Estimates on the Size of Symbol Weight Codes
Yeow Meng Chee, Senior Member, IEEE, Han Mao Kiah, Student Member, IEEE, Punarbasu Purkayastha, Member, IEEE

Abstract—The study of codes for powerline communications has garnered much interest over the past decade. Various types of codes such as permutation codes, frequency permutation arrays, and constant composition codes have been proposed over the years. In this work we study a type of code called the bounded symbol weight codes which was first introduced by Versfeld et al. in 2005, and a related family of codes that we term constant symbol weight codes. We provide new upper and lower bounds on the size of bounded symbol weight and constant symbol weight codes. We also give direct and recursive constructions of codes for certain parameters.

Index Terms—Asymptotic bounds, Constant composition codes, Powerline communications, Reed Solomon codes, Symbol weight codes.

I. INTRODUCTION

The notion of transmitting data over powerlines has posed an interesting challenge for information and coding theory. The noise characteristics of such a communication channel include permanent narrowband noise, impulse noise and white Gaussian noise. Communication over this channel also has an additional requirement that the power envelope be as close to constant as possible. Vinck [31] studied this channel and showed that M-ary Frequency Shift Keying (M-FSK) modulation, in conjunction with the use of permutation codes, provides a constant power envelope, frequency spreading and redundancy to correct errors resulting from the harsh noise pattern. This has since resulted in research on Frequency Permutation Arrays (FPAs) and constant composition codes (CCCs) which retain the property of a constant power envelope (see [5]–[16], and [14] for a survey). Every codeword of an FPA or a CCC has the requirement that the frequency of each symbol is fixed by the parameters of the code. Versfeld et al. [29] introduced the notion of the “same-symbol weight” of a code by relaxing the requirement that every symbol must occur a fixed number of times in any codeword. In every codeword of a same-symbol weight code, the frequency of any symbol is bounded. Even with this relaxation it is possible to detect permanent narrowband noise. Versfeld et al. [29], [30] used Reed-Solomon codes to design codes with specified same-symbol weight.

In this work we mostly study the asymptotic behavior of codes in the symbol weight space. We use the term bounded symbol weight (as opposed to same-symbol weight [29]) to denote all words in the Hamming space with bounded symbol weight, that is, any symbol in a codeword does not occur more than a fixed number of times, say $r$. This terminology is adopted in order to distinguish this space from the constant symbol weight space, in which every symbol in a word in the Hamming space occurs at most $r$ times and there exists one symbol which occurs exactly $r$ times. The constant symbol weight space is clearly a subset of the bounded symbol weight space. We also use the term symbol weight space to refer to either the bounded symbol weight or constant symbol weight space. The actual space being referred to is made clear from the context and notation.

As described in [29], [30], the symbol weight determines whether the code can detect and correct narrowband noise in the powerline channel. An FPA or a CCC belongs to some constant symbol weight space. The constant symbol weight space also contains other compositions all of which have the same maximal part, that is, all such codes have the same fixed symbol weight. Thus a code in the constant symbol weight space is larger than a CCC of a fixed composition, and is still relevant for correcting narrowband noise. The asymptotic behavior of FPAs have been studied in [4], [8], [14]. In contrast, there are relatively fewer results on the asymptotic behavior of CCCs (see [23], [28]). We consider familiar techniques used to derive classical bounds such as the GV bound, the Johnson bound and the Singleton bound, on codes in the symbol weight space. However, the derivation of these results are not immediate because of the lack of any reasonable structure in the symbol weight spaces. In particular, even the Hamming balls of a fixed radius in these spaces depend on the center of the ball. In Section IV we also study non-asymptotic bounds on codes in the symbol weight spaces by expressing them in terms of different CCCs. This also raises related combinatorial questions regarding the size and construction of optimal codes, which can be an interesting avenue of future research. In later sections we show that there exists codes, which are subsets of Reed-Solomon codes, with high rate and relative distance, which are a subset of the constant symbol weight space.

Throughout this work we are mostly concerned with codes that have positive rate and positive relative distance. Hence we do not study codes with very large distances, in the Plotkin region. We start with some basic definitions and notations in the following section. We devote Section III to deriving the exact and asymptotic size of the symbol weight spaces. The results in Section III allow us to determine which constant composition space contained within the symbol weight space contributes the most to the rate of a symbol weight space. These estimates are used in Section IV to determine upper and lower bounds on symbol weight space and constant symbol weight codes. In particular, it is clear that asymptotically some constant composition code determines the rate of a symbol.
weight code. An upper bound is readily obtained from either the Singleton bound or the Linear Programming bound in the Hamming space. In Section IV we also provide a Johnson-type bound on codes in the constant symbol weight space, and use this bound to derive an asymptotic improvement of the Singleton bound and the Linear Programming bound for certain ranges of the minimum distances and the symbol weight. In Section V we provide non-asymptotic lower bounds on symbol weight codes. We introduce a new metric on the space of compositions of an integer and use this metric to lower bound the size of symbol weight codes by a sum of sizes of compositions of an integer and use this metric to determine a GV-type bound on symbol weight codes, and in particular show that the asymptotic lower bound presented in Section III is tight for certain parameters, for subcodes of Reed-Solomon codes.

II. Preliminaries

Let \( \mathbb{Z}_q = \{0, \ldots, q - 1\} \) denote an alphabet set of \( q \) elements. We consider symbol weight codes in the Hamming space \( \mathbb{Z}_q^n \). The symbol weight of a word is defined as the maximum of the frequencies of occurrences of symbols in the word. For instance, the all-0 word has a symbol weight of \( n \). The bounded symbol weight space with symbol weight \( r \) is the set of all words with symbol weight at most \( r \). This space is denoted by \( SW(n, q, r) \). The bounded symbol weight space is termed as “same-symbol weight space" in the works of Versfeld et al. \cite{29, 30}. We adopt this terminology to distinguish this space from the constant symbol weight space that we define next. In the constant symbol weight space every word has a symbol weight of exactly \( r \). This space is denoted as \( SW(n, q, r) \). If every symbol occurs in each codeword we can use the Pigeonhole principle to get the lower bound \( r \geq \lceil n/q \rceil \). Since any word with this lowest value of symbol weight contains the least repetition of any symbol, these words are considered as ones with the optimal symbol weight.

In this work we study codes in the bounded and constant symbol weight spaces. A bounded (resp. constant) symbol weight code is a subset of the bounded (resp. constant) symbol weight space. Let \( A_q^{SW}(n, d, \leq r) \) (resp. \( A_q^{SW}(n, d, r) \)) denote the maximum size of a bounded (resp. constant) symbol weight code with distance \( d \) in \( SW(n, q, \leq r) \) (resp. \( SW(n, q, r) \)). We denote a composition of \( n \) into \( q \) non-negative parts by \( \mathbf{n} = [n_0, n_1, \ldots, n_{q-1}] \). The constant composition space with composition \( \mathbf{n} = [n_0, n_1, \ldots, n_{q-1}] \) is a subset of \( Z_q^n \) in every word of which the \( i \)-th symbol occurs exactly \( n_i \) times. A constant composition code is a subset of a constant composition space. We use the notation \( A_q(n, d) \) to denote the maximum size of a code in the constant composition space given by the composition \( \mathbf{n} \) and minimum distance at least \( d \). We use the notation \( A_q(n, d) \) to denote the maximum size of a code with minimum distance at least \( d \) in the Hamming space. A code \( C \) of length \( n \), size \( M \), distance \( d \), over \( \mathbb{Z}_q \) is denoted by \( C(n, M, d) \). If \( C \) has a constant symbol weight \( r \) it is denoted by \( C(n, M, d, r) \). If \( C \) is a linear code of dimension \( k \) over a field \( \mathbb{F}_q \) it is denoted as \( C[n, k, d] \).

