Abstract. The objective of this study was to determine the effects of aging period on shear force values and activities of calpain/calpastatin enzymes of the longissimus dorsi (LD) muscle from rusa deer (Cervus timorensis). The shear force values were measured with instron materials testing machine. Results showed that postmortem storage influenced meat tenderness with a highly significant reduction of shear force value from 9.01±0.83 kg/cm² at day 1 to 4.34±0.10 kg/cm² at day 21 (P<0.01). Determination of the enzyme activities indicated that the µ-calpain activity decreased significantly from 1.50±0.42 to 0.19±0.28 units/g of meat (P<0.01), whereas m-calpain activity (22.88±9.64 to 16.95±8.34 units/g of meat) and calpastatin activity (9.93±2.37 to 6.82±2.96 units/g of meat) slightly decreased (P>0.05). Shear force values were significant correlated with higher levels of µ-calpain (r=0.915) and m-calpain (r=0.758), respectively. However, the values were not significant related to the calpastatin activity (r=0.462). Therefore, this study confirmed that in the case of rusa deer, µ-calpain is a key factor controlling postmortem meat tenderness compared to m-calpain and calpastatin. The results suggested that storage of the rusa deer meat for 7 days is enough to achieve aging of the LD muscle, which may help to reduce the cost of meat production.

Keywords: postmortem storage, shear force, calpain/calpastatin activity, rusa deer.

1 Introduction

Rusa deer (cervus timorensis) have been an alternative farm animal. Most important commercial product in the tropical countries is deer meat [1]. Deer meat contents a high level in protein and minerals, but low-fat content and cholesterol [2-3]. In Thailand, consumption of deer meat is increased. Improvement of farm management, feeding and reproduction were studied, but improvement of the deer meat quality is uninformative. In meat quality traits, tenderness is commonly known as one of the most important traits for consumer. Tenderness is controlled by the level of proteolysis of the endogenous proteolytic enzymes of the calpain protease system including calpains and calpastatin [4-7]. The calpains are cysteine peptidases present in different forms and tissues while the calpastatin acts as a specific inhibitor. Activities of the calpains is mainly controlled by Ca²⁺, phospholipids and their specific inhibitor. Several studies reported that the calpain concentration in the muscle and the calpain/calpastatin ratio could be used as a good predictor of ultimate tenderness. The influences of the calpain enzyme system on meat tenderness can be expected to apply in deer meat [4-5, 8]. However, studies on the meat tenderization of rusa deer has been limited in Thailand. Here, the shear force values, and the µ-calpain, m-calpain and calpastatin in the longissimus dorsi muscle of the rusa deer associated with postmortem storage were revealed.

2 Material and Methods

2.1 Samples Preparation

The rusa deer meat was raised by Deer Co-operative of Thailand LTD., Kasetsart University, Kamphaeng Saen Campus Thailand. Ten female rusa deer (2 to 3 years of age, live weight 40 to 60 kg) were slaughtered and longissimus dorsal (LD) muscle were obtained within 45 min after exsanguination. The LD muscles were removed from the left side of the carcass, wrapped in plastic wrap, placed in cooling pack and transported immediately to meat science laboratory at Meat Technology Research Network Center, King Mongkut’s Institute of Technology Ladkrabang, Bangkok, Thailand. The LD muscles were trimmed free from external fat and connective tissue. After that, LD muscles were divided into six pieces and vacuum packed. All was aged at 4 °C for 1, 3, 5, 7, 14 and 21 days postmortem.

2.2 Shear Force Values Measurement

The LD muscles were chopped into 2.5 cm thick, were boiled on water bath at 80°C until reached an internal
temperature of 70 to 75°C. The sample was cooled by rinsing with water until the internal temperature decreased to 25°C. They were chopped into 1 cm in diameter parallel to the longitudinal orientation of the muscle fibers. The shear force values were measured by instron materials testing machine (Instron Model 1011, USA). The average maximum force (kg/cm²) to cut across the fibers. Ten pieces was used for each sample [9].

2.3 Calpain/Calpastatin Activity Analysis

Ten grams of LD muscles was homogenized in 30 mL of extraction buffer (100 mM Tris/HCl, pH 8.3, 10 mM EDTA, 0.05% [vol/vol] MCE, 100 mg/L ovomucoid, 2 mM phenylmethylsulfonyl fluoride (PMSF), 6 mg/L leupeptin, 4°C) at 30 second cooling period between bursts. The homogenate was centrifuged at 30,000×g max for 1 hour at 4°C and filtered through glass wool. After clarification, the sample were dialyzed against 25 volumes of dialysis buffer (40 mM Tris/HCl, pH 7.35, 5 mM EDTA, 0.05% [vol/vol] MCE) for 24 hours at 4°C and centrifuged 30,000×g max for 30 minutes at 4°C. The extract applied to a DEAE-Sephacel by gravity. After loading, the column was washed with 5 column volumes of elution buffer (40 mM Tris/HCl, pH 7.35, 0.5 mM EDTA, 0.05% [v/v] MCE) to removed unbound proteins. The µ-calpain and calpastatin were eluted with 80 ml of 200 mM NaCl elution buffer, the m-calpain was subsequently eluted with 80 ml of 400 mM NaCl elution buffer. The eluted was collected 2 mL/fractions and measured at A280 nm and then the fraction consisted of protein were pooled for analysis of the calpains system activity. One unit of calpastatin activity was defined as the amount of the inhibitor that inhibits one unit of m-calpain activity. One unit of µ-calpain and m-calpain activity was defined as the amount of enzyme that catalysed an increase of 1.0 absorbance until at A280 nm [10].

