = \sum_k b_k H^{(k)}$ with $H^{(k)} = F H_L^{(k)} + F^a H_a^{(k)}$, $H_L^{(k)} = -2G^{(k)}_{ab} n^a n^b$ and $H_a^{(k)} = -2s_a^{(k)} n^r \xi_r^{(k)}$. Adding in the stress–energy tensor for later reference, the Hamiltonian and momentum constraint equations are given by $H_L = -16\pi G \rho$ and $H_a = -16\pi G J_a$, where $\rho = n^a n^b T_{ab}$ and $J_a = s_a^b n^r T_{bc}$.

For a stationary black hole of Lovelock gravity, one can consider Hamiltonian evolution of the initial data with respect to the horizon-generating Killing field $\xi^a$, with corresponding lapse $F$ and shift vector $F_a$. For this choice of vector field the individual terms $H^{(k)}$ in the decomposition of the Hamiltonian $H$ can each be re-written as a total divergence in terms of the Killing potentials $\beta^{(k)ab}$ introduced in section 2.4. One has

$$H^{(k)} = F H_L^{(k)} + F^a H_a^{(k)} = -2G^{(k)}_{ab} \xi_r^{(k)} n_d = D_c (\beta^{(k)cd} n_d),$$

where $D_a$ is the covariant derivative operator associated with the spatial metric $s_{ab}$.

### 3. Lovelock first law with varying couplings

The Smarr formula in Einstein gravity may be obtained from the first law by considering perturbations that represent an overall change in the length scale (see e.g. [50, 51]). Lovelock gravity theories, however, include additional dimensionful couplings, and in order to obtain the Smarr formula in a similar fashion, one must start with a version of the first law that includes variations in the Lovelock couplings. The need for such an extended first law already arises for Einstein gravity with a nonzero cosmological constant [47]. The contribution to the first law from a varying cosmological constant was computed and used to obtain the Smarr formula in [35].

A first law for Lovelock black holes with fixed coupling constants was derived in [12] using the Hamiltonian perturbation theory methods of [13] (see [52] for a more general formulation). Limiting our consideration to perturbations around static black holes, the result of [12] has the familiar form

$$\delta M|_{b_k} = T \delta S|_{b_k},$$

where the temperature is given in terms of the surface gravity $\kappa$ by $T = \kappa / 2\pi$, the entropy $S$ is given in equation (10) and we indicate explicitly that we are considering variations with the Lovelock couplings held fixed. In this section we will compute the new contributions to (17) that arise when the Lovelock couplings are allowed to vary.

#### 3.1. Hamiltonian perturbation theory

The Hamiltonian perturbation theory construction works in the following way. Let the metric be split as in equation (14). The Hamiltonian variables are the metric on the spacelike slices $s_{ab}$ and its conjugate momentum $\pi_{ab}$. We first recall the case where the Lovelock coupling constants are held fixed [12] and then show how allowing variations in the couplings modifies the results. Let the metric $g^{(0)}_{ab}$ be a solution to the equations of motion with a static Killing vector $\xi^a$. The corresponding Hamiltonian variables are $s_{ab}^{(0)}$ and $\pi_{ab}^{(0)}$ and satisfy $L_{\xi} s^{(0)}_{ab} = L_{\xi} \pi_{ab}^{(0)} = 0$. Now consider perturbing the metric such that $s_{ab} = s_{ab}^{(0)} + \delta s_{ab}$ and $\pi_{ab} = \pi_{ab}^{(0)} + \delta \pi_{ab}$. The perturbed metric is also assumed to satisfy the equations of motion.

5 One might wonder how the scaling argument in Einstein gravity could have given the correct result without using a first law that includes variations $\delta G$ in Newton’s constant, since it is also dimensionful. We will address this point below.
but the perturbations are not required to be invariant under the symmetry generated by the Killing vector $\xi^a$.

The variation of $H_\perp$ with respect to these perturbations then takes the form
\[
\delta H_\perp = \frac{\delta H_\perp}{\delta s_{ab}} \cdot \delta s_{ab} + \frac{\delta H_\perp}{\delta \pi^{ab}} \cdot \delta \pi^{ab}
\]
and similarly for the variation $\delta H_a$. Here $\cdot$ indicates that the quantity to the left is a differential operator acting on the quantity to the right.