An FPA consists of vectors in which every symbol occurs a fixed number, say \( \lambda \), of times. Hence, an FPA is a CCC with composition \( \mathbf{n} = [\lambda, \ldots, \lambda] \). Thus the FPA is a subset of the constant symbol weight space with symbol weight \( \lambda \). Similarly, it can be seen that a CCC with composition \( n = [n_0, \ldots, n_{q-1}] \) is a subset of the constant symbol weight space with symbol weight \( r = \max \{n_i : i = 0, \ldots, q - 1\} \).

The coded modulation scheme introduced by Vinck \cite{31} for the powerline channel considered \( M \)-FSK modulation along with the use of permutation codes. The demodulator considered is a hard-decision demodulator consisting of an envelope detector with a threshold. At every time instance, the demodulator provides a multivalued output consisting of all the symbols that correspond to frequencies at which the output of the envelope detector exceeds the threshold. A narrowband noise in this context results in the same symbol appearing at all time instances. As explained in Versfeld et al. \cite{29}, a linear code is less effective in this channel. For instance, the all-zero codeword can not be distinguished from a narrowband noise. Hence, permutation codes, FPAs and CCCs are more suitable for communication in this channel. To understand why we study the constant symbol weight space, consider the following example.

Example 2.1: Consider a CCC in \( \mathbb{Z}_q^n \) with composition \( [1, 1, 3, 3] \) and minimum distance \( d = 4 \), that is suitable for correcting narrowband noise in a powerline channel. Let \( (0, 1, 2, 2, 2, 3, 3, 3) \) be a codeword in this CCC. Then the vector \( (0, 0, 0, 1, 1, 1, 2, 3) \) is also a suitable vector for correcting narrowband noise. However this vector belongs to a different constant composition space that contains vectors with composition \( [3, 3, 1, 1] \). Both these constant composition spaces are a subset of the constant symbol weight space with symbol weight \( 3 \). In Section V we prove that since the compositions \( [1, 1, 3, 3] \) and \( [3, 3, 1, 1] \) have distance \( 4 \) in a specific metric that we define later, any vector from the constant composition space with composition \( [1, 1, 3, 3] \) will be at a distance at least \( 4 \) from any vector of the other space with composition \( [3, 3, 1, 1] \). Hence, we can increase the size of the code by including all the codewords from a CCC in the latter space.

It is clear that any constant symbol weight space with symbol weight \( r \) can be written as the union of different constant composition spaces, each of which contains vectors with the same symbol weight \( r \). This relation to the constant composition space is used throughout this work.

In the next section, we first determine the size of the constant symbol weight space and the bounded symbol weight space. This size is then used to determine a GV-type bound on the symbol weight spaces. Unfortunately, the expression for the size of the symbol weight spaces is unwieldy and gives little insight into the behavior of the lower bounds. The symbol weight spaces are also not ball-homogeneous, that is, the size of a Hamming ball in the space depends on the center of the ball. For example, the bounded symbol weight space in \( \mathbb{Z}_q^n \) with symbol weight \( r \) at most \( 2 \) has \( 24 \) vectors. The ball of radius \( 1 \) around the vector \( (1, 0, 0) \) contains \( 6 \) vectors, namely, \( (1, 0, 0), (2, 0, 0), (1, 1, 0), (1, 2, 0), (1, 0, 1), (1, 0, 2) \). In contrast, the ball of radius \( 1 \) around
(2, 1, 0) contains 7 vectors, namely, (2, 0, 0), (0, 1, 0), (1, 1, 0), (2, 1, 0), (2, 2, 0), (2, 1, 1), (2, 1, 2). This fact makes it difficult to state decent lower bounds. Similar comments apply to the computation of the Hamming bound. Hence, in the following two sections, we instead study the asymptotic behavior of the symbol weight spaces and the rate of the corresponding symbol weight codes.

In the following section we determine the asymptotic size of the symbol weight space. This enables us to determine which constant composition space, contained within the symbol weight space, has the largest size.

III. ASYMPTOTIC SIZE OF THE SYMBOL WEIGHT SPACE

To determine the asymptotic size of the symbol weight space we first state the expression for the non-asymptotic case. Each vector in the symbol weight space corresponds to a vector in some constant composition space. Hence we introduce some basic definitions below to describe the size of the symbol weight space. Let us denote the set of all compositions of \( n \) into \( q \) non-negative parts by \( N \), that is

\[
N \triangleq \left\{ n \in \mathbb{Z}^q : n \geq 0, \sum_{i=0}^{q-1} n_i = n \right\},
\]

and define

\[
N(r) \triangleq \left\{ n \in N : \max \{n_0, \ldots, n_{q-1}\} = r \right\},
\]

\[
N(\leq r) \triangleq \left\{ n \in N : \max \{n_0, \ldots, n_{q-1}\} \leq r \right\}.
\]

Let \( P(N, K, R) \) denote the compositions of \( n \) into \( K \) parts, each part bounded between \( 0 \) and \( R \). An expression for the size of \( P(N, K, R) \) is given by \([13, \text{pp. 1037}],\)

\[
|P(N, K, R)| = \sum_{i} (-1)^{i} \binom{K}{i} \frac{(K + N - (R + 1)i - 1)!}{K!}.
\]

Define \( k_0 \) to be \( k_0 \triangleq \max \{n - (r - 1)q, 1\} \). The quantity \( k_0 \) corresponds to the smallest number of symbols that can occur with frequency exactly \( r \) in any vector with symbol weight \( r \). The size of the set \( N(r) \) is given by the following lemma.

**Lemma 3.1:**

\[
|N(r)| = \sum_{k=k_0}^{[n/r]} \binom{q}{k} |P(n-rk, k-r, 1)|,
\]

and

\[
k_0 = \max \{n - (r - 1)q, 1\} = \begin{cases} q - \Delta, & r = \left\lfloor \frac{q}{r} \right\rfloor = \frac{n + \Delta}{q}, \\ 1, & \text{otherwise}, \end{cases}
\]

for some \( \Delta \equiv \Delta(n, q) \) such that \( 0 \leq \Delta \leq q - 1 \).

**Proof:** If a vector \( \mathbf{v} \in \mathbb{Z}_q^n \) has a composition \( n \) such that exactly \( k \) of the symbols in \( \mathbb{Z}_q^n \) have composition \( r \) in \( \mathbf{v} \), then the rest of the symbols must satisfy the inequality

\[
n - rk \leq (q-k)(r-1).
\]

This inequality, in conjunction with the requirement that at least one symbol must have composition \( r \), determines the value of \( k_0 \). If a composition \( n \) has exactly \( k \) symbols with the value \( r \), then these \( k \) symbols can be chosen in \( \binom{q}{r} \) ways. The rest of the elements of \( n \) must correspond to a composition of \( n - rk \) into \( q - k \) parts, each part bounded between \( 0 \) and \( r - 1 \).

