Abstract

We present a fully dynamic algorithm for maintaining approximate maximum weight matching in general weighted graphs. The algorithm maintains a matching $M$ whose weight is at least $\frac{1}{8}M^*$ where $M^*$ is the weight of the maximum weight matching. The algorithm achieves an expected amortized $O(\log n \log C)$ time per edge insertion or deletion, where $C$ is the ratio of the weights of the highest weight edge to the smallest weight edge in the given graph. Using a simple randomized scaling technique, we are able to obtain a matching with expected approximation ratio 4.9108.

1 Introduction

Let $G = (V, E)$ be an undirected graph on $n = |V|$ vertices and $m = |E|$ edges. Let there be a weight function $w : E \rightarrow \mathbb{R}^+$ such that $w(e)$, for any $e \in E$, represents the weight of $e$. The weight function for a set of edges $M \subseteq E$ is represented by $w(M)$ and is defined as $\sum_{e \in M} w(e)$.

A subset $M$ of $E$ is a "matching" if no vertex of the graph is incident on more than one edge in $M$. In an unweighted graph, a maximum matching is defined as the maximum cardinality matching (MCM). In an weighted graph, maximum matching is defined as the maximum weight matching (MWM). For any $\alpha > 1$, a matching is called $\alpha$-MWM($\alpha$-MCM) if it is at least $\frac{1}{\alpha}$ factor of MWM(MCM).

A dynamic graph algorithm maintains a data structure associated with some property (connectivity, transitive closure, matching) of a dynamic graph. The aim of a dynamic graph algorithm is to handle updates and answer queries associated with the set of vertices. The updates in the graph can be insertion or deletion of edges ($V$ is assumed to be fixed). The dynamic algorithms which handle only insertions are called incremental algorithms and those

---

*Research supported by the Indo-German Max Planck Center for Computer Science (IMPECS).
that can handle only deletions are called decremental algorithms. An algorithm that can handle both insertions and deletions of edges is called a fully dynamic algorithm. In this paper, we present a fully dynamic algorithm for maintaining an approximate maximum weight matching.

Previous Results

The fastest known algorithm for finding MCM in general graphs is by Micali and Vazirani[9] that runs in $O(m\sqrt{n})$ time. Their algorithm can be used to compute a matching having size $(1 - \epsilon)$ times the size of maximum matching in $O(m/\epsilon)$ time. Mucha and Sankowski[10] designed an algorithm that computes MCM in $O(n^\omega)$, where $\omega < 2.376$ is the exponent of $n$ in the fastest known matrix multiplication algorithm. Relatively, fewer algorithms are known for maintaining matching in a dynamic graph. The first algorithm was designed by Ivkovic and Lloyd[7] with amortized update time $O(n + m)$. Onak and Rubinfeld[11] presented an algorithm that achieves expected amortized polylogarithmic update time and maintains an $\alpha$-approximate MCM where $\alpha$ was claimed to be some large constant but not explicitly calculated. Baswana, Gupta and Sen[1] presented a fully dynamic randomized algorithm for maintaining maximal matching in expected amortized $O(\log n)$ update time. It is well known that a maximal matching is a 2-MCM as well.

For computing maximum weight matching Gabow[6] designed an $O(mn + n^2 \log n)$ time algorithm. Preis[12] designed a $O(m)$ time algorithm for computing a 2-MWM. Drake and Hougardy[2] designed a simpler algorithm for the same problem. Vinkemeier and Hougardy[13] presented an algorithm to compute a matching which is $(2/3 - \epsilon)$ times the size of MWM in $O(m/\epsilon)$ time. Duan, Pettie and Su[3] presented an algorithm to compute a matching which is $(1 - \epsilon)$ times the size of MWM in $O(m\epsilon^{-1} \log \epsilon^{-1})$ time. To the best of our knowledge, there have been no sub-linear algorithm for maintaining MWM or approximate MWM in dynamic graphs.

Preliminaries

Let $M$ be a matching in a graph $G = (V, E)$. A vertex in the graph is called free with respect to $M$ if it is not incident on any edge in $M$. A vertex which is not free is called matched. Similarly, an edge is called matched if it is in $M$ and is called free otherwise. If $(u, v)$ is a matched edge, then $u$ is called be the mate of $v$ and vice versa. A matching $M$ is said to be maximal if no edge can be added to the matching without violating the degree bound of one for a matched vertex. An alternating path is defined as a path in which edges are alternately matched and free, while an augmenting path is an alternating path which begins and ends with free vertices.