The construction proceeds by looking at the Hamiltonian evolution with respect to the Killing vector $\xi^a$. The lapse and shift variables $F$ and $F^a$ are then given by the projections of the Killing vector perpendicular to and along the hypersurface, so that $F = -\xi^an_a$ and $F^a = \xi^a - Fn^a$. The variation in the Hamiltonian is then
\[
\delta H = \delta H_\perp + \delta H_a = \delta H_\perp + \delta H_a = \left( \delta H^*_\perp \cdot F + \delta H^*_a \cdot F^a \right) \delta s_{ab} + \left( \delta H^*_\perp \cdot \frac{\delta H_\perp}{\delta \pi^{ab}} \cdot F + \delta H^*_a \cdot \frac{\delta H_a}{\delta \pi^{ab}} \cdot F^c \right) \delta \pi^{ab} + D_{c} B^{c}.
\]
(19)

Note that this applies in vacuum, while more generally perturbations to the stress energy tensor will appear on the right-hand side. Also note that the vector $B^a$ receives a contribution from each higher curvature term so that $B^a = \sum_k b_k B^{(k)a}$. One finds in particular that $B^{(0)a} = 0$, while
\[
B^{(1)a} = F \left( D^a h - D_b h^{ab} \right) - h D^a F + h^{ab} D_b F + \frac{1}{\sqrt{\bar{s}}} (F^a \pi^{bc} h_{bc} - \pi^{ab} h_{bc} F^c - 2 p^{ab} F_b)
\]
(21)
gives the contribution from the Einstein term in the Lagrangian [52]. Here we have set $h_{ab} = \delta s_{ab}$ and $p^{ab} = \delta \pi^{ab}$. An explicit expression for the $B^{(k)a}$ for all $k$ is given in [12] but will not be needed here.

The Gauss law statement (20) was used in [12] to derive the first law in Lovelock theories with fixed $b_k$ and $G$ by integrating over the spatial surface. As in the derivation of the first law in Einstein gravity [13], the boundary term at infinity is found to be proportional to the variation in the ADM mass, while the boundary term at the horizon is proportional to the surface gravity times the variation in the entropy. Setting the whole integral equal to zero then gives the result for the first law with fixed Lovelock couplings in equation (17).

In order to derive the Smarr formula for Lovelock gravity, we now need to compute the contributions to the first law when the Lovelock coupling constants are allowed to vary. We will consider independent variations in all the constants $b_k$ as well as in Newton’s constant $G$. Considering variation in the dimensionless coupling $b_1$ is redundant. However, it makes the computations more uniform to carry through and we will see that the variation $\delta b_1$ drops out from the final result.

3.2. Varying Newton’s constant

In order to understand how variations in Newton’s constant enter the result, let us first reconsider the first law of Einstein gravity coupled to matter allowing for a nonzero $\delta G$. 

8
Take the background to be Minkowski spacetime and include the matter via a perturbative source term $\delta \rho$ (the background stress energy and perturbative current $\delta J_a$ are taken to vanish). Adding the contributions of stress–energy into the perturbation theory presented above, the Hamiltonian constraint equation $H = -16\pi G \rho$ linearizes to $D_a B^a = -16\pi \delta (G \rho)$, where $B^a = B^{(1)a}$ is given in equation (21). Integrating this result over a spatial slice, we have

$$\int_\infty da c B^{(1)c} = -16\pi \delta (GM).$$

(22)

Note that the background is Minkowski spacetime, so there is no internal boundary at a black hole horizon. However, this result for the boundary term at infinity will continue to hold with a black hole present and therefore with $\delta G \neq 0$, the first law becomes

$$\delta (GM) = \frac{\kappa}{8\pi} \delta A.$$  

(23)

Of course if $G$ is fixed then this is much ado about nothing. However, to derive the Smarr relation from the resulting first law, one must understand that the actual result is (23). One gets the right result because the product $GM$ has dimension $L^{D-3}$ which is not true for the mass $M$ by itself.

Applying this same reasoning to the results of [12] in Lovelock gravity, we modify the equation for $\delta M$ to replace $G\delta M$ with $\delta (GM)$ giving

$$\delta (GM) = -\frac{1}{16\pi} \int_\infty da c \sum_k b_k B^{(k)c}$$

(24)

which holds for fixed couplings $b_k$.