Note that \( r \) must satisfy \( r \geq \lfloor n/q \rfloor \). We have

\[
n - (r - 1)q \geq 1 \iff r \leq \frac{n + q - 1}{q}.
\]

There is exactly one integer \( r \) which satisfies \( \lfloor n/q \rfloor \leq r \leq (n + q - 1)/q \). This value of \( r \) is given by \( r = (n + \Delta)/q \), for some \( \Delta \) such that \( 0 \leq \Delta \leq q - 1 \).

The size of the constant symbol weight space \( SW(n, q, r) \) can now be determined to be

\[
|SW(n, q, r)| = \sum_{k=k_0}^{[n/r]} \binom{q}{k} \left( \sum_{x \in P(n-rk, k-r, 1)} \left( \binom{n-rk}{x_1, \ldots, x_{q-k}} \right) \right),
\]

where \( x = (x_1, \ldots, x_{q-k}) \), and \( r \) is repeated \( k \) times in the multinomial coefficient \( \binom{n}{x_1, \ldots, x_{q-k}} \). The size of the bounded symbol weight space is a sum of the sizes of the different constant symbol weight spaces, as shown below:

\[
|SW(n, q, \leq r)| = \sum_{s=\lfloor n/q \rfloor}^{n} \binom{q}{s} \left( \sum_{x \in P(n-sk, k-s, 1)} \left( \binom{n-sk}{x_1, \ldots, x_{q-k}} \right) \right) = \sum_{y \in P(n, q, r)} \binom{n}{y_1, \ldots, y_q},
\]

where \( x = (x_1, \ldots, x_{q-k}) \), \( y = (y_1, \ldots, y_q) \), and \( k_0(s) = \max \{n - (s - 1)q, 1\} \).

The expressions in the equations above can be used to provide GV-type existence bounds on symbol weight codes. A GV bound on the size of a code \( \mathcal{C} \) with minimum distance \( d \) in a space \( S \) is given as

\[
|\mathcal{C}| \geq \left\lfloor \frac{|S|}{V(S, d-1)} \right\rfloor,
\]

where \( V(S, d-1) \) is the volume of a ball of radius \( d-1 \) in the space \( S \). Although the sizes of the constant and bounded symbol weight spaces are given by the above equations \([4, 6]\), respectively, there are several hurdles in applying the GV-type bound directly. First the space itself lacks any suitable structure and is not even ball-homogeneous. Even for the special case of an FPA in which all the symbols occur equally often in every vector, the expression for the GV (and also the Hamming bound) is quite unwieldy because the size of the ball does not have a nice form; see Huczynska \([15, \text{Theorem 2.7}]. \)

Secondly, the expressions for the sizes of the spaces are not suitable for expressing the bound in a simple form. We instead study the asymptotic form of this bound in the next section. To determine the asymptotic results, we first need to understand the behavior of the sizes of the symbol weight spaces for large block length \( n \).
The expression for the asymptotic size of the constant symbol weight space is given by the following theorem. A similar expression for the bounded symbol weight space can be readily derived from this theorem, and is mentioned at the end of this section. The following theorem holds for any $q$ such that $q$ grows at most proportional to $n$. Note that all the asymptotics are with respect to $n$ and so the term $o(1)$ below goes to zero as $n$ goes to infinity.

**Theorem 3.2:** For any $q$, such that $q = \theta n^r$, where $\theta$ is a positive constant and $0 \leq \epsilon \leq 1$,
\[
\frac{1}{n} \log_q |SW(n, q, r)| = \begin{cases} \frac{h_q}{n} (1 - \frac{\epsilon}{n}) - o(1), & r > \lfloor \frac{n}{q} \rfloor, \\ 1 - o(1), & r = \lfloor \frac{n}{q} \rfloor. \end{cases}
\]

We first give a brief outline of the proof of this theorem. As mentioned earlier, a constant symbol weight space with symbol weight $r$ is a union of several constant composition spaces, each of which contains vectors of symbol weight $r$. We first show in Lemma 3.3 that the number of constant composition spaces does not contribute to the rate of the constant symbol weight space. This is not surprising and it is true even for the Hamming space, when considered as a union of constant composition spaces. Because of this Lemma, we now know that there is a constant composition space which dominates the expression for the rate. Lemma 3.4 and 3.5 below help us determine this dominant term. It turns out that this dominant term comes from the constant composition space which has exactly $k_0$ symbols that occur exactly $r$ times in any vector.

We continue with the proof of the theorem, by first establishing a sequence of lemmas presented below. Let $h_p(x)$ be the $p$-ary entropy function defined in the range $0 \leq x \leq 1$ as
\[
h_p(x) \equiv -x \log_p \frac{x}{p-1} - (1-x) \log_p(1-x).
\]

**Lemma 3.3:**
\[
\frac{1}{n} \log_q |N(r)| = o(1).
\]

**Proof:** The number of terms in the summation over the range $k_0 \leq k \leq \lfloor n/r \rfloor$ is at most $n$. Hence only one of the terms in the summation dominates in the asymptotics. We note that $|P(n-rk, q-k, k, r-1)| \leq |N|$. Also, $|N| = \binom{n+q-1}{q-1}$ (see [27] pp. 415). For a constant $q$, it shows that $P(n-rk, q-k, k, r-1)$ grows at most polynomially in $n$ and hence
\[
\frac{1}{n} \log_q |N(r)| = \frac{1}{n} \log_q |P(n-rk, q-k, k, r-1)| + o(1) \\
\leq \frac{1}{n} \log_q (an^{q-1}) + o(1) \\
= o(1),
\]
for some positive constant $a$. For $q = \theta n^r$, $0 < \epsilon \leq 1$, and positive constant $\theta$, we get
\[
\frac{1}{n} \log_q \left( \frac{q}{k} \right) \leq \frac{q}{n} h_2 \left( \frac{k}{q} \right) \log_q 2 + o(1) = o(1),
\]
and hence
\[
\frac{1}{n} \log_q |P(n-rk, q-k, r-1)| \leq \frac{n + q - 1}{n} \times \frac{q - 1}{n + q - 1} \log_q 2 + o(1) = o(1).
\]

By the above lemma, we can conclude that in the asymptotics of $|P|$ only one term from $\binom{n-rk}{q-k} \binom{r-1}{r-k}$ is present in the asymptotics. The dominant multinomial terms are given by an optimal choice of $k$. First, we determine the dominating multinomial term from the inner summation in $|P|$. We use the following lemma. Let $\Gamma(x)$ denote the Gamma function,
\[
\Gamma(x) = \int_0^\infty t^{x-1}e^{-t}dt.
\]
In particular, for an integer $x$, $\Gamma(x) = (x-1)!$.

**Lemma 3.4:** [25] pp. 109] Let $x_1, \ldots, x_K$ be non-negative real numbers. Then
\[
\prod_{i=1}^K \Gamma(x_i) \geq \left( \Gamma \left( \frac{\sum x_i}{K} \right) \right)^K.
\]

This lemma immediately implies that $\binom{n}{x_1, \ldots, x_K} \leq \binom{N}{n/k, \ldots, n/k}$. Hence the dominating term in the inner summation in $|P|$ is given by $\binom{n-rk}{q-k}$.