Our Results

We present a fully dynamic algorithm that achieves expected amortized $O(\log n \log C)$ update time for maintaining 8-MWM. Here $C$ is the ratio of the weights of the highest weight edge to the smallest weight edge in the given graph. Our algorithm uses, as a subroutine, the algorithm of Baswana, Gupta and Sen[1] for maintaining a maximal matching. We state the main result in [1] formally.
Theorem 1.1. Starting from an empty graph on \( n \) vertices, a maximal matching in the graph can be maintained over any arbitrary sequence of \( t \) insertion and deletion of edges in \( O(t \log n) \) time in expectation and \( O(t \log n + n \log^2 n) \) time with high probability.

Note that for the above algorithm, the matching (random bits) at any time is not known to the adversary\(^1\) for it to choose the updates adaptively.

The idea underlying our algorithm has been inspired by the algorithm of Lotker, Patt-Shamir, and Rosen\(^8\) for maintaining approximate MWM in distributed environment. Their algorithm maintains a 27-MWM in a distributed graph and achieves \( O(1) \) rounds to update the matching upon any edge insertion or deletion.

Overview of our approach

Given that there exist very efficient algorithm \([1]\) for maintaining maximal matching (hence 2-MCM), it is natural to explore if these algorithms can be employed for maintaining approximate MWM. Observe that MCM is a special case of MWM with all edges having the same weight. Since a maximal matching is 2-MCM, it can be observed that a maximal matching is 2-MWM in a graph if all its edges have the same weight. But this observation does not immediately extend to the graphs having non-uniform weights on edges. Let us consider the case when the edge weights are within a range, say, \([\alpha^i, \alpha^{i+1}]\), where \( \alpha > 1 \) is a constant. In such a graph the maximal matching gives a \( 2\alpha \) approximation of the maximum weight matching. So, a maximal matching can be used as an approximation for MWM in a graphs where the ratio of weights of maximum weight edge to the smallest weight edge is bounded by some constant. To exploit this observation, we partition the edges of the graph into levels according to their weight. We select a constant \( \alpha > 1 \) whose value will be fixed later on. Edges at level \( i \) have weights in the range \([\alpha^i, \alpha^{i+1}]\) and the set of edges at level \( i \) is represented by \( E_i \), viz., \( \forall e \in E_i, w(e) \in [\alpha^i, \alpha^{i+1}] \).

Observe that in this scheme of partitioning, any edge is present only at one level. The subgraph at level \( i \) is defined as \( G_i = (V, E_i) \). We maintain a maximal matching \( M_i \) for \( G_i \) using the algorithm of Baswana, Gupta and Sen\([1]\). The maximal matching at each level provides an approximation for the maximum weight matching at that level. However, \( \cup M_i \) is not necessary a matching since a vertex may have multiple edges incident on it from \( \cup M_i \). Let \( H = (V, \cup M_i) \) be the subgraph of \( G \) having only those edges which are part of the maximal matching at some level. Our algorithm maintains a matching in the subgraph \( H \) which is guaranteed to be 8-MWM for the original graph \( G \). The algorithm builds on the algorithm in \([1]\), though the analysis of algorithm for maintaining 8-MWM is not straightforward.

2 Fully Dynamic 8-MWM

Our algorithm maintains a partition of edges according to their levels. A maximal matching \( M_i \) is maintained at each level using the fully dynamic algorithm in \([1]\). While processing any insertion or deletion of an edge, this algorithm will leads to change in the status of edges from being matched to free and vice-versa. This leads to deletion or insertion of edges from/to \( H \). However, since the algorithm \([1]\) achieves expected amortized \( O(\log n) \) time per update, so the expected amortized number of deletions and insertions of edges in \( H \) will also be \( O(\log n) \) only. Our algorithm will maintain a matching \( M \) in the subgraph \( H \) taking advantage of the

---

\(^1\)The oblivious adversarial model is also used in randomized data-structure like universal hashing
hierarchical structure of $H$. Since $H$ is formed by the union of matchings at various levels, a vertex can have at most one neighbor at each level. The matching $M$ is maintained such that for every edge of $H$ which is not in $M$ there must be an edge adjacent to it at a higher level which is in $M$. For an edge $e$, let $Level(e)$ denote its level. In precise words, the algorithm maintains the following invariant after every update.

$$\forall e \in E(H), \text{ either } e \in M \text{ or } e \text{ is adjacent to an edge } e' \in M \text{ such that } Level(e') > Level(e).$$

**Notations**

The algorithm maintains the following information at each stage.