### 3.3. Varying Lovelock couplings

Now consider perturbing the coefficients $b_k$ of the Lovelock theory as well. The perturbed metric is assumed to satisfy the Lovelock equations of motion with the perturbed coefficients $b_k + \delta b_k, G + \delta G$. For vacuum solutions one has $H = \delta H = 0$. Equation (20) will receive a new contribution from the $\delta b_k$, giving

$$D_a B^a + \sum_k \delta b_k \left( F_k^B H_k + F_a H_a^{(k)} \right) = 0,$$

(25)

where $H_k^B$ and $H_a^{(k)}$ are evaluated with respect to the unperturbed variables $\bar{s}_{ab}$ and $\bar{\pi}^{ab}$. Unlike $H_k^B$ and $H_a^{(k)}$ themselves, the sum above with coefficients $\delta b_k$ rather than $b_k$ will not vanish in general. This would appear to spoil the chances of deriving an expanded version of the first law from (25). However, each term in the sum may be rewritten as a boundary term by making use of the Killing–Lovelock potentials $\beta^{(k)cd}$ defined in equation (11). The result of integrating (25) over the spatial slice is then given by

$$\int_{\partial V} da c \sum_k \left\{ b_k B^{(k)c} [h_{ab}] + \delta b_k \beta^{(k)cd} n_d \right\} = 0.$$

(26)

This result will now enable us to derive the generalized first law for Lovelock black holes including variations in the Lovelock couplings. However, there are two issues that need to be resolved in order to process equation (26) into the first law. First is the issue of divergences. With asymptotically AdS boundary conditions, each of the individual terms in (26) diverges at infinity. In order to begin the process of interpreting the contributions at infinity, we will want to work with finite quantities. Second, in Lovelock gravity both the mass (discussed below) and the entropy (10) have explicit dependence on the Lovelock couplings that must be taken into account in identifying the variations $\delta M$ and $\delta S$. 

9
3.4. Dealing with divergences

When the Lovelock couplings $b_k$ are varied, the curvatures of the Lovelock vacua discussed in section 2.5 will vary as well. This leads to divergences in individual terms in the boundary term at infinity contained in equation (26). In this section, we show that adding zero to the boundary integrand at infinity in a judicious way yields finite quantities which will aid in the processing of the first law. This procedure is described in some detail for the case $\hat{k} = 1$, i.e. Einstein gravity with $\Lambda < 0$, in [35]. We will just sketch how it works out in the general Lovelock case.

Let us assume that with Lovelock coupling constants $b_k$ the theory has an AdS vacuum with the radius of curvature $l$. In static coordinates, the AdS vacuum metric is then given by

$$d s^2 = -(1 + r^2/l^2) \, dt^2 + \frac{dr^2}{(1 + r^2/l^2)} + r^2 \, d\Omega_{D-2}^2.$$  \hspace{1cm} (27)

We will call the spatial part of this metric $\bar{s}_{A}$. Now consider varying the Lovelock couplings to nearby values $b_k + \delta b_k$. The AdS curvature radius will generically also shift to a nearby value $l + \delta l$, where to a good approximation $\delta l$ can be taken to depend linearly on the shifts $\delta b_k$ in the Lovelock couplings. We will call this new AdS vacuum metric $\bar{s}_{B}$ and denote the difference between the two AdS metrics by $H_{ab} = \bar{s}_{B} - \bar{s}_{A}$.

Now consider the Gauss law statement (26) for this setup. Since there is no black hole horizon, the only contribution to the boundary integral comes from infinity and (26) implies that this integral at infinity must vanish. Denoting the Killing–Lovelock potentials for the metric $\bar{s}_{A}$ by $\beta(k)_{AdS}$, we then have the relation

$$\int_{\infty} dac \sum_{k} (b_k B(k)c[H_{ab}] + \delta b_k \beta(k)c_{AdS} [H_{ab}] + \Theta_{k}^{(k)})) = 0.$$  \hspace{1cm} (28)

We have checked this formula explicitly by computing all the ingredients, each of which diverges in the limit that the boundary is taken to infinity, with the sum vanishing pointwise. The check for the case $\hat{k} = 1$ is carried out explicitly in [35].