For large $n$, we obtain the following asymptotic expression for $|SW(n, q, r)|$:
\[
\frac{1}{n} \log_q |SW(n, q, r)| = \log_q n - \frac{r}{n} \log_q r - \frac{n - rk}{n} \times \log_q (n-rk) + \frac{n-rk}{n} \log_q (q-k) + \frac{1}{n} \log_q \left( \frac{q}{k} \right) + o(1).
\]

Neglecting the $o(1)$ term, the maximum of the expression in equation $\square$ over $k$ yields the rate of the constant symbol weight space. Unfortunately, a closed-form expression for the optimizing value of $k$ seems difficult to achieve, even if $k$ is considered over reals instead of integers. We instead look at how the expression behaves for large $n$. The lemma below asserts that the maximum is achieved at $k^* = k_0$ as $n \to \infty$.

**Lemma 3.5:** Let $\{f_n(x)\}_{n=1}^\infty$ be a family of bounded, strictly monotonic decreasing functions in $x$, defined over the domain $x \in [x_0, X_0]$, such that $\lim_{n \to \infty} f_n(x) = f(x)$. Let $\{g_n(x)\}_{n=1}^\infty$ be a family of non-negative functions such that $0 \leq g_n(x) \leq C_n$, where $C_n$ depends only on $n$ and $\theta$.

1 We ignore the fact that the ratios may not be integers. This argument can be made more rigorous, but cumbersome, by taking the composition to be $l_0 = \left[ \frac{n-rk}{q-k} \right]$ for $(q-k)(1 - \left[ \frac{n-rk}{q-k} \right])$ times and $l_1 = \left[ \frac{n-rk}{q-k} \right]$ for $(q-k)(\left[ \frac{n-rk}{q-k} \right])$ times, where $\{x\}$ denotes the fractional part of a real number $x$. It is common to use $\lfloor x \rfloor$ and $\{x\}$ to denote the floor and fractional parts, respectively.
We also get \( k \) be defined over integer \( x \in [0, X_0] \). Now, \[
\max_{x \in [0, X_0]} f_n(x) + g_n(x) = f(x_0) = \lim_{n \to \infty} \max_{x \in [0, X_0]} f_n(x) + g_n(x).
\]

Proof: The strict monotonicity \( f_n(x) > f_n(y) \) for any \( x, y, x_0 \leq x < y \leq X_0 \), implies that \( f(x_0) \geq f(x) \) for all \( x \in [x_0, X_0] \). Now, \[
\max_{x \in [0, X_0]} f_n(x) + C_n \geq \max_{x \in [0, X_0]} f_n(x) + g_n(x) \geq \max_{x \in [0, X_0]} f_n(x) \Rightarrow f_n(x_0) + C_n \geq \max_{x \in [0, X_0]} f_n(x) + g_n(x) \geq f_n(x_0) \Rightarrow \lim_{n \to \infty} \max_{x \in [0, X_0]} f_n(x) + g_n(x) = f(x_0).
\]

We also get \[
\max_{x \in [0, X_0]} f_n(x) + g_n(x) = \lim_{n \to \infty} f_n(x) = f(x_0).
\]

This lemma implies that we can determine the asymptotic optimum of \( f_n(x) + g_n(x) \) by simply taking the limit of the sequence of numbers \( f_n(x_0) + g_n(x_0) \), which converges to \( f(x_0) \).

**Proof of Theorem 3.2** We apply Lemma 3.5 as follows.

Let \[
F_n(k) = \log_n n - k \frac{r}{n} \log n - \frac{n - r k}{n} \log_q (n - r k) + \frac{n - r k}{n} \log_q (q - k),
\]
\[
G_n(k) = \frac{1}{n} \log_q \left( \frac{q}{k} \right),
\]
be defined over integer \( k \in [k_0, [n/r]] \). \( G_n(k) \) can be upper bounded by a term independent of \( k \), \[
G_n(k) \leq \frac{1}{n} \log_q \left( \frac{q}{q/2} \right),
\]
and \( \lim_{n \to \infty} \frac{1}{n} \log_q \left( \frac{q}{q/2} \right) = 0 \). We now note that for every \( n \neq rq \), \( F_n(k) \) is strictly monotonically decreasing. To establish this we relax \( k \) to reals and consider the derivative \( F_n'(k) \). We get \[
nF_n'(k) = -r \log_q r + r \log_q \frac{n - r k}{q - k} + r - \frac{n - r k}{q - k} = r \left( \log_q \frac{n - r k}{r(q - k)} - \left( \frac{n - r k}{r(q - k)} - 1 \right) \right) \leq 0,
\]
where the last line follows because of the fact that \( n - r k \leq r(q - k) \), and that \( \log x \leq (x - 1) \) for \( 0 < x \leq 1 \), with equality at \( x = 1 \). We also note that \( n - r k < r(q - k) \) if and only if \( n \neq rq \). Hence \( F_n'(k) \) is strictly monotonically decreasing for \( n \neq rq \). For \( n = rq \), \( F_n(k) \) is a constant independent of \( k \) and \( k_0 = q \), and hence the optimal value of \( F_n'(k) \) is at \( k = q \). Since Lemma 3.5 is applicable to \( F_n(k) + G_n(k) \), we concentrate only on determining the asymptotics of \( F_n(k_0) \).

For \( r > \lceil n/q \rceil \) we get \( k_0 = 1 \) and \[
F_n(1) = \frac{r}{n} \log_q r - \left( 1 - \frac{r}{n} \right) \log_q \left( 1 - \frac{r}{n} \right) + \left( 1 - \frac{r}{n} \right) \log_q (q - 1) - o(1)
\]
\[
= h_q \left( 1 - \frac{r}{n} \right) - o(1).
\]

For \( r = \lceil n/q \rceil = (n + \Delta)/q \), we have \( k_0 = q - \Delta = n - (r - 1)q \), and \[
F_n(q - \Delta) = \frac{\Delta(r - 1)}{n} \log_q \frac{r}{r - 1} - \log_q \frac{n + \Delta}{n q} = 1 - o(1).
\]

This proves Theorem 3.2.

The exponent of the asymptotic size of the bounded symbol weight space \( SW(n, q, \lceil n/q \rceil) \) is always \( n(1 - o(1)) \) since it contains \( SW(n, q, \lceil n/q \rceil) \).

**IV. ASYMPTOTIC SIZE OF SYMBOL WEIGHT CODES**

In this section we provide estimates on the rate of symbol weight codes for all \( q = \theta n^\epsilon \), for any positive constant \( \theta \), and for \( 0 \leq \epsilon \leq 1 \). We considered the asymptotic behavior of the symbol weight spaces because of the difficulty in determining reasonable expressions for fixed \( n \). Below, we determine upper and lower bounds on the rate of a symbol weight code. First we determine a GV-type bound in Theorem 4.3 below. The Singleton and Linear Programming (LP) upper bounds on codes in the Hamming space are applicable to the symbol weight codes too. In Theorem 4.4 we show that for constant symbol weight codes, the Singleton and LP upper bounds can be improved substantially for a specific range of the symbol weight.