- $M_l$ - A maximal matching at the level $l$.
- $Free(v)$ - A variable which is true if $v$ is free in the matching $M$, and false otherwise.
- $Mate(v)$ - The mate of $v$, if it is not free.
- $Level((u,v))$ or $Level(e)$ - The level at which the edge $e$ or the edge $(u,v)$ is present according to the condition that $\forall e \in G_i, w(e) \in [\alpha^i, \alpha^{i+1}]$.
- $OccupiedLevels$ - The set of levels where there is at least one edge from $H$.
- $L^\text{max}$ - The highest occupied level.
- $L^\text{min}$ - The lowest occupied level.
- $N(v, i)$ - The neighbor of $v$ in $M_i$, if any, and null otherwise.
- $M$ - The matching maintained by our algorithm.

For a better understanding of our fully dynamic algorithm, the following section describes its static version for computing $M$ in the graph $H$.

**Static Algorithm to obtain $M$ from $H$**

| Procedure 2.1: StaticCombine() |
|--------------------------------|
| 1. $M = \emptyset$;         |
| 2. for $i = L^\text{max}$ to $L^\text{min}$ do |
| 3. $M = M \cup M_i$;         |
| 4. for $(u, v) \in M_i$ do   |
| 5. for $j = i - 1$ to $L^\text{min}$ do |
| 6. for $(x, y) \in M_j$ do   |
| 7. if $u = x$ or $u = y$ or $v = x$ or $v = y$ then |
| 8. $M_j = M_j \setminus \{(x, y)\}$; |

4
The static algorithm divides the edges of the graph $G$ into levels and a maximal matching $M_i$ is obtained for each of the levels. Using these maximal matchings we get the graph $H$. Thereafter the level numbers $L^{\text{max}}$ and $L^{\text{min}}$ are computed and the procedure StaticCombine is used.

The procedure StaticCombine starts by picking all the edges in $H$ at the highest level and adds them to the matching $M$. For every edge $(u, v)$ added to the matching $M$, all the edges in the graph $H$ incident on $u$ and $v$ have to be removed from the graph. The same process is repeated for the next lower level. Note that every edge in $H$ is either in the matching $M$ or its neighboring edge at some higher level is in $M$ and thus the invariant is maintained. Observe that the matching $M$ is a maximal matching in $H$ because of the way it is being computed.

**Dynamic Algorithm to maintain $M$**

After each insertion or deletion of any edge, our algorithm maintains a matching $M$ satisfying the invariant described above. Our algorithm processes insertions and deletions of edges in $H$ to update $M$. An addition and deletion of the edges in $H$ is caused due to addition/deletion of an edge in the original graph $G$. We describe some basic procedures first. Then the procedures for handling addition and deletion of edges in $H$ are described and finally the procedures for handling addition and deletion of edges in $G$ are described.

**Procedure 2.2: AddToMatching($u, v$)**

1. $Free(u) = False; Free(v) = False$;
2. $Mate(u) = v; Mate(v) = u$;
3. $M = M \cup \{(u, v)\};$

**Procedure 2.3: DelFromMatching($u, v$)**

1. $Free(u) = True; Free(v) = True$;
2. $M = M \setminus \{(u, v)\};$

The procedure AddToMatching adds an edge to the matching $M$ updating the free and mate fields accordingly. The procedure DelFromMatching deletes an edge from the matching $M$ updating the mate and the free fields correctly. Both of them execute in $O(1)$ time.

The procedure HandleFree takes as an input a vertex $u$ which has become free in $M$ and a level number $lev$ from where it has to start looking for a mate. Note that it follows from the invariant that $u$ does not have any free neighbor at any level above $lev$. The procedure HandleFree proceeds as follows. It searches for a neighbor of $u$ in the decreasing order of levels starting from $lev$. In this process, on reaching a level $l \leq lev$ if it finds a free neighbor of $u$, the corresponding edge is added to the matching $M$ and the procedure stops. Otherwise if some neighbor $v$ is found which already has a mate at some lower level than $l$, then notice that we are violating the invariant as $(u, v)$ does not belong to $M$ and is neighboring to an edge in $M$ at a lower level. So, the edge $(v, Mate(v))$ is removed from the matching $M$, and the edge $(u, v)$ is added to the matching $M$. This change results in a free vertex which is at a lower level and so we proceed recursively to process it. Note that the recursive calls to HandleFree are all with lower level numbers. So, the procedure takes $O(L^{\text{max}} - L^{\text{min}})$ time.
Procedure 2.4: HandleFree(u, lev)

1 for l from lev to $L^{\min}$ do
2 \[ v = N(u, l); \]
3 \[ \text{if } v \text{ is not null then} \]
4 \[ \text{if } v \text{ is free then} \]
5 \[ \text{AddToMatching}(u, v); \]
6 \[ \text{return}; \]
7 \[ \text{else if } \text{Level}((v, \text{Mate}(v))) < l \text{ then} \]
8 \[ v' = \text{Mate}(v); \]
9 \[ \text{DelFromMatching}(v, v'); \]
10 \[ \text{AddToMatching}(u, v); \]
11 \[ \text{HandleFree}(v', \text{Level}((v, v'))); \]
12 \[ \text{return}; \]

