Abstract. Graph polynomials which are definable in Monadic Second Order Logic (MSOL) on the vocabulary of graphs are Fixed-Parameter Tractable (FPT) with respect to clique-width. In contrast, graph polynomials which are definable in MSOL on the vocabulary of hypergraphs are fixed-parameter tractable with respect to tree-width, but not necessarily with respect to clique-width. No algorithmic meta-theorem is known for the computation of graph polynomials definable in MSOL on the vocabulary of hypergraphs with respect to clique-width. We define an infinite class of such graph polynomials extending the class of graph polynomials definable in MSOL on the vocabulary of graphs and prove that they are Fixed-Parameter Polynomial Time (FPPT) computable, i.e. that they can be computed in time $O(n^{f(k)})$, where $n$ is the number of vertices and $k$ is the clique-width.

1 Introduction

In recent years there has been growing interest in graph polynomials, functions from graphs to polynomial rings which are invariant under isomorphism. Graph polynomials encode information about the graphs in a compact way in their evaluations, coefficients, degree and roots. Therefore, efficient computation of graph polynomials has received considerable attention in the literature. Since most graph polynomials which naturally arise are $\sharp P$-hard to compute (see e.g. [10, 20, 11]), a natural perspective under which to study the complexity of graph polynomials is that of parameterized complexity.

Parameterized complexity is a successful approach to tackling NP-hard problems [18, 20], by measuring complexity with respect to an additional parameter of the input; we will be interested in the parameters tree-width and clique-width. A

computational problem is **fixed-parameter tractable** (FPT) with respect to a parameter $k$ if it can be solved in time $f(k) \cdot p(n)$, where $f$ is a computable function of $k$, $n$ is the size of the input, and $p(n)$ is a polynomial in $n$. Many NP-hard problems are fixed parameter tractable for an appropriate choice of parameter, see [20] for many examples. Every problem in the infinite class of decision problems definable in *Monadic Second Order Logic* (MSOL) is fixed-parameter tractable with respect to tree-width by Courcelle’s Theorem [13,9,14] (though the result originally was not phrased in terms of parameterized complexity).

The computation problem we consider for a graph polynomial $P(G; x_1, \ldots, x_r)$ is the following:

**P – Coefficients**

**Instance:** A graph $G$

**Problem:** Compute the coefficients $a_{i_1, \ldots, i_r}$ of the monomials $x_1^{i_1} \cdots x_r^{i_r}$.

For graph polynomials, a parameterized complexity theory with respect to tree-width has been developed. Here, the goal is to compute, given an input graph, the table of coefficients of the graph polynomial. The Tutte polynomial has been shown to be fixed-parameter tractable [38,8,35] used a logical method to study the parameterized complexity of an infinite class of graph polynomials, including the Tutte polynomial, the matching polynomial, the independence polynomial and the Ising polynomial. [35] showed that the class of graph polynomials definable in MSOL in the vocabulary of hypergraphs [3] is fixed-parameter tractable. This class contains the vast majority of graph polynomials which are of interest in the literature.

Going beyond tree-width to clique-width the situation becomes more complicated. [15] studied the class of graph polynomials definable in MSOL in the vocabulary of graphs. They proved that every graph polynomial in this class is fixed-parameter tractable with respect to clique-width. However, this class of graph polynomials does not contain important examples such as the chromatic polynomial, the Tutte polynomial and the matching polynomial. In fact, [21] proved that the chromatic polynomial and the Tutte polynomial are not fixed-parameter tractable with respect to clique-width (under the widely believed complexity-theoretic assumption that FPT $\neq W[1]$). [27] proved that the chromatic polynomial and the matching polynomial are **fixed-parameter polynomial time** computable with respect to clique-width, meaning that they can be computed in time $n^{f(cw(G))}$, where $n$ is the size of the graph, $cw(G)$ is the clique-width of the graph and $f$ is a computable function. [28] proved an analogous result for the Ising polynomial. The main result of this paper is a meta-theorem generalizing the fixed-parameter polynomial time computability of the chromatic polynomial, the matching polynomial and the Ising polynomial to an infinite family of graph polynomials definable in MSOL analogous to [15].