The following lemma is immediate and it shows that the rate of symbol weight codes can be given in terms of the rate of a CCC.

**Lemma 4.1:**

\[
\frac{1}{n} \log_q A_q^{SW}(n, d, r) = \frac{1}{n} \max_{d \in N(r)} \log_q A_q(n, d) + o(1),
\]
\[
\frac{1}{n} \log_q A_q^{SW}(n, d, \leq r) = \frac{1}{n} \max_{d \in N(\leq r)} \log_q A_q(n, d) + o(1).
\]

(5)

Proof: Note that we clearly have the following upper and lower bounds on \( A_q^{SW}(n, d, r) \):

\[
\max_{d \in N(r)} A_q(n, d) \leq A_q^{SW}(n, d, r) \leq |N(r)| \max_{n \in N(r)} A_q(n, d).
\]

(6)

The lemma now follows from an application of Lemma 3.3. The second expression in (5) can be determined similarly.

We state the LP upper bound on codes in the Hamming space from Aaltonen [2].

**Theorem 4.2:**

\[
\limsup_{n \to \infty} \frac{1}{n} \log_q A_q(n, d) \leq h_q(k_q(\delta)), \quad 0 \leq \delta \leq \frac{q - 1}{q},
\]

where \( h_q(k_q(\delta)) \) is the entropy of the distributed source with probability mass function \( \{ q/k_q(\delta), 1 - q/k_q(\delta) \} \).

Theorem 4.2 is due to Aaltonen [2].
where \( k_q(x) = \frac{q^2 - 1}{q^2 - 2x + \frac{q^2}{q} - 1} \), \( 0 \leq x \leq 1 \).

An upper bound on symbol weight codes is readily obtained by an upper bound on codes in the Hamming space, since
\[
A_q^{SW}(n, d, r) \leq A_q^{SW}(n, d, \leq r) \leq A_q(n, d).
\]
Thus for constant \( q \) the LP bound is also an upper bound on symbol weight codes. For \( q \) growing with \( n \), the Singleton bound is an upper bound on symbol weight codes. Below, we provide asymptotic estimates of symbol weight codes.

**Theorem 4.3:** Let \( q = \theta n^\epsilon \), where \( 0 < \theta \) is a constant, and \( 0 \leq \epsilon \leq 1 \). Let \( d/n \to \delta \) and \( r/n \to \rho \) as \( n \to \infty \), where \( 0 < \delta \leq 2^{1/q} \). Then for \( q \) constant, i.e., \( \epsilon = 0 \),
\[
\lim_{n \to \infty} \frac{1}{n} \log_q A_q^{SW}(n, d, r) = h_q(1 - \rho) - h_q(\delta),
\]
\[
\lim_{n \to \infty} \frac{1}{n} \log_q A_q^{SW}(n, d, \leq r) = 1 - h_q(\delta).
\]

For \( q \) increasing with \( n \) one can use the Singleton bound. Thus for \( \epsilon < 1 \), we get
\[
\lim_{n \to \infty} \frac{1}{n} \log_q A_q^{SW}(n, d, r) = 1 - \rho - \delta, \quad r = \rho n,
\]
\[
\lim_{n \to \infty} \frac{1}{n} \log_q A_q^{SW}(n, d, \leq r) = 1 - \delta, \quad r = o(n),
\]
\[
\lim_{n \to \infty} \frac{1}{n} \log_q A_q^{SW}(n, d, \leq r) = 1 - \delta, \quad \text{any } r.
\]

**Remark:** Note that for \( q \) increasing with \( n \) the following limits can be inferred,
\[
\lim_{n \to \infty} \frac{1}{n} \log_q A_q^{SW}(n, d, r) = \lim_{n \to \infty} \frac{1}{n} \log_q A_q(n, d), \quad r = o(n),
\]
\[
\lim_{n \to \infty} \frac{1}{n} \log_q A_q^{SW}(n, d, \leq r) = \lim_{n \to \infty} \frac{1}{n} \log_q A_q(n, d), \text{ any } r.
\]

**Proof:** We use the following lower bound on the constant symbol weight space, which is actually an Elias-type bound on the Hamming space (see Levenshtein [19]). This is followed by using the GV bound in the Hamming space.
\[
A_q(n, d) \leq \frac{q^n}{SW(n, q, r)} A_q^{SW}(n, d, r)
\]
\[
= \frac{1}{n} \log_q A_q^{SW}(n, d, r) \geq \frac{1}{n} \log_q A_q(n, d) + h_q \left( 1 - \frac{r}{n} \right) - 1 - o(1)
\]
\[
= h_q \left( 1 - \frac{r}{n} \right) - \frac{1}{n} \log_q V(Z_q^n, d - 1) - o(1)
\]
\[
= h_q \left( 1 - \frac{r}{n} \right) - h_q \left( \frac{d - 1}{n} \right) - o(1),
\]
where \( h_q(x) \) is the q-ary entropy function and \( V(Z_q^n, d - 1) \) is the volume of the ball of radius \( d - 1 \) in the Hamming space.

Similarly, for the bounded symbol weight space, we obtain
\[
\frac{1}{n} \log_q A_q^{SW}(n, d, \leq r) \geq 1 - h_q \left( \frac{d - 1}{n} \right) - o(1).
\]

For a constant \( q \), the asymptotics of these expressions are as given in [7].

For \( q \) growing with \( n \), the upper bound on the symbol weight codes is provided by the Singleton bound,
\[
A_q^{SW}(n, d, r) \leq A_q^{SW}(n, d, \leq r) \leq A_q(n, d) \leq q^{n-d+1}.
\]

Using the fact that \( h_q(x) = x \) in the limit as \( q \to \infty \), we get the results as stated in the theorem. In particular for \( r = o(n) \),
\[
\lim_{n \to \infty} h_q(1 - r/n) = 1 \quad \text{and} \quad \lim_{n \to \infty} h_q(d - 1/n) = \delta.
\]
Since \( A_q^{SW}(n, d, \leq r) \) is greater than \( A_q^{SW}(n, d, \lfloor n/q \rfloor) \), it gives the result stated in [8].

The lower bound [7] in the theorem may be interpreted as a GV-type bound in the symbol weight space that can be obtained if the volume of a ball of radius \( d - 1 \) in the symbol weight space is upper bounded by the volume of a ball of radius \( d - 1 \) in the Hamming space. Since, the symbol weight space is not ball-homogeneous, that is, the size of the balls of radius \( d - 1 \) depends on the center, we adopt the above method to derive the GV-type lower bound.

In the following theorem we provide an improvement on the upper bound for a constant symbol weight code with symbol weight \( r \).