The procedure AddEdge handles addition of edges to $H$. Suppose the edge $(u, v)$ is added to $H$. If both $u$ and $v$ are free with respect to $M$, then the edge $(u, v)$ is added to the matching $M$. Otherwise, there must be some edge(s) in $M$ adjacent to $(u, v)$. This follows due to the fact that $M$ is a maximal matching in $H$. If $(u, v)$ is adjacent to a higher level edge in $M$, then nothing is done. If $(u, v)$ is adjacent to some lower level edge(s) in $M$, then notice that the invariant maintained by the algorithm gets violated. Therefore, we remove these lower level edge(s) (adjacent to $(u, v)$) from the matching $M$ and adds the edge $(u, v)$ to the matching. At most 2 vertices can become free due to the addition of this edge to $M$ and we handle them using the procedure HandleFree. If $u'$ was the previous mate of $u$, then the edge $(u, u')$ is removed from $M$. Since $M$ satisfied the invariant before addition of this edge, all the neighboring edges of $u'$ at higher level than $\text{Level}(u, u')$ are matched to a vertex at higher levels. So $u'$ has to start looking for mates from the level of $(u, u')$. The procedure makes a constant number of calls to HandleFree and thus runs in $O(L^{\max} - L^{\min})$ time.

The procedure DeleteEdge does nothing if an unmatched edge from $H$ is deleted. If a matched edge $(u, v)$ is deleted at level $l$, it calls HandleFree for both the end points to restore the invariant in the matching. HandleFree is called with the level $l$ because our invariant implies that all the neighbors of $u$ and $v$ are matched at higher levels. So they cannot find a mate at higher levels. This again takes $O(L^{\max} - L^{\min})$ time.

The function EdgeUpdate handles addition and deletion of an edge in $G$. It finds out the level of the edge and updates the maximal matching at that level using the algorithm of Baswana, Gupta and Sen. It updates the OccupiedLevels set accordingly. This set is required because the values of $L^{\max}$ and $L^{\min}$ are to be maintained. The algorithm can be easily augmented to return the set of edges being added or deleted from the maximal matching in each update. As discussed before, expected amortized $O(\log n)$ edges change their status per update. Our algorithm processes these updates in $H$ as described above. So, overall our algorithm has an expected amortized update time of $O(\log n \cdot (L^{\max} - L^{\min}))$. Let $e^{\max}$ and $e^{\min}$ represent the edges having the maximum and the minimum weight in the graph. Recall that $C = w(e^{\max})/w(e^{\min})$. 

\[ \text{Procedure 2.4: HandleFree}(u, lev) \]

\begin{verbatim}
for l from lev to $L^{\min}$ do
    v = N(u, l);
    if v is not null then
        if v is free then
            AddToMatching(u, v);
            return;
        else if Level((v, Mate(v))) < l then
            v' = Mate(v);
            DelFromMatching(v, v');
            AddToMatching(u, v);
            HandleFree(v', Level((v, v')));
            return;
end for
end procedure
\end{verbatim}

The procedure AddEdge handles addition of edges to $H$. Suppose the edge $(u, v)$ is added to $H$. If both $u$ and $v$ are free with respect to $M$, then the edge $(u, v)$ is added to the matching $M$. Otherwise, there must be some edge(s) in $M$ adjacent to $(u, v)$. This follows due to the fact that $M$ is a maximal matching in $H$. If $(u, v)$ is adjacent to a higher level edge in $M$, then nothing is done. If $(u, v)$ is adjacent to some lower level edge(s) in $M$, then notice that the invariant maintained by the algorithm gets violated. Therefore, we remove these lower level edge(s) (adjacent to $(u, v)$) from the matching $M$ and adds the edge $(u, v)$ to the matching. At most 2 vertices can become free due to the addition of this edge to $M$ and we handle them using the procedure HandleFree. If $u'$ was the previous mate of $u$, then the edge $(u, u')$ is removed from $M$. Since $M$ satisfied the invariant before addition of this edge, all the neighboring edges of $u'$ at higher level than $\text{Level}(u, u')$ are matched to a vertex at higher levels. So $u'$ has to start looking for mates from the level of $(u, u')$. The procedure makes a constant number of calls to HandleFree and thus runs in $O(L^{\max} - L^{\min})$ time.