Now consider a static black hole with the metric $s_{A}$ in the Lovelock theory with couplings $b_k$ that is asymptotic at infinity to the AdS vacuum $\bar{s}_{A}$, and also a perturbed black hole with the metric $s_{B}$ in the Lovelock theory with perturbed couplings $b_k + \delta b_k$ that is asymptotic to the AdS vacuum $\bar{s}_{B}$. The metric perturbation $h_{ab} = s_{B} - s_{A}$ between the black hole spacetimes then asymptotes at infinity to $H_{ab}$. The cancellation of infinities in equation (28) guarantees that the total boundary term at infinity in (26) will be finite. However, in order to work with manifestly finite contributions, we can subtract zero in the form of equation (28) from equation (26), giving

$$0 = \frac{1}{16\pi G} \sum_{k} \left\{ \int_{\infty} d\alpha c b_k (B(k)c[H_{ab}] - B(k)c[H_{ab}]) - \int_{H} d\alpha c b_k B(k)c[H_{ab}] - \delta b_k \Theta_{k}^{(k)} \right\},$$  \hspace{1cm} (29)

where we have grouped together the Killing–Lovelock potential terms into the quantities

$$\Theta_{k}^{(k)} = \int_{H} d\alpha c \beta(k)^{cd} n_{d} - \int_{\infty} d\alpha c (\beta(k)^{cd} - \beta^{(k)cd}_{AdS}) n_{d}.$$  \hspace{1cm} (30)

The terms grouped by parenthesis in the integrals at infinity in (29) and (30) can be shown to sum to finite quantities. With the Gauss law identity processed into the form (29), we are now in a position to identify the contributions to the variations in the mass and entropy and establish the extended first law.
3.5. Extended first law and Smarr formula

The task at hand is now to relate the Gauss law expression (29) to the variations in the mass and entropy. In order to understand the variation $\delta M$ in the mass for Lovelock black holes, we need to start with an expression for the mass $M$ itself. As discussed in [12], the Hamiltonian formulation of Lovelock gravity is well suited to deriving an expression for the mass. Following the reasoning of Regge and Teiltelboim [54] in Einstein gravity, in order to have a well-defined variational principle, the volume term of the Lovelock Hamiltonian must be supplemented by a boundary term, whose variation cancels the boundary term that arises in the variation of the bulk Hamiltonian. The mass $M$ of the spacetime is given by the value of the Hamiltonian. Since the bulk Hamiltonian vanishes on solutions, the mass is given solely by the boundary term. The steps required to obtain the required Hamiltonian boundary term are essentially those of the Hamiltonian perturbation theory that produces $B^0$ in (19). For a metric $s^A_{ab}$, that is asymptotic at infinity to the AdS vacuum with metric $\bar{s}^A_{ab}$, the mass is then given by

$$M[s^A_{ab}] = -\frac{1}{16\pi G} \sum_k b_k \int_{\infty} \omega \left[ B^{(k)X}_{ab}[s^A_{ab} - \bar{s}^A_{ab}] \right].$$

(31)

Note that the explicit dependence of the mass on the Lovelock couplings will contribute to $\delta M$ when these couplings are varied.

Now assume that the nearby metrics $s^B_{ab}$ and $s^A_{ab}$ are as described in section 3.4. Recalling that the boundary vectors $B(k)a$ are linear in their arguments, the variation in the mass $\delta M = M[s^B_{ab}] - M[s^A_{ab}]$ is given by

$$\delta M = -\frac{1}{16\pi G} \sum_k \int_{\infty} \omega \left[ b_k B^{(k)X}[s^B_{ab} - s^A_{ab}] - \left( s^A_{ab} - \bar{s}^A_{ab} \right) \right]$$

(32)

and

$$= -\frac{1}{16\pi G} \sum_k \int_{\infty} \omega \left[ b_k \left( B^{(k)X}[H_{ab}] - B^{(k)X}[H_{ab}] \right) + \delta b_k B^{(k)X}[s^A_{ab} - \bar{s}^A_{ab}] \right].$$

(33)

The other ingredient we need is the variation of expression (10) for the entropy of a Lovelock black hole, which is given by $\delta S = \frac{1}{4 \pi} \sum_k (b_k A(k) + A(k) \delta b_k)$. From the derivation of the first law with fixed Lovelock couplings [12], we know that

$$\delta A(k) = -\frac{1}{2\kappa} \int_H \omega \left[ B^{(k)X}[s^B_{ab} - s^A_{ab}] \right]$$