**Theorem 4.4:** Let \( \lfloor n/q \rfloor \leq r \leq 2n/3 \) ; \( q = \theta n^\epsilon \) with \( 0 \leq \epsilon \leq 1 \). Let \( d \) satisfy \( r \leq d \). For \( n \to \infty \), let \( r/n \to \rho \), and \( d/n \to \delta \). Then, for constant \( q \),
\[
\limsup_{n \to \infty} \frac{1}{n} \log_q A_q^{SW}(n, d, r) \leq h_q \left( 1 - \frac{3}{2} \rho \right) - (1 - \rho) h_q \left( \frac{3}{2} \rho \right) + 1 - \frac{3}{2} \rho.
\]

For \( q \) growing with \( n \), we get
\[
\limsup_{n \to \infty} \frac{1}{n} \log_q A_q^{SW}(n, d, r) \leq 1 - \frac{3}{2} \rho.
\]

The proof of this theorem relies on a Johnson-type upper bound, and a lemma given below. We follow some elements of the derivation of the Singleton bound in Omran and Kumar [26]. However, our purpose is to improve the Singleton bound by using the parameters of the constant symbol weight space. The improvement mainly stems from the following lemma.

**Lemma 4.5:** Let \( d \geq r > 2n/3 \). Then \( A_q^{SW}(n, d, r) = q \).

**Proof:** We claim that if there are two codewords \( x, y \) both with symbol weight \( r \), then the symbol which repeats \( r \) times must be different in the two codewords. Suppose not. Then the two codewords \( x, y \) must have at least \( n - 2(n - r) \) coordinates which contain the same symbol. Thus the distance between the codewords is at most \( d \leq 2(n - r) \) which implies \( d < 2n/3 \), since \( r > 2n/3 \). This is a contradiction. We get \( A_q^{SW}(n, d, r) = q \). To show the opposite inequality, let \( x \) be a word with symbol weight \( r \), \( r > 2n/3 \). Then \( x + \alpha \mathbf{1}, \alpha \in Z_q^r \), where \( 1 \) is the all-one codeword, are also codewords with symbol weight \( r \). This establishes that \( A_q^{SW}(n, d, r) \geq q \).

We next give the Johnson-type bound.

[2]For certain parameters, better lower bounds on \( A_q(n, d) \), for instance from algebraic geometry codes, can improve on this GV bound on \( A_q^{SW}(n, d, r) \).
Lemma 4.6:

\[ A_q^{SW}(n, d, r) \leq \left\lceil \frac{\text{nq}}{n-r} A_q^{SW}(n-1, d, r) \right\rceil. \]

Proof: Consider the code-matrix of the constant symbol weight code with parameters \((n, M, d, r)\). Any row of the code-matrix has at least one symbol of frequency \(r\). Fix one symbol of frequency \(r\) in each row. There are a total \(M(n-r)\) symbols in the code-matrix which do not contribute to the symbol weight in any codeword. The average number of symbols, averaged over the \(n\) columns, with frequency at most \(r\) is then \(M(n-r)/n\). The average number per symbol, averaged over \(n\) columns and \(q\) symbols is \(M(n-r)/(qn)\). Thus, there exists at least one symbol \(\alpha\) and at least one column \(m\) such that the subcode consisting of the symbol \(\alpha\) in column \(m\) has size at least \(M(n-r)/(nq)\). Discarding the coordinate corresponding to \(m\) gives us the bound as stated in the Lemma.

Proof of Theorem 4.4: We now proceed to prove the theorem. Apply Lemma 4.6 recursively \(l+1\) times to get

\[ A_q^{SW}(n, d, r) \leq \left\lceil \frac{\text{nq}}{n-r} \cdots \left( \frac{(n-l)q}{n-l-r} \times A_q^{SW}(n-l-1, d, r) \right) \cdots \right\rceil. \]

The recursion stops for \(l\) such that \(r = \lceil 2(n-l-1)/3 \rceil\) and for \(d \geq r\). For this value of \(r\) and \(d\), \(A_q^{SW}(n, d, r) = q\), by Lemma 4.5. The condition \(l > 0\) implies \(r \leq 2n/3\). Constraints on \(l\) are obtained from the inequalities

\[ 2(n-l-1)/3 \leq r = \lceil 2(n-l-1)/3 \rceil \leq 2(n-l)/3. \]

This gives us the upper bound

\[ A_q^{SW}(n, d, r) \leq \left( \frac{n \cdots (n-l)}{(n-r) \cdots (n-l-r)} \right) q^{n-3r/2+1} = \left( \frac{n \cdots (n-l)}{(l+1)^{l+1}} \right) q^{n-3r/2+1}. \]

In the asymptotics as \(n \to \infty\) we get \(l/n \to 1 - 3/2r\). This gives us the upper bounds as stated in the theorem.

In the case of \(q\) growing with \(n\), this theorem improves on the Singleton bound \(1 - \delta\) for \(\delta < 3\rho/2\). The upper bound in Theorem 4.4 for constant \(q\) improves on the LP bound for certain range of parameters. The improvements are possible only for large \(\rho\) and for \(q \geq 5\). For \(\rho = 2, 3\) the restrictions \(\delta \geq \rho\) and \(\rho \leq 2/3\) do not leave room for improvement. For constant \(\rho\) the upper bound is in fact concave in shape. This can be verified by taking the second derivative with respect to \(\rho\), which results in the negative expression \(-1/(\rho(1-\rho)\ln q)\). Since this bound does not depend on \(\delta\), it seems that further improvements might be possible.

An example plot of all the bounds is provided in figures 1 and 2. Since the improvements for larger \(q\) are weak for \(q = 16\). In figure 1 the first plot is obtained at a particular value of \(\delta\) and the second plot is obtained at a particular value of \(\rho\). The improvements (over LP) are obtained in the regions \(0.536 \leq \rho \leq 0.67\) and \(0.60 \leq \delta \leq 0.774\), respectively. Figure 2 shows the plots when \(q\) is increasing with \(n\). In this case, we compare against the Singleton upper bound. It shows improvements in the region \(\rho \leq \delta \leq 3/2\rho\). Construction of codes which meet this upper bound for any parameters is an open problem.

Remarks:

1. For \(q > n\) and \(r = 1\), Dukes [12] provides a Singleton bound, \(A_q^{SW}(n, d, 1) \leq (q-1) \cdots (q-n+d)\). Not surprisingly, for \(q = \theta n, \theta > 1\) this reduces to \(1 - \delta\) in the asymptotics.

2. Missing from the list of bounds above is a Hamming-type bound on the symbol weight codes. The lack of a simple expression for the size of the ball is the main reason behind this omission.

V. LOWER BOUND ON SYMBOL WEIGHT CODES

As mentioned in the previous sections, the traditional means of determining the GV-type bounds is not very useful for non-asymptotic block lengths \(n\). In this section we adopt a different approach to determine lower bounds on the size of symbol weight codes. The lower bounds are obtained by using corresponding constructions and lower bounds on constant
composition codes. There is a wide body of literature on
CCCs that can be used to determine these lower bounds; see
[3,16]. To the best of our knowledge, most of the work
in the literature on constant composition codes has focused
on determining constructions and bounds for either very large
distances (in the region where the Johnson bound or Plotkin
bound is applicable) or for very small distances such as
d = 2, 3, 4. For FPA and permutation codes, there do exist
constructions with distances in the ranges in between; see [4,8,15]. We note three papers in this connection. Sidorenko
[28] provides an asymptotic upper bound on CCCs; this is not
useful for this section since we look at lower bounds. In a very
recent work, Luo and Helleseth [23] construct CCCs of almost
uniform composition and with relative distances very close to
the Plotkin limit (\( d/n \approx (q-1)/q \)). The bound that we provide
below requires a relatively large alphabet size so that codes
from different constant composition spaces can be combined.
Hence, the CCCs from [23] are not useful in this context.
Chu et al. [8] provide some lower bounds for CCCs for large
distances. We use some of the constructions from this latter
work in this section to provide examples of lower bounds on
symbol weight codes.