The procedure DeleteEdge does nothing if an unmatched edge from $H$ is deleted. If a matched edge $(u, v)$ is deleted at level $l$, it calls HandleFree for both the end points to restore the invariant in the matching. HandleFree is called with the level $l$ because our invariant implies that all the neighbors of $u$ and $v$ are matched at higher levels. So they cannot find a mate at higher levels. This again takes $O(L^{\max} - L^{\min})$ time.

The function EdgeUpdate handles addition and deletion of an edge in $G$. It finds out the level of the edge and updates the maximal matching at that level using the algorithm of Baswana, Gupta and Sen. It updates the OccupiedLevels set accordingly. This set is required because the values of $L^{\max}$ and $L^{\min}$ are to be maintained. The algorithm can be easily augmented to return the set of edges being added or deleted from the maximal matching in each update. As discussed before, expected amortized $O(\log n)$ edges change their status per update. Our algorithm processes these updates in $H$ as described above. So, overall our algorithm has an expected amortized update time of $O(\log n \cdot (L^{\max} - L^{\min}))$. Let $e^{\max}$ and $e^{\min}$ represent the edges having the maximum and the minimum weight in the graph. Recall that $C = w(e^{\max})/w(e^{\min})$. 

\[ \text{Procedure 2.4: HandleFree}(u, lev) \]

\begin{verbatim}
for l from lev to $L^{\min}$ do
    v = N(u, l);
    if v is not null then
        if v is free then
            AddToMatching(u, v);
            return;
        else if Level((v, Mate(v))) < l then
            v' = Mate(v);
            DelFromMatching(v, v');
            AddToMatching(u, v);
            HandleFree(v', Level((v, v')));
            return;
end for
end procedure
\end{verbatim}
Procedure 2.5: AddEdge\((u, v)\)

1. \(l = \text{Level}((u, v))\);
2. \(N(u, l) = v\);
3. \(N(v, l) = u\);
4. if \(u\) is free and \(v\) is free then
   - AddToMatching \((u, v)\);
5. else if \(u\) is free and \(v\) is not free then
   - if \(\text{Level}((u, \text{Mate}(u))) < l\) then
     - \(v' = \text{Mate}(v)\);
     - DelFromMatching \((v, v')\);
     - AddToMatching \((u, v)\);
     - HandleFree \((v', \text{Level}((v, v')))\);
6. else if \(u\) is not free and \(v\) is free then
   - if \(\text{Level}((v, \text{Mate}(v))) < l\) then
     - \(u' = \text{Mate}(u)\);
     - DelFromMatching \((u, u')\);
     - AddToMatching \((u, v)\);
     - HandleFree \((u', \text{Level}((u, u')))\);
7. else if \(\text{Level}((v, \text{Mate}(v))) < l\) and \(\text{Level}((u, \text{Mate}(u))) < l\) then
   - \(u' = \text{Mate}(u)\);
   - \(v' = \text{Mate}(v)\);
   - DelFromMatching \((u, u')\);
   - DelFromMatching \((v, v')\);
   - AddToMatching \((u, v)\);
   - HandleFree \((u', \text{Level}((u, u')))\);
   - HandleFree \((v', \text{Level}((v, v')))\);

\[
L_{\text{max}} - L_{\text{min}} < \log_\alpha w(e_{\text{max}}) - \log_\alpha w(e_{\text{min}}) + 1 = O \left( \log \frac{w(e_{\text{max}})}{w(e_{\text{min}})} \right) = O(\log \mathcal{C})
\]

So we can claim that

Claim 2.1. The expected amortized update time of the algorithm per edge insertion or deletion is \(O(\log n \log \mathcal{C})\).

In the next section we analyze the algorithm to prove that the matching \(\mathcal{M}\) maintained by it at each stage is indeed \(8\)-MWM.

2.1 Analysis

To get a good approximation ratio, we bound the weight of \(M^*\) with the weight of \(\mathcal{M}\). We now state a few simple observations which help in understanding the analysis.

Observation 2.1. Since \(M^*\) is a matching, no two edges of \(M^*\) can be incident on the same vertex.
**Procedure 2.6: DeleteEdge(u, v)**

1. \( l = \text{Level}((u, v)) \);
2. \( N(u, l) = \text{null} \);
3. \( N(v, l) = \text{null} \);
4. if \((u, v) \in \mathcal{M}\) then
   5. \( \text{DelFromMatching} (u, v); \)
   6. \( \text{HandleFree} (u, l); \)
   7. \( \text{HandleFree} (v, l); \)