---

3 In [14], MSOL in the vocabulary of hypergraphs is denoted $MS_2$, while MSOL in the vocabulary of graphs is denoted $MS_1$. 

---

2
**Theorem 1** Let \( P \) be an MSOL-Ising polynomial. \( P \) is fixed-parameter polynomial time computable with respect to clique-width.

The class of MSOL-Ising polynomials is defined in Section 2.1.

2 Preliminaries

Let \([k] = \{1, \ldots, k\}\). Let \( \tau_G \) be the vocabulary of graphs \( \tau_G = (E) \) consisting of a single binary relation symbol \( E \). A \( k \)-graph is a structure \((V, E, R_1, \ldots, R_k)\) which consists of a simple graph \( G = (V, E) \) together with a partition \( R_1, \ldots, R_k \) of \( V \). Let \( \tau^k_G \) denote the vocabulary of \( k \)-graphs \( \tau^k_G = \langle E, R_1, \ldots, R_k \rangle \) extending \( \tau_G \) with unary relation symbols \( R_1, \ldots, R_k \).

The class \( CW(k) \) of \( k \)-graphs of clique-width at most \( k \) is defined inductively. Singletons belong to \( CW(k) \), and \( CW(k) \) is closed under disjoint union \( \sqcup \) and two other operations, \( \rho_i \rightarrow_j \) and \( \eta_{i,j} \), to be defined next. For any \( i, j \in [k] \), \( \rho_i \rightarrow_j(G, \bar{R}) \) is obtained by relabeling any vertex with label \( R_i \) to label \( R_j \). For any \( i, j \in [k] \), \( \eta_{i,j}(G, \bar{R}) \) is obtained by adding all possible edges \((u, v)\) between members of \( R_i \) and members of \( R_j \). The clique-width of a graph \( G \) is the minimal \( k \) such that there exists a labeling \( \bar{R} \) for which \((G, \bar{R}) \) belongs to \( CW(k) \). We denote the clique-width of \( G \) by \( cw(G) \). The clique-width operations \( \rho_i \rightarrow_j \) and \( \eta_{i,j} \) are well-defined for \( k \)-graphs. The definitions of these operations extend naturally to structures \((V, E, S)\) which expand \( k \)-graphs with \( S \subseteq V \).

A \( k \)-expression is a term \( t \) which consists of singletons, disjoint unions \( \sqcup \), relabeling \( \rho_i \rightarrow_j \) and edge creations \( \eta_{i,j} \), which witnesses that the graph \( val(t) \) obtained by performing the operations on the singletons is of clique-width at most \( k \). Every graph of tree-width at most \( k \) is of clique-width at most \( 2k^2 + 1 \), cf. [10]. While computing the clique-width of a graph is NP-hard, S. Oum and P. Seymour showed that given a graph of clique-width \( k \), finding a \((2^{3k^2 + 2} - 1)\)-expression is fixed parameter tractable with clique-width as parameter, cf. [25,39].

For a formula \( \varphi \), let \( qr(\varphi) \) denote the quantifier rank of \( \varphi \). For every \( q \in \mathbb{N} \) and vocabulary \( \tau \), we denote by MSOL\(^q\)(\( \tau \)) the set of MSOL-formulas on the vocabulary \( \tau \) which have quantifier rank at most \( q \). For two \( \tau \)-structures \( A \) and \( B \), we write \( A \equiv^q B \) to denote that \( A \) and \( B \) agree on all the sentences of quantifier rank \( q \).

**Definition 1** (Smooth operation). An \( \ell \)-ary operation \( Op \) on \( \tau \)-structures is called smooth if for all \( q \in \mathbb{N} \), whenever \( A_j \equiv^q B_j \) for all \( 1 \leq j \leq \ell \), we have

\[
Op(A_1, \ldots, A_\ell) \equiv^q Op(B_1, \ldots, B_\ell).
\]

Smoothness of the clique-width operations is an important technical tool for us:

**Theorem 2** (Smoothness, cf. [34])
1. For every vocabulary \( \tau \), the disjoint union \( \sqcup \) of two \( \tau \)-structures is smooth.