2.4 Statistical Analysis

Completely Randomized Design (CRD) was used to design the experiment. Independent variable was aging period with separated into 6 levels (1, 3, 5, 7, 14, and 21 days). Shear force values, and µ-calpain, m-calpain and calpastatin activities were dependent variables. Ducan’s New Multiple Range Test was used to compare the difference of means. The Pearson Correlation between the shear force value and the enzyme activities was also analysed.

3 Results and discussions

3.1 Shear Force Values

The shear force values decreased dramatically from day 1 to 7 postmortem aging from 9.01±0.83 kg/cm² to 6.47±1.12 kg/cm² (p<0.01) and then declined slowly to 4.34±0.10 kg/cm² after 21 days of aging (P<0.01), as shown in Table 1.

| Aging period (day) | Shear force values (kg/cm²) |
|--------------------|-----------------------------|
| 1                  | 9.01±0.83^a                 |
| 3                  | 8.26±0.63^b                 |
| 5                  | 6.92±0.67^c                 |
| 7                  | 6.47±1.12^c                 |
| 14                 | 5.12±0.88^bc                |
| 21                 | 4.34±0.10^d                 |

a,b,c Different superscripts showed highly significant differences (P<0.01)

After 3 days of aging, the shear force value was 8.20 kg/cm², however, the values could be varied between 2.1 to 4.9 kg/cm² [6]. In this study, the longer aging period decreased shear force values in agreement with the previous report found in the loin muscle of red deer (Cervus elaphus) (P<0.001) [11]. Likewise, the tenderness of loin muscle of red deer was improved after 21 days of aging [12].

3.2 Calpain/calpastatin activities

After calpain analysis, the results showed that the µ-calpain activity decreased significantly from 1.50±0.42 to 0.19±0.28 units/g of meat (P<0.01), whereas m-calpain activity decreased slightly from 22.88±9.64 to 16.95±8.34 units/g of meat and calpastatin activity decreased slightly from 9.93±2.37 to 6.82±2.96 units/g of meat (P>0.05) during aging period, as present in the Table 2.

| Aging period (day) | µ-calpain | m-calpain | Calpastatin |
|--------------------|-----------|-----------|-------------|
| 1                  | 1.50±0.42^a| 22.88±9.64| 9.93±2.37   |
| 3                  | 1.05±0.54^b| 21.10±8.57| 9.29±2.10   |
| 5                  | 0.74±0.47^c| 20.19±8.94| 8.96±1.99   |
| 7                  | 0.60±0.46^d| 20.02±8.95| 7.59±2.60   |
| 14                 | 0.46±0.33^c| 18.68±8.72| 7.18±3.00   |
| 21                 | 0.19±0.28^c| 16.95±8.34| 6.82±2.96   |

a,b,c Different superscripts in column show highly significant differences (P<0.01)

In this study, µ-calpain activity decreased significantly during aging time. The result agreed with previous study which found that the µ-calpain activity was gradual decline (P<0.05) after 1 and 3 days postmortem, and after 15 days postmortem µ-calpain activity was not detected (P>0.05) [17]. At the same time, µ-calpain was activated and then they activity lost though an autolytic process [6]. Similarity to the change of calpain/calpastatin activity in beef, the activity of µ-calpain decreased rapidly during postmortem aging but activity of m-calpain activity changed slightly during the first 7 day, whereas calpastatin activity decreased substantially during this period [18].
3.3 Correlation of shear force values and Calpain/calpastatin activities

The correlation between shear force values and μ-calpain, m-calpain and calpastatin activities (Table 3) shows some interesting among the analysis variables. Shear force value was significantly correlated with higher levels of μ-calpain activity \((r = 0.915)\) and m-calpain activity \((r = 0.758)\), respectively. However, the value was not significantly related to calpastatin activity \((r = 0.462)\). The activities of m-calpain and μ-calpain had highly significantly related \((r = 0.852)\). Furthermore, both had significantly correlated with calpastatin activity \((r = 0.852)\). These results summarized that there was the correlation between shear force value, μ-calpain, and m-calpain activities \((P<0.01)\), but not calpastatin activity.

There were reported that the postmortem storage and processing affect the meat tenderness [13], and the most of postmortem tenderness improvement is attributed to μ-calpain [14], because after aging storage, the myofibrillar proteins were degraded by calpain system enzyme. They broke muscle protein by autolysis, thus, the resulting in the degradation of myofibrillar proteins and therefore improved tenderness [15-16]. These findings are consistent with previous reports as it showed that a strong correlation between the calpain and meat tenderization postmortem [19]. However, some reported that there was the good correlation between calpastatin activity and shear force in fallow deer meat [20]. The rate of tenderization indicates that the calpain and calpastatin system are closely linked to the proteolytic breakdown of myofibrillar proteins [21].

Table 3. Pearson’s correlation coefficients between shear force and μ-calpain, m-calpain and calpastatin

|                  | μ-calpain | m-calpain | calpastatin |
|------------------|-----------|-----------|-------------|
| Shear force      | 0.915**   | 0.758**   | 0.462**     |
| μ-calpain        | 0.632**   | 0.745**   | 0.852**     |
| m-calpain        | 0.852**   |           |             |

*ns non significant difference \((P>0.05)\), and ** \(P<0.01\)

In conclusion, this study confirms that in the case of rusa deer, μ-calpain plays a key factor controlling postmortem meat tenderness compared to m-calpain and calpastatin. We suggest that postmortem storage should not exceed 7 days is enough to achieve aging of the LD muscle, which may help to reduce the cost of meat production.