(34)

while the black hole temperature is related to the horizon surface gravity according to $T = \kappa / 2\pi$. Therefore, we have

$$T \delta S = -\frac{1}{16\pi G} \int_H \omega \left[ b_k \sum_k A(k) \delta b_k \right].$$

(35)

We can now substitute expressions (33) and (35) for $\delta M$ and $T \delta S$ into the Gauss law relation (29) to obtain a first law having the form given in equation (3). If we make the further definition

$$B^{(k)X} = \int_{\infty} \omega \left[ B^{(k)X}[s^A_{ab} - \bar{s}^A_{ab}] \right],$$

(36)

then the thermodynamic potentials $\Psi^{(k)}$ are given by

$$\Psi^{(k)} = 2\kappa A^{(k)} + B^{(k)} + \Theta^{(k)},$$

(37)

with the three terms originating respectively from the dependence of the entropy, the mass and the bulk Hamiltonian on the Lovelock couplings. Note that the quantities $B^{(0)X}$ and $A^{(0)}$ both
vanish and that consequently this general result reduces to that of [35] in the case of Einstein

\[ (D - 3)M = (D - 2)TS - \sum_k \frac{2(k - 1)}{16\pi G} (2\kappa A^{(k)} + B^{(k)} + \Theta^{(k)})b_k. \]

(38)

The formula (37) gives geometrical expressions for the potentials \( \Psi^{(k)} \) that are

thermodynamically conjugate to the Lovelock couplings \( b_k \). One obvious comment is that

these expressions are more complicated than the thermodynamic quantity conjugate to the

entropy (i.e. the temperature) which remains simple in Lovelock gravity. It seems possible

that there exists a simpler formulation for the \( \Psi^{(k)} \). In this context, it is worth noting that the

quantities \( B^{(k)} \) can each be shown to be proportional to the mass [36] according to

\[ B^{(k)} = -k \frac{16\pi G(D - 1)!}{\sigma_1 (D - 2k - 1)!} \left( \frac{-1}{l^2} \right)^{k-1} M, \]

(39)

where \( \sigma_1 = \sum_k \frac{(D - 1)!}{(D - 2k - 1)!} \left( \frac{-1}{l^2} \right)^{k-1} k b_k. \)

3.6. Physical significance of the potentials \( \Theta^{(k)} \)

The terms \( A^{(k)} \) and \( B^{(k)} \) in the expression (37) for \( \Psi^{(k)} \) are somewhat familiar, being related to

the entropy and mass respectively. The terms \( \Theta^{(k)} \), on the other hand, are new and we should

ask what intuition can we gain into them? Let us start by drawing attention to two important

features of the formula (30) for the \( \Theta^{(k)} \)’s.

First, recall that the anti-symmetric Killing–Lovelock potentials \( \beta^{(k)ab} \) are specified only

up to the addition of an arbitrary divergenceless anti-symmetric tensor. The potentials \( \Theta^{(k)} \),

however, are invariant under such shifts (see the discussion of this point in [35]). Second, the

integrals of \( \beta^{(k)ab} \) and \( \beta^{(k)ab}_{\text{AdS}} \) at infinity are individually divergent. To obtain a finite result,

one must take the difference of the two integrals over finite-sized spheres and then take the

limit in which the radius of the sphere becomes infinite. The potentials \( \Theta^{(k)} \) then represent

‘renormalized’ or ‘effective’ quantities.

The physical significance of the potentials \( \Theta^{(k)} \) is perhaps easier to assess by converting

the boundary integrals in (30) back into volume integrals. Making use of equation (16), one can

express the \( \Theta^{(k)} \) in terms of volume integrals of the individual terms \( H^{(k)} \) in the Hamiltonian.

The \( k \)th Hamiltonian function is given explicitly by

\[ H^{(k)} = -\frac{1}{2k} \tilde{\delta}_{a_1b_1...a_kb_k} R_{a_1b_1c_1d_1} [g] \ldots R_{a_kb_kc_kd_k} [g], \]

(40)

where the tilde denotes the anti-symmetrized delta function projected with the spatial metric

\( g_{ab} \) on all its indices. The Riemann tensors here are those of the full spacetime metric.