2. For every \( 1 \leq i \neq j \leq k \), \( \rho_{i \rightarrow j} \) and \( \eta_{i,j} \) are smooth.

It is convenient to reformulate Theorem 2 in terms of Hintikka sentences (see [19]):

**Proposition 3 (Hintikka sentences)** Let \( \tau \) be a vocabulary. For every \( q \in \mathbb{N} \) there is a finite set

\[
H_q^\tau = \{ h_1, \ldots, h_\alpha \}
\]

of MSOL\(^q(\tau)\)-sentences such that

1. Every \( h \in H_q^\tau \) has a finite model.
2. The conjunction \( h_1 \land h_2 \) of any two distinct \( h_1, h_2 \in H_q^\tau \) is unsatisfiable.
3. Every MSOL\(^q(\tau)\)-sentence \( \theta \) is equivalent to exactly one finite disjunction of sentences in \( H_q^\tau \).
4. Every \( \tau \)-structure \( A \) satisfies a unique member \( h_\alpha \in H_q^\tau \) of \( H_q^\tau \).

In order to simplify notation we omit the subscript \( \tau \) in \( h_\alpha \) when \( \tau \) is clear from the context.

Let \( \tau_S \) be the vocabulary consisting of the binary relation symbol \( E \) and the unary relation symbol \( S \). Let \( \tau_S,k \) extend \( \tau_S \) with the unary relation symbols \( R_1, \ldots, R_k \). From Theorem 2 and Proposition 3 we get:

**Theorem 4** For every \( k \in \mathbb{N}^+ \):

1. There is \( F_{\sqcup} : H_q^{\tau_S,k} \times H_q^{\tau_S,k} \rightarrow H_q^{\tau_S,k} \) such that, for every \( M_1 \) and \( M_2 \), \( F_{\sqcup}(hin^q(M_1), hin^q(M_2)) = hin^q(M_1 \sqcup M_2) \).
2. For every unary operation \( op \in \{ \rho_{p \rightarrow q}, \eta_{p,q} : p, q \in [k] \} \), there is \( F_{op} : H_q^{\tau_S,k} \rightarrow H_q^{\tau_S,k} \) such that, for every \( M \), \( F_{op}(hin^q(M)) = hin^q(op(M_1 \sqcup M_2)) \).

### 2.1 MSOL-Ising polynomials

For every \( t \in \mathbb{N}^+ \), let \( \tau_t = \tau \cup \{ S_1, \ldots, S_t \} \), where \( S_1, \ldots, S_t \) are new unary relation symbols.

**Definition 5 (MSOL-Ising polynomials)** For every \( t \in \mathbb{N}^+ \), \( \theta \in \text{MSOL}(\tau_t) \) and \( G = (V, E) \) we define \( P_{t,\theta}(G; X, Y) \) as follows:

\[
P_{t,\theta}(G; X, Y) = \sum_{S_1 \sqcup \cdots \sqcup S_t = V} \prod_{i=1}^t X_{|S_i|}^{S_i} \prod_{1 \leq i_1 \leq i_2 \leq t} Y_{i_1,i_2}^{(S_{i_1} \times S_{i_2}) \cap E}
\]