**Procedure 2.7: EdgeUpdate(u, v, type)**

1. \( l = \text{Level}((u, v)) = \lceil \log_\alpha w(u, v) \rceil \);
2. if type is addition and \( M_l \) is \( \emptyset \) then
   3. \( \text{OccupiedLevels} = \text{OccupiedLevels} \cup \{l\}; \)
   4. Update \( L_{\text{max}} \) and \( L_{\text{min}} \);
5. Update \( M_l \) using the algorithm in [1];
6. if type is deletion and \( M_l \) is \( \emptyset \) then
   7. \( \text{OccupiedLevels} = \text{OccupiedLevels} \setminus \{l\}; \)
   8. Update \( L_{\text{max}} \) and \( L_{\text{min}} \);
9. Let \( D \) be the set of edges deleted from \( M_l \) in step 5;
10. Let \( A \) be the set of edges added to \( M_l \) in step 5;
11. for \((x, y) \in D\) do
12. \( \text{DeleteEdge} (x, y); \)
13. for \((x, y) \in A\) do
14. \( \text{AddEdge} (x, y); \)

**Observation 2.2.** For any edge \( e \notin M^* \), there can be at most two edges of \( M^* \) which are adjacent to \( e \), one for each endpoint of \( e \).

To bound the weight of \( M^* \) using the weight of \( \mathcal{M} \), we define a many to one mapping \( \phi : M^* \to \mathcal{M} \). This mapping maps every edge in \( M^* \) to an edge in \( \mathcal{M} \). Using this mapping, we find out all the edges which are mapped to an edge \( e \in \mathcal{M} \) and bound their weight using the weight of \( e \). Let this set be denoted by \( \phi^{-1}(e) \). For an edge \( e^* \in M^* \), the mapping is defined as:

1. If \( e^* \in E(\mathcal{H}) \) and \( e^* \in \mathcal{M} \) then \( \phi(e^*) = e^* \).
2. If \( e^* \in E(\mathcal{H}) \) and \( e^* \notin \mathcal{M} \) then our invariant ensures that \( e^* \) is adjacent to an edge \( e \in \mathcal{M} \) such that \( \text{Level}(e) > \text{Level}(e^*) \). In this case, we define \( \phi(e^*) = e \). If \( e^* \) is adjacent to two matched edges in \( \mathcal{M} \), map \( e^* \) to any one of them. As a rule, if two edges are available for mapping, then we will map \( e^* \) to any one of them.
3. If \( e^* \notin E(\mathcal{H}) \), then consider its level, say \( i \). Since we maintain a maximal matching \( M_i \) at level \( i \), at least one of the end point of \( e^* \) must be present in \( M_i \). Let \( e \in M_i \) be adjacent to \( e^* \). If \( e \in \mathcal{M} \), we define \( \phi(e^*) = e \).
4. If $e^* \notin E(H)$ and the edge $e \in M_i$ adjacent to $e^*$ is not present in $M$ then $e$ must be adjacent to an edge $e' \in M$ such that Level($e'$) > Level($e$). In this case, we define $\phi(e^*) = e'$.

Now that we have defined a many to one mapping, we find out the edges of $M^*$ which are mapped to an edge $e \in M$. An edge which is mapped to $e$ can either be $e$ itself or be adjacent to $e$ or not adjacent to $e$. If an edge of $M^*$, which is mapped to $e \in M$, is $e$ itself or is adjacent to $e$, then it is called a Directly mapped edge. An edge of $M^*$ which is mapped to $e \in M$ and is not adjacent to $e$ is called an Indirectly mapped edge. Let $\phi_D^{-1}(e)$ and $\phi_I^{-1}(e)$ be the set of directly mapped and indirectly mapped edges respectively for an edge $e \in M$. Directly mapped edges are of type 1, 2 and 3 and indirectly mapped edges are of type 4. An edge $e^* \in M^*$ can either be in $E(H)$ or not. If it is in $E(H)$, then it is mapped using type 1 and type 2 mapping else it is mapped using type 3 and type 4 mapping. This implies all the edges in $M^*$ are mapped by $\phi$.

If an edge $e \in M$ has an edge of type 1 directly mapped to it, then $e$ will not have any other edge directly mapped to it. This follows from the definition of a directly mapped edge and Observation 2.1. There can be at most two directly mapped edges of the second type(Observation 2.2). These edges mapped to $e$ are always from a level < Level($e$). There can be at most two directly mapped edges of type 3 also if they are not in $H$ but are adjacent to $e$. By Observation 2.2, there can only be two such edges.