We first describe a method to determine the size of a symbol
weight code in terms of CCCs. This method may be viewed as
a generalization of an elementary bound in Bachoc et al. [3]
Equation (2) on binary bounded weight codes to \( q \)-ary spaces.

Let \( \mathbf{n} = [n_0, \ldots, n_{q-1}] \) and \( \mathbf{n}' = [n_0', \ldots, n_{q-1}'] \) denote
two different compositions of \( n \). The aim here is to lower
bound the size of a symbol weight code by the sum of
all possible different CCCs which have the same symbol
weight. Thus, we first need to determine the condition on two
different compositions \( \mathbf{n} \) and \( \mathbf{n}' \) such that any vector \( e \) with
composition \( \mathbf{n} \) is at least distance \( d \) away from a vector \( e' \)
with composition \( \mathbf{n}' \). It can be seen that \( \min\{n_i, n_i'\} \) is the
maximum number of coordinates in \( e \) and \( e' \) where the \( i \)-th
symbol is common to both. Thus, the Hamming distance
\( d_H(e, e') \) satisfies

\[
d_H(e, e') \geq n - \sum_{i=0}^{q-1} \min\{n_i, n_i'\}.
\]

A sufficient condition for \( d_H(e, e') \geq d \) to hold is

\[
n - \sum_{i=0}^{q-1} \min\{n_i, n_i'\} \geq d. \tag{9}
\]

Let

\[
d_+(\mathbf{n}, \mathbf{n}') \equiv n - \sum_{i=0}^{q-1} \min\{n_i, n_i'\}. \tag{10}
\]

Then we obtain

**Lemma 5.1:** \( d_+(\cdot, \cdot) \) is a distance function on \( \mathcal{N} \).

**Proof:** \( d_+(\mathbf{n}, \mathbf{n}') \) is clearly symmetric. To show the
triangle inequality, we note that we can rewrite

\[
d_+(\mathbf{n}, \mathbf{n}') = \sum_{i=0}^{q-1} n_i \min\{n_i, n_i'\} = \sum_{i} (n_i - n_i')^+,
\]

where \( (x)^+ \equiv \max\{x, 0\} \). Also, for any non-negative real
numbers \( x, y, z \), it can be readily verified that

\[(x - y)^+ + (y - z)^+ \geq (x - z)^+.
\]

Thus, we get

\[
d_+(\mathbf{n}, \mathbf{n}') + d_+(\mathbf{n}', \mathbf{n}'') = \sum_{i} (n_i - n_i')^+ + \sum_{i} (n_i' - n_i'')^+ = \sum_{i} (n_i - n_i')^+ + (n_i' - n_i'')^+ \geq \sum_{i} (n_i - n_i'')^+ = d_+(\mathbf{n}, \mathbf{n}'').
\]

Since \( (n_i - n_i')^+ \geq 0 \), we get that \( d_+(\mathbf{n}, \mathbf{n}') = 0 \) if and only
if \( n_i = n_i' \) for all \( i = 0, \ldots, q - 1 \). \( \blacksquare \)

Let \( \mathcal{N}(r, d) \subset \mathcal{N}(r) \) (resp. \( \mathcal{N}(\leq r, d) \subset \mathcal{N}(\leq r) \)) be such
that for any distinct \( \mathbf{n}, \mathbf{n}' \in \mathcal{N}(r, d) \) (resp. \( \mathcal{N}(\leq r, d) \)) we have

\[
\text{Fig. 2. Plots for } \delta = 2/3 \text{ and for } \rho = 0.6, \text{ respectively.}
\]
We now readily give a lower bound on the size of symbol weight codes in terms of the CCCs:

\[
A_q^{SW}(n, d, r) \geq \sum_{n \in N(r, d)} A_q(n, d), \\
A_q^{SW}(n, d, \leq r) \geq \sum_{n \in N(\leq r, d)} A_q(n, d).
\]  

For large \( n \) and \( q \) the size of the set \( N(r) \) becomes very large. Hence finding all the compositions in \( N(r) \) which are separated by distance at least \( d \) is difficult. We instead seek lower bounds on \( N(r, d) \) so that the size of the symbol weight codes can be more easily expressed in terms of the sizes of either one or a few CCCs.

**Remark:** Note that \( d_+(\cdot, \cdot) \) is a metric on a “simplex” which intersects each axis at (Euclidean) distance \( n \) from the origin. In particular, the components of \( n \) need not be restricted to integers for \( d_+(\cdot, \cdot) \) to become a metric. Also, \( n \) need not be restricted to be an integer.

### A. Lower bounds on \( |N(r, d)| \)

In this section we determine lower bounds to the size of \( N(r, d) \). To get these lower bounds, we first obtain a relation between the Hamming distance between two compositions and the distance between two compositions as given by [10].

**Lemma 5.2:** For any two compositions \( n, n' \in N \), if \( d_H(n, n') = 2d \) then \( d_+(n, n') \geq d \).

**Proof:** Define two sets \( I^+ = \{ i : n_i > n'_i \} \) and \( I^- = \{ i : n_i < n'_i \} \). Clearly, in the rest of the coordinates, \( n_i = n'_i \). Then we get the following set of equalities.

\[
\sum_{i=0}^{q-1} n_i = \sum_{i=0}^{q-1} n'_i \\
\Leftrightarrow \sum_{i \in I^+} n_i + \sum_{i \in I^-} n_i = \sum_{i \in I^+} n'_i + \sum_{i \in I^-} n'_i \\
\Leftrightarrow \sum_{i \in I^+} (n_i - n'_i) = \sum_{i \in I^-} (n'_i - n_i) \\
\Leftrightarrow \sum_{i \in I^+ \cup I^-} (n_i - n'_i) = \sum_{i \in I^+ \cup I^-} (n'_i - n_i). \tag{12}
\]

Note that the LHS and RHS of the last equation are both equal to \( d_+(n, n') \). Let \( |I^+| = x \), then since \( d_H(n, n') = 2d \), we get \( |I^-| = 2d - x \). Using the fact that the difference \( n_i - n'_i \geq 1 \), for \( i \in I^+ \) and \( n'_i - n_i \geq 1 \) for \( i \in I^- \), we get

\[
d_+(n, n') \geq \max\{x, 2d - x\} \\
\geq \min_{1 \leq x \leq 2d - 1} \max\{x, 2d - x\} \\
= d.
\]

This lemma immediately allows us to use existing GV bounds in various spaces (under Hamming distance) to derive lower bounds on \( |N(r, d)| \).

1) **Lower bound from a permutation code on \( S_r \):** Let the alphabet set be \( \{0, \ldots, r-1\} \), that is, \( q = r \). In every word of length \( n = r(r+1)/2 \), let all the \( r \) symbols occur such that the frequencies of the symbols are in the set \( \{1, \ldots, r\} \) and all the frequencies occur. Because of this construction, given \( r \) the values of \( n, q \) are restricted as given above. Using the GV lower bound on the permutation code with Hamming distance at least \( 2d \) between two codewords gives us the lower bound

\[
|N(r, d)| \geq \frac{r!}{V(2d - 1, S_r)}, \tag{13}
\]

where \( V(2d - 1, S_r) \) is the volume of the ball of radius \( 2d - 1 \) in \( S_r \).