\( P_{t,\theta} \) is the sum over partitions \( S_1, \ldots, S_t \) of \( V \) such that \( (G, S_1, \ldots, S_t) \) satisfies \( \theta \) of the monomials obtained as the product of \( X_{i}^{S_i} \) for all \( 1 \leq i \leq t \) and \( Y_{i_1,i_2}^{(S_{i_1} \times S_{i_2}) \cap E} \) for all \( 1 \leq i_1 < i_2 \leq t \).
Example 1 (Ising polynomial). The trivariate Ising polynomial $Z(G; x, y, z)$ is a partition function of the Ising model from statistical mechanics used to study phase transitions in physical systems in the case of constant energies and external field. $Z(G; x, y, z)$ is given by

$$Z(G; x, y, z) = \sum_{S \subseteq V} x^{|S|} y^{|\partial S|} z^{|E(S)|}$$

where $\partial S$ denotes the set of edges between $S$ and $V \setminus S$, and $E(S)$ denotes the set of edges inside $S$. $Z(G; x, y, z)$ was the focus of study in terms of hardness of approximation in [24] and in terms of hardness of computation under the exponential time hypothesis was studied in [28]. [28] also showed that $Z(G; x, y, z)$ is fixed-parameter polynomial time computable.

$Z(G; x, y, z)$ generalizes a bivariate Ising polynomial, which was studied for its combinatorial properties in [7]. [7] showed that $Z(G; x, y, z)$ contains the matching polynomial, the van der Waerden polynomial, the cut polynomial, and, on regular graphs, the independence polynomial and clique polynomial.

Example 2 (Independence-Ising polynomial). The independence-Ising polynomial $I_{Is}(G; x, y)$ is given by

$$I_{Is}(G; x, y) = \sum_{S \subseteq V} x^{|S|} y^{|\partial S|}$$

$s$ is an independent set

$I_{Is}(G; x, y)$ contains the independence polynomial as the evaluation $I(G; x) = I_{Is}(G; x, 1)$. See the survey [33] for a bibliography on the independence polynomial. The evaluation $y = 0$ is $I_{Is}(G; x, 0) = (1 + x)^{iso(G)}$, where $iso(G)$ is the number of isolated vertices in $G$. $I_{Is}(G; x, y)$ is an evaluation of an MSOL-Ising polynomial:

$$I_{Is}(G; x, y) = P_{2,\theta_1}(G; 1, x, 1, y, 1)$$

where $\theta_1(S) = \forall x \forall y \ (E(x, y) \rightarrow (\neg S_2(x) \lor \neg S_2(y)))$.

Example 3 (Dominating-Ising polynomial). The Dominating-Ising polynomial is given by $D_{Is}(G; x, y, z)$

$$D_{Is}(G; x, y, z) = \sum_{S \subseteq V} x^{|S|} y^{|\partial S|} z^{|E(S)|}$$

$s$ is a dominating set

where $\partial S$ denotes the set of edges between $S$ and $V \setminus S$. $D_{Is}(G; x, y, z)$ contains the domination polynomial $D(G; x)$. $D(G; x)$ is the generating function of its
dominating sets and we have \( D_{1s}(G; x, 1, 1) = D(G; x) \). The domination polynomial first studied in [10] and it and its variations have received considerable attention in the literature in the last few years, see e.g. [11,12,13,13,14,15,16,17]. Previous research focused on combinatorial properties such as recurrence relations and location of roots. Hardness of computation was addressed in [31].

\[ D_{1s}(G; x, y, z) \] encodes the degrees of the vertices of \( G \): the number of vertices with degree \( j \) is the coefficient of \( x^j y^j \) in \( D_{1s}(G; x, y, z) \). \( D_{1s}(G; x, y, z) \) is an MSOL-Ising polynomial given by

\[ P_{2, \theta_D}(G; x, 1, z, y, 1) \]

where

\[ \theta_D = \forall x (S_1(x) \lor \exists y (S_1(y) \land E(x, y))) . \]

### 2.2 MSOL-Ising polynomials vs MSOL-polynomials

Two classes of graph polynomials which have received attention in the literature are:

1. MSOL-polynomials on the vocabulary of graphs, and
2. MSOL-polynomials on the vocabulary of hypergraphs.

See e.g. [29] for the exact definitions. The former class contains graph polynomials such as the independence polynomial and the domination polynomial. The latter class contains graph polynomials such as the Tutte polynomial and the matching polynomial. Every graph polynomial which is MSOL-definable on the vocabulary of graphs is also MSOL-definable on the vocabulary of hypergraphs.