**Claim 2.2.** There can be at most two directly mapped edges to an edge $e \in M$ at any level.

The total weight of the edges directly mapped to $e$ will be maximum when both of them are from the same level as $e$. Assume that $e$ is at level $i$. Summing the weights of the edges which are directly mapped to $e$, we get

$$\sum_{e^* \in \phi_D^{-1}(e)} w(e^*) < 2 \cdot \alpha^{i+1} < 2\alpha w(e)$$  \hspace{1cm} (1)

Indirectly mapped edges can only be of the fourth kind in which the edge is not in $H$, but is adjacent to an edge in $H$, which in turn is adjacent to $e$. By definition, these edges are from a level lower than that of $e$. There can be at most two edges from each level lower than Level($e$) which are in $H$ and are adjacent to $e$(see Figure 1).
Claim 2.3. There can be at most two indirectly mapped edges to an edge $e \in M$ at level $< \text{Level}(e)$.

Note that there can be a large number of edges which are indirectly mapped to $e$. Still we will be able to get a good bound on their total weight. This is because there can be at most two indirectly mapped edges from each level and the weight of edges in the levels decreases geometrically as we go to lower levels.

Assume that $e$ is at level $i$. Summing the weight of edges which are indirectly mapped to $e$, we get

$$\sum_{e^* \in \phi^{-1}_i(e)} w(e^*) < 2 \sum_{j=0}^{i_{\text{min}}} \alpha^{j+1} < \frac{2\alpha^{i+1}}{\alpha - 1} < \frac{2\alpha w(e)}{\alpha - 1}$$

(2)

Thus, the total weight mapped to $e$ is -

$$\sum_{e^* \in \phi^{-1}(e)} w(e^*) = \sum_{e^* \in \phi^{-1}(e)} w(e) + \sum_{e^* \in \phi^{-1}_i(e)} w(e^*) < w(e) \left( \frac{2\alpha}{\alpha - 1} + 2\alpha \right)$$

As reasoned before, an edge in $M^*$ is mapped to some edge in $M$. So summing this over all the edges in $M$, we get

$$\sum_{e \in M} w(e) \left( \frac{2\alpha}{\alpha - 1} + 2\alpha \right) > \sum_{e \in M} \sum_{e^* \in \phi^{-1}(e)} w(e^*) = \sum_{e^* \in M^*} w(e^*)$$

The function $f(\alpha) = \left( \frac{2\alpha}{\alpha - 1} + 2\alpha \right)$ attains its minimum value of 8 at $\alpha = 2$. So, if the value of $\alpha$ is picked to be 2, we get an 8 approximation maximum weight matching algorithm. We can state the following theorem.

Theorem 2.1. There exists a fully dynamic algorithm that maintains 8-MWM for any graph on $n$ vertices in expected amortized $O(\log n \log C)$ time per update.

3 Improvements: Fully Dynamic 4.9108-MWM

We use use the method of geometric rounding (see [4, 5]) to reduce the approximation ratio to 4.9108.

We choose a random number $r$ from $(0, 1]$ and then partition the edges as follows. If an edge $e$ has weight $w(e) \in [\alpha^i, \alpha^{i+1})$, then it belongs to level $i$ where $i \geq 0$. Note that here we assume that the weight of an edge is always greater than $\alpha^i$. This is generally not true but can be handled by initially multiplying the weight of all edges by $\alpha$. From now on we assume that an edge will always belong to some level $i$. Define $w_r(e) = \alpha^{i+r}$ if $e$ belongs to level $i$. The algorithm works on the new weights instead of the original weight of the edge. The working of the algorithm is exactly same as in the previous section.

Lemma 3.1. For an edge $e$, $E_r[w_r(e)/w(e)] = \frac{\alpha^{-1}}{\alpha \log \alpha}$. Also $w(e) \geq w_r(e)$.

Proof. Let $w(e) = \alpha^{i+\delta}$ where $i$ is an integer and $0 < \delta \leq 1$.

So $w_r(e) = \begin{cases} \alpha^{i+r}, & \text{if } r \leq \delta, \\ \alpha^{i+r-1}, & \text{if } r > \delta \end{cases}$
The expected value can be calculated as:

\[ E_r[\frac{w_r(e)}{w(e)}] = \int_0^\delta \frac{\alpha^{r+i}}{\alpha^{i+r}} \, dr + \int_\delta^1 \frac{\alpha^{r+i-1}}{\alpha^{i+r-1}} \, dr \]

\[ = \frac{1}{\alpha^i \ln \alpha} \left( (\alpha^r)_0^\delta + (\alpha^{r-1})_\delta^1 \right) \]

\[ = \frac{1}{\alpha^i \ln \alpha} \left( (\alpha^\delta - 1) + (1 - \alpha^\delta) \right) \]

\[ = \frac{\alpha - 1}{\alpha \ln \alpha} \]

For the second statement of the lemma, if \( e \) is at level \( i \) then \( w(e) \in [\alpha^{i+r}, \alpha^{i+r+1}) \) and \( w_r(e) = \alpha^{i+r} \). So \( w(e) \geq w_r(e) \).