However, because all indices on the Riemann tensors are projected with the spatial metric,

we can use the Gauss–Codazzi equations to write them in terms of the Riemann tensor for

the spatial metric \( g_{ab} \) together with the extrinsic curvature \( K_{ab} \) of the spatial slice according to

\( \tilde{R}_{ab}^{cd}[g] = R_{ab}^{cd}[x] + K_{a}^{c} K_{b}^{d}. \) Now recall that the spacetime metric is assumed to have a static Killing vector \( \xi^a. \) Let us choose a spatial slice \( \Sigma, \) normal in the direction of the

Killing field, so that \( \xi^a = F n^a. \) For this slice the extrinsic curvature \( K_{ab} \) vanishes and the \( k \)th Hamiltonian becomes

\[ H^{(k)} = -\frac{1}{2k} \tilde{\delta}_{a_1b_1...a_kb_k} R_{a_1b_1c_1d_1} [s] \ldots R_{a_kb_kc_kd_k} [s]. \]

(41)
This is the same as minus the $k$th Lovelock Lagrangian given in (5), but now evaluated on the spatial metric (i.e. for this configuration $H^2 = -L^{(k)}$). Combining equations (16) and (41) the formula (30) for the $\Theta^{(k)}$ can now be written as

$$\Theta^{(k)} = \int_{\Sigma} \sqrt{-g} L^{(k)}[s] - \int_{\Sigma_{\text{AdS}}} \sqrt{-g_{\text{AdS}}} L^{(k)}[s_{\text{AdS}}].$$

(42)

In the first integral, the spatial slice $\Sigma$ runs from the black hole horizon out to spatial infinity, while in the second integral $\Sigma_{\text{AdS}}$ is a spatial slice of AdS and has no internal boundary. In both integrals the slice is chosen to have unit normal such that $\xi^a = F n^a$, and we have combined $\sqrt{-g} = F \sqrt{s}$. As noted above, each of the volume integrals in (42) is divergent and therefore the formula must be understood as integrating out to some large spheres in the asymptotic region and carrying out the subtraction before letting the spheres go to infinity.

The potential $\Theta^{(0)}$ was previously considered in [35]. The 0th Lovelock Lagrangian is simply $L^{(0)} = 1$ and therefore the integrals in (42) are the volumes of the respective slices. Since the slice $\Sigma_{\text{AdS}}$ covers the whole of the interior, while the slice $\Sigma$ has the interior of the black hole removed, we can think heuristically of the difference in (42) as minus an effective volume $V_{\text{eff}}$ of the black hole interior:

$$\Theta^{(0)} = -V_{\text{eff}}.$$ \hspace{1cm} (43)

As noted in [35], thinking about $\Theta^{(0)}$ in this way leads to a thermodynamic interpretation in the case of Einstein gravity with a nonzero cosmological constant $\Lambda = -b_0/2$. The cosmological constant is naturally associated with a pressure through $p = -\Lambda/8\pi G$ and the new terms in the extended first law and Smarr formula in this case become respectively $V_{\text{eff}} \delta p$ and $p V_{\text{eff}}/4\pi G$. The form of this contribution to the first law led us to the interpretation of the mass $M$ as a kind of enthalpy in the context of a variable cosmological constant.

### 4. Concluding remarks and future directions

We have used geometric methods to establish certain properties of static, asymptotically AdS black holes in Lovelock gravity theories, namely a Smarr formula (38) and a related extension of the first law (3) that includes variations in the Lovelock couplings. In addition to the familiar term proportional to the surface gravity times the area, the Smarr formula\(^6\) contains a sum over a set of geometric potentials $\Psi^{(k)}$ multiplied by the Lovelock couplings $b_k$. A similar sum appears in the first law.

The new potentials $\Psi^{(k)}$ in (37) include three types of contributions which we have written as $A^{(k)}$, $B^{(k)}$ and $\Theta^{(k)}$, related to the entropy, mass and Killing–Lovelock potentials, respectively. The terms $\Theta^{(k)}$, in particular, are expressed in terms of boundary integrals of the anti-symmetric Killing–Lovelock potentials $\beta^{(k)ab}$ defined in (11). We have shown that they can be re-expressed as in (42) as finite, renormalized volume integrals of the Lovelock Lagrangian densities over a spatial slice extending from the horizon out to infinity. The AdS/CFT correspondence offers a potentially rewarding direction to look for further insight into the physical significance of the $\Psi^{(k)}$'s. It is well known that the properties of Einstein–AdS black holes are related to those of the high temperature phase of the boundary CFT [55, 56]. As noted in the introduction, the impact of Gauss–Bonnet and higher derivative