The class of MSOL-Ising polynomials strictly contains the MSOL-polynomials on graphs, see Fig. 1. The containment is by definition. For the strictness, we use the fact that by definition the maximal degree of any indeterminate in an MSOL-polynomial on graphs grows at most linearly in the number of vertices, while the maximal degree of \( y \) in the Ising polynomial \( Z(K_{n,n}; x, y, z) \) of the complete bipartite graph \( K_{n,n} \) equals \( n^2 \).

Every MSOL-Ising polynomial \( P_{t, \theta} \) is an MSOL-polynomial on the vocabulary of hypergraphs, given e.g. by

\[
\sum_s \sum_B \prod_{i=1}^t X_i^{S_i} \prod_{1 \leq i_1 \leq i_2 \leq t} Y_{i_1, i_2}^{B_{i_1, i_2}}
\]

where the summation over \( \tilde{S} \) is exactly as in Definition 5 and the summation over \( \tilde{B} \) is over tuples \( \tilde{B} = (B_{i_1, i_2} : 1 \leq i_1 \leq i_2 \leq t) \) of subsets of the edge set of \( G \) satisfying \( \Lambda_{i_1, i_2} \psi_{i_1, i_2} \), where

\[ \psi_{i_1, i_2} = \forall x \forall y (B_{i_1, i_2}(x, y) \leftrightarrow (E(x, y) \land (S_{i_1}(x) \land S_{i_2}(y) \lor S_{i_1}(y) \land S_{i_2}(x)))) \]

We use the fact that \( S_1, \ldots, S_t \) is a partition of the set of vertices is definable in MSOL.
3 Main result

We are now ready to state the main theorem and prove a representative case of it.

**Theorem 6 (Main theorem)** For every MSOL-Ising polynomial $P_{t, \theta}$ there is a function $f(k, \theta, t)$ such that $P_{t, \theta}(G; \bar{X}, \bar{Y}, \bar{Z})$ is computable on graphs $G$ of size $n$ and of clique-width at most $k$ in running time $O(n^{f(k, \theta, t)})$.

We prove the theorem for graph polynomials of the form

$$Q_{\theta}(G; X, Y) = \sum_{S: G = \theta(S)} X^{[S]} Y^{[\partial S]}$$

for every $\theta \in \text{MSOL}(\tau_S)$. The summation in $Q_{\theta}$ is over subsets $S$ of the vertex set of $G$. The graph polynomials $Q_{\theta}$ are a notational variation of $P_{t, \theta}$ with $t = 2$, $X_2 = 1$ and $Y_1 = Y_2 = 1$; for every $\theta \in \text{MSOL}(\tau_2)$, $P_{2, \theta}(G; X, 1, 1, Y, 1) = Q_{\theta'}(G; X, Y)$, where $\theta'$ is obtained from $\theta$ by substituting $S_1$ with $S$ and $S_2$ with $\neg S$. The proof for the general case is in similar spirit.

For every $q \in \mathbb{N}$ there is a finite set $\mathfrak{A}_q$ of MSOL$(\tau_{S,k})$-Ising polynomials such that, for every formula $\theta \in \text{MSOL}^q(\tau_S)$, $Q_{\theta}$ is a sum of members of $\mathfrak{A}_q$ (see below). The algorithm computes the values of the members of $\mathfrak{A}_q$ on $G$ by dynamic programming over the parse term of $G$, and using those values, the value of $Q_{\theta}$ on $G$.