Following the algorithm in the previous section but working on the new weights \( w_r(e) \), we observe that all the edges at level \( i \) have same new weights. The problem we faced in the previous section was that if \( e \in M \) was at level \( i \), then there could be two edges at level \( i \) adjacent to \( e \) in \( M^* \). In the worst case, the weight of \( e \) could be \( 2^r \) and the weight of the edges in \( M^* \) could be \( 2^{i+1} \). The same reasoning also true for the other mapped edges mapped to \( e \) from lower level. This was the reason we got a slightly higher approximation ratio in the previous section. But using the new weights, we see that all the edges at a particular level have same weights.

Using Lemma 3.1 and using linearity of expectation, we get

\[ E_r[\sum_{e^* \in M^*} w_r(e^*)] = \frac{\alpha - 1}{\alpha \ln \alpha} \sum_{e^* \in M^*} w(e) \]

(3)

We now follow the analysis used in the previous section. Let \( e \) be an edge at level \( i \). Let \( \phi^{-1}_D(e) \) be the edges directly mapped to \( e \). Using Claim 2.2, there can at most be two such edges. In the worst case, both of them can be at level \( i \). Summing the weight of edges directly mapped to \( e \), we get

\[ \sum_{e^* \in \phi^{-1}_D(e)} w_r(e^*) = 2\alpha^{i+r} \]

(4)

Let \( \phi^{-1}_I(e) \) be the edges indirectly mapped to \( e \). Using Claim 2.3, there can be at most two indirectly mapped edges at level less than \( i \). Also there can at most be two such edges per level. Summing up the weights of indirectly mapped edges, we get

\[ \sum_{e^* \in \phi^{-1}_I(e)} w_r(e^*) = 2 \sum_{j=i}^{L_{min}} \alpha^{j+r} \]

(5)

Summing up Equation 4 and 5, we get the sum of the edges mapped to \( e \),

\[ \sum_{e^* \in \phi^{-1}(e)} w_r(e^*) = \sum_{e^* \in \phi^{-1}_D(e)} w_r(e^*) + \sum_{e^* \in \phi^{-1}_I(e)} w_r(e^*) = 2 \sum_{j=i}^{L_{min}} \alpha^{j+r} < \frac{2\alpha^{i+r+1}}{\alpha - 1} = \frac{2\alpha w_r(e)}{\alpha - 1} \]

Let \( M_r \) be the matching obtained by our algorithm for a particular \( r \). Again following the analysis in previous section, this implies that
\[
\sum_{e \in M_r} w_r(e) \geq \frac{\alpha - 1}{2\alpha} \sum_{e^* \in M^*} w_r(e^*)
\]

(6)

**Theorem 3.1.** The expected approximation ratio achieved by the algorithm is \( \frac{2\alpha^2 \ln \alpha}{(\alpha - 1)^2} \). The ratio is minimized when \( \alpha \approx 3.512 \) and the approximation ratio obtained is \( \approx 4.9108 \).

**Proof.** Using Equation 6 and taking expectation on both sides we get,
\[
E_r[\sum_{e \in M_r} w_r(e)] \geq \frac{\alpha - 1}{2\alpha} E_r[\sum_{e^* \in M^*} w_r(e^*)]
\]
\[
\geq \frac{(\alpha - 1)^2}{2\alpha^2 \ln \alpha} \sum_{e^* \in M^*} w(e^*) \quad \text{Using Equation 3}
\]

Using Lemma 3.1, \( w(e) \geq w_r(e) \) for each edge \( e \) and we get
\[
E_r[\sum_{e \in M_r} w(e)] \geq \frac{(\alpha - 1)^2}{2\alpha^2 \ln \alpha} \sum_{e^* \in M^*} w(e^*)
\]
This implies that the expected approximation ratio obtained by our algorithm is \( \frac{2\alpha^2 \ln \alpha}{(\alpha - 1)^2} \). It achieves its minimum value when \( \alpha \approx 3.512 \) and the minimum expected approximation ratio obtained is \( \approx 4.9108 \).

**Theorem 3.2.** There exists a fully dynamic algorithm that maintains expected 4.9108-MWM for any graph on \( n \) vertices in expected amortized \( O(\log n \log C) \) time per update.

4 Conclusion

We presented a fully dynamic algorithms for maintaining matching of large size or weight in graphs. The algorithm maintains a 8-MWM with expected \( O(\log n \log C) \) amortized update time. Using a simple randomized scaling technique, we are able to obtain an expected 4.9108-MWM with the same update time. The algorithm for maintaining 4.9108-MWM is the first fully dynamic algorithm for maintaining approximate maximum weight matching.