---

\(^6\) A Smarr formula for AdS black strings in Einstein–Gauss–Bonnet gravity was found using boundary counterterm methods in [53] which does not include the $\Psi^{(k)}$-type potential terms found here. The solutions studied in [53], including a compact direction, differ in boundary conditions from those considered here and hence our results cannot be compared directly. However, we find the absence of the potential terms in the results of [53] surprising. We expect this is due to the use of different definitions of the mass.
Lovelock terms on the boundary CFT has been the subject of substantial recent interest (see footnote 4). The potentials $\Psi^{(k)}$ should be relevant to this story.

A related application of the Smarr formula that we plan to explore in future work is using it as an aid in the analysis of the free energy of Lovelock black holes. Hawking and Page [48] showed that sufficiently large AdS–Schwarzschild black holes have positive specific heat and are therefore thermodynamically stable. Further, they computed the free energy $F$ as a function of the horizon radius $r_H$ and $\Lambda$, finding a phase transition where the free energy for large black holes relative to the AdS background becomes negative above a certain temperature. Through the AdS/CFT correspondence in a $D = 5$ bulk, this Hawking–Page phase transition signals the transition from the low temperature, confining phase to the high temperature, de-confining phase of the gauge theory on the boundary [55, 56]. Similar analyses have been done for Gauss–Bonnet–AdS black holes [57–60] using the known analytic solution [7, 8]. The calculations are significantly more complicated and yield a more intricate set of results. Only some parts of the $(b_0, b_1)$ Lovelock parameter space admit stable, large black holes. For still higher curvature Lovelock theories, the static black hole solutions are known only implicitly in terms of a metric function that solves a higher order polynomial equation [9]. In this case, it is both more challenging (or perhaps not possible) to compute the free energy explicitly and also potentially more challenging to analyze any results over the expanded Lovelock parameter space.

However, the process can be simplified. The free energy is given by the temperature $T$ times the Euclidean action $I_E$. Working in the Hamiltonian picture one can show that $I_E = \beta M - S$ where $\beta$ is the Euclidean period [63]. For a smooth Euclidean horizon the period is equal to the inverse temperature and one has $F = M - (\kappa/2\pi)S$. The Smarr formula (38) can now be used to eliminate the mass from the expression of $F$, giving

$$\sum_k b_k(k-1) \Psi^{(k)}.$$ (44)

In the Hawking–Page case only the parameters $b_0$ and $b_1$ are nonzero, and using the relation $b_0 = -2\Lambda r_H^2$, this reduces to

$$F = -\frac{2\Omega_D}{D-3} \frac{r_H^2}{D-2} \left( \kappa + \frac{2\Lambda r_H}{D-1} \right).$$ (45)

In this form we see that there is a positive contribution to the free energy coming from the area, and a negative contribution (for $\Lambda < 0$) coming from the potential $\Theta^{(0)}$. Which one of these terms dominates depends on how the surface gravity $\kappa$ depends on the horizon radius. We have therefore gained some geometrical understanding of the phase transition, namely that the possibility of a thermodynamically stable large black hole comes from the $\Theta^{(0)}$ term in the Smarr relation. In the limits of large and small AdS black holes respectively, it turns out that

$$\kappa \approx \frac{D-3}{2r_H}, \quad b_0 r_H^2 \ll 1, \quad \kappa \approx \frac{b_0 r_H}{2(D-2)}, \quad b_0 r_H^2 \gg 1.$$ (46)

Substituting these into (45) one finds that the free energy $F$ is indeed negative for the large black holes, signaling the phase transition.

This analysis suggests that equation (44) might be used to study the properties of the free energy $F$ for a general Lovelock black hole, even in the absence of fully explicit, analytic solutions. In order to analyze the thermodynamics, one would need to know $F$ as a function of $r_H$ and the Lovelock couplings $b_k$. There are two obstacles to this plan. The surface gravity and the potentials $\Psi^{(k)}$ both need to be determined as functions of $r_H$, in the absence of analytic

---

solutions. We will pursue this goal and also its extension to rotating black holes, in future work.