More precisely, for every $\beta \in \mathcal{H}_{\tau_{S,k}}$, let

$$A_{\beta}(G; \bar{x}, \bar{y}) = \sum_{S: G = \beta(S)} \prod_{1 \leq c \leq k} x_c^{[S \cap R_c]} \prod_{1 \leq c_1, c_2 \leq k} y_{c_1, c_2}^{[R_{c_1} \cap S \times (R_{c_2} \setminus S)]}$$
and let

\[ A_q = \{ A_\beta : \beta \in \mathcal{H}_{q,s,k} \}. \]

Every \( \theta \in \text{MSOL}^q(\tau_S) \) also belongs to \( \text{MSOL}^q(\tau_{S,k}) \), and hence there exists by Proposition 3 a set \( \mathcal{H} \subseteq \mathcal{H}_{q,s,k} \) such that

\[ \theta \equiv \bigvee_{h \in \mathcal{H}} h \]

Hence,

\[ Q_\theta(G; X, Y) = \sum_{h \in \mathcal{H}} A_h(G; \bar{x}, \bar{y}) \tag{1} \]

setting \( x_c = X \) and \( y_{c_1,c_2} = Y \) for all \( 1 \leq c, c_1, c_2 \leq k \).

For tuples \( \bar{b} = ((b_c : c \in [k]), (b_{c_1,c_2} : c_1, c_2 \in [k])) \in [n]^k \times [n]^{k^2} \), let \( \text{coeff}_G^\beta(\bar{b}) \in \mathbb{N} \) be the coefficient of

\[ \prod_c x_c^{b_c} \prod_{c_1,c_2} y_{c_1,c_2}^{b_{c_1,c_2}} \]

in \( A_\beta(G; \bar{x}, \bar{y}) \).

Algorithm.

Given a \( k \)-graph \( G \), the algorithm first computes a parse tree \( t \) as in [25,39]. The algorithm then computes \( A_\beta(G; \bar{x}, \bar{y}) \) for all \( \beta \in \mathcal{H}_{q,s,k} \) by induction over \( t \):

1. If \( G \) is a graph of size 1, then \( A_\beta(G) \) is computed directly.

2. Let \( G \) be the disjoint union of \( H_A \) and \( H_B \). We compute \( \text{coeff}_G^\beta(\bar{b}) \) for every \( \beta \in \mathcal{H}_{q,s,k} \) and \( \bar{b} \in [n]^k \times [n]^{k^2} \) as follows:

\[ \text{coeff}_G^\beta(\bar{b}) = \sum_{h_1,h_2 : F(h_1,h_2) = \beta} \sum_{d+\bar{c} = \bar{b}} \text{coeff}_{H_A}^H(h) \text{coeff}_{H_B}^H(\bar{c}) \]

3. Let \( G = \rho_{p \rightarrow q}(H) \). We compute \( \text{coeff}_G^\beta(\bar{b}) \) for every \( \beta \in \mathcal{H}_{q,s,k} \) and \( \bar{b} \in [n]^k \times [n]^{k^2} \) as follows:

\[ \text{coeff}_G^\beta(\bar{b}) = \sum_{h : F_{p \rightarrow q}(h) = \beta} \sum_{d} \text{coeff}_H^H(h \bar{d}) \]

where the inner summation is over \( \bar{d} \) such that

\[ b_c = \begin{cases} d_c & c \notin \{p, q\} \\ d_p + d_q & c = q \\ 0 & c = p \end{cases} \]
and

\[
\begin{cases}
\quad d_{c_1,c_2} & c_1, c_2 \notin \{p, q\} \\
\quad 0 & p \in \{c_1, c_2\} \\
\quad d_{q,q} + d_{p,p} + d_{p,q} + d_{q,p} & c_1 = c_2 = q \\
\quad d_{q,c_2} + d_{p,c_2} & c_1 = q, c_2 \notin \{q, p\} \\
\quad d_{c_1,q} + d_{c_1,p} & c_2 = q, c_1 \notin \{q, p\}
\end{cases}
\]

4. Let \( G = n_p q(H) \) with \( p \neq q \). Let \( n_G \) be the number of vertices in \( G \). We compute \( \text{coeff}_\beta^G(\tilde{b}) \) for every \( \beta \in H^k_{\eta} \) and \( \tilde{b} \in [n]^k \times [n]^k \) as follows:

\[
\text{coeff}_\beta^G(\tilde{b}) = \sum_{h:F_{n_p,q}(h)=\beta} \sum_{\tilde{d}} \text{coeff}_h^H(\tilde{d})
\]

where the summation is over \( \tilde{d} \) such that \( b_c = d_c \) and

\[
b_{c_1,c_2} = \begin{cases}
\quad d_{c_1,c_2} & \{c_1, c_2\} \neq \{p, q\} \\
\quad d_p(n_G - d_q) & c_1 = p, c_2 = q \\
\quad d_q(n_G - d_p) & c_1 = q, c_2 = p
\end{cases}
\]

Finally, the algorithm computes \( Q_\theta \) as the sum from Eq. (1).

### 3.1 Runtime

The main observations for the runtime analysis are:

- The size of the set \( \mathcal{H}^k_{\eta} \) of Hintikka sentences is a function of \( k \) but does not depend on \( n \). Let \( s^k_{\eta} = |\mathcal{H}^k_{\eta}| \).
- By definition of \( A_\beta \), for a monomial \( \prod_{1 \leq c \leq k} x_c^{i_c} \prod_{1 \leq c_1, c_2 \leq k} y_{c_1,c_2}^{j_{c_1,c_2}} \) to have a non-zero coefficient, it must hold that \( i_c \leq n \) and \( j_{c_1,c_2} \leq \binom{2}{2} \), since \( i_c \) and \( j_{c_1,c_2} \) are sizes of sets of vertices and sets of edges, respectively.
- The coefficient of any non-monomial of \( A_\beta \) is at most \( 2^n \).
- The parse tree guaranteed in [25][39] is of size \( O(n^c f_1(k)) \) for suitable \( f_1 \) and \( c \).

The algorithm performs a single operation for every node of the parse tree.

**Singletons:** the coefficients of every \( A_\beta \in \mathfrak{A}_\eta \) for a singleton \( k \)-graph can be computed in time \( O(k) \), which can be bounded by \( O(n^k) \).

**Disjoint union, recoloring and edge additions:** the algorithm sums over (1) \( h \in \mathcal{H}^k_{\eta} \) or pairs \((h_1, h_2) \in \left( \mathcal{H}^k_{\eta} \right)^2 \) and (2) over \( \tilde{d} \in [n]^k \times [n]^k \) or pairs \((\tilde{d}, \overline{e}) \in ([n]^k \times [n]^k)^2 \), then (3) performs a fixed number of arithmetic operations on numbers which can be written in \( O(n) \) space.

Each node in the parse tree requires time at most

\[
O\left(n^k (s^k_{\eta})^2 \left([n]^k \times [n]^k\right)^2\right).
\]

Since the size of the parse tree is \( O(n^c f_1(k)) \), the algorithm runs in fixed-parameter polynomial time.
4 Conclusion

We have defined a new class of graph polynomials, the MSOL-Ising polynomials, extending the MSOL-polynomials on the vocabulary of graphs and have shown that every MSOL-Ising polynomial can be computed in fixed-parameter polynomial time. This result raises the question of which graph polynomials are MSOL-Ising polynomials. In previous work [23,36,29] we have developed a method based on connection matrices to show that graph polynomials are not definable in MSOL over either the vocabulary of graphs or hypergraphs.

Problem 1. How can connection matrices be used to show that graph polynomials are not MSOL-Ising polynomials?

The Tutte polynomial does not seem to be an MSOL-Ising polynomial. [22] proved that the Tutte polynomial can be computed in subexponential time for graphs of bounded clique-width. More precisely, the time bound in [22] is of the form $\exp(n^{1-f(cw(G))})$, where $0 < f(i) < 1$ for all $i \in \mathbb{N}$.

Problem 2. Is there a natural infinite class of graph polynomials definable in MSOL which includes the Tutte polynomial such that membership in this class implies fixed parameter subexponential time computability with respect to clique-width (i.e., that the graph polynomial is computable in $\exp(n^{1-g(cw(G))})$ time for some function $g$ satisfying $0 < g(i) < 1$ for all $i \in \mathbb{N}$)?