2) **Lower bound for general \( q \):** As explained in the proof of Theorem [13] a lower bound on constant symbol weight codes is provided by an Elias-type bound in the Hamming space. We can obtain another lower bound on constant symbol weight codes by considering lower bounds on \( N(r, d) \). A lower bound on \( N(r, d) \) is obtained by letting \( k \) of the symbols \( \{0, \ldots, q-1\} \) repeat \( r \) times in every codeword of the constant symbol weight code and the remaining \( q - k \) symbols satisfy the condition that there are \( (q-k)\{\frac{n-rk}{q-k}\} \) symbols with composition \( l_1 = \lceil \frac{n-rk}{q-k} \rceil \) and \( (q-k)(1-\{\frac{n-rk}{q-k}\}) \) symbols with composition \( l_0 = \lfloor \frac{n-rk}{q-k} \rfloor \).

Denote this composition by \( n = (l_0, l_1, k, r) \), that is,

\[
n(l_0, l_1, k, r) = (r, \ldots, r, l_0, \ldots, l_0, l_1, \ldots, l_1). \tag{13}
\]

Because of the above choice of the repetitions of each symbol we seek a “binary constant weight code” in \( N(r, d) \) where \( q-k \) coordinates have the value \( l_0 \) or \( l_1 \) and the rest \( k \) coordinates have the value \( r \). We also want the Hamming distance between distinct codewords to be at least \( 2d \). Denote the maximum size of a binary constant weight code of length \( n \), weight \( w \) and minimum distance \( d \) by \( A_2(n, d, w) \).

The GV bound under the above constraints is

\[
|N(r, d)| \geq A_2(q, 2d, k) \geq \left( \frac{q}{k} \right)^2 \left( \binom{q}{k} \right)^{-\frac{2d-2}{k}} \left( \binom{q}{k} \right)^{-\frac{2d-2}{k}}.
\]

Note that we get \( 2d - 2 \) in the denominator (instead of \( 2d - 1 \)) since the binary constant weight space affords only even distances. From Levenshtein [13] we know that the lower bound is significant and grows exponentially as \( 2^q T \), for some constant \( T = T(q, k, d) \) only when the following conditions are satisfied

\[
\frac{q}{2} \left( 1 - \sqrt{1 - \frac{4d}{q}} \right) \leq k \leq \frac{q}{2} \left( 1 + \sqrt{1 - \frac{4d}{q}} \right),
\]

\[
d \leq k \left( 1 - \frac{k}{q} \right).
\]

The above lower bounds on \( |N(r, d)| \) give lower bounds on symbol weight codes as follows.

### B. Lower bounds on codes

The lower bound on \( A_q^{SW}(n, d, r) \) can be stated as follows.
Theorem 5.3: We get the following results for different compositions.

1) For \( n = [1, \ldots, r] \), we get
\[
A_q^{SW}(n, d, r) \geq \frac{r!}{V(2d - 1, S_r)} A_q(n, d).
\]

2) For \( n = n(0, l_1, k, r) \), we get
\[
A_q^{SW}(n, d, r) \geq A_2(q, 2d, k) A_q(n, d)
\]
\[
\geq \max_{k_0 \leq k \leq \lfloor n/r \rfloor} \sum_{i=0}^{b} A_2(q, 2d, k_i + 2di) \times A_q(n(l_0, l_1, k_i + 2di, r), d).
\]

3) Let \( k_1 \leq k_0 = \max\{n - (r-1)q, 1\} \), and \( b = b(k_1) = \left\lfloor \frac{n/r - k_1}{2d} \right\rfloor \). Then
\[
A_q^{SW}(n, d, r) \geq \max_{k_0 \leq k \leq \lfloor n/r \rfloor} \sum_{i=0}^{b} A_2(q, 2d, k_i + 2di) \times A_q(n(l_0, l_1, k_i + 2di, r), d).
\]

Proof: The first two results follow immediately from the lower bounds on \( |N(r, d)| \). In part 1, each codeword in the permutation code corresponds to a rearrangement of the composition \( n = [1, \ldots, r] \). In part 2, each codeword in the binary constant weight code corresponds to a rearrangement of the composition \( n = n(l_0, l_1, k, r) \).

The third result, we include a larger range of CCCs. The expression is obtained by taking constant composition codes from separate constant composition spaces \( n(l_0, l_1, k_1 + 2di, r) \), whose compositions are separated by a Hamming distance of at least \( 2d \). Two different compositions \( n(l_0, l_1, k_1 + 2di, r) \) and \( n(l_0, l_1, k_1 + 2di + 1, r) \) correspond to taking binary constant weight codes with weights separated by \( 2d \). Note that this choice of separate compositions corresponds to a binary bounded weight code, as studied in [3].

There is a trade-off between the size of the constant composition space with composition \( n(l_0, l_1, k, r) \) and the size of the constant weight code in \( \mathbb{Z}_2^n \). The size of the constant weight code in \( \mathbb{Z}_2^n \) is substantial only for large \( k \) around \( q/2 \). On the other hand, the size of the constant composition space is large for small \( k \), thus potentially allowing for a larger CCC.

The lower bound in equation (14) is in fact useful in the case of a bounded symbol weight code with symbol weight at most \( r \). It is unclear how to combine codes of different symbol weights \( s \), where \( \lfloor n/q \rfloor \leq s \leq r \), such that we can obtain a computable expression. We instead use equation (14) and optimize over the different symbol weights \( s \) and the smallest weight \( k_1 \). Note that for a given symbol weight \( s \), the quantity \( k_1 \) corresponds to the minimum number of symbols with frequency \( s \) that we include in our estimate.

Theorem 5.4:
\[
A_q^{SW}(n, d, \leq r) \geq \max_{\lfloor \frac{n}{q} \rfloor \leq s \leq r} A_q^{SW}(n, d, s)
\]
\[
\geq \max_{\lfloor \frac{n}{q} \rfloor \leq s \leq r} \max_{k_1 \leq k \leq \lfloor \frac{n}{s} \rfloor} \sum_{i=0}^{b(s)} A_2(q, 2d, k(i, s))
\]
\[
\times A_q(n(l_0(i, s), l_1(i, s), k(i, s), s), d),
\]
where \( k_1 \equiv k_1(s) \geq \max\{n - (s-1)q, 1\}, k \equiv k(i, s) = k_1(s) + 2di, b(s) = \left\lfloor \frac{n/s - k_1}{2d} \right\rfloor \), \( l_0(i, s) = \left\lceil \frac{n - sk_1}{q - s} \right\rceil \), and \( l_1(i, s) = \left\lfloor \frac{n - sk_1}{q - s} \right\rfloor \).

C. Numerical examples

We consider some numerical examples in order to show how the expressions in the previous section can be used to obtain lower bounds on symbol weight codes. We adopt the exponential notation of Chu et al. [8] to denote a composition in a compact form. The notation \( n_0^{n_1} n_0 \cdots n_{q-1}^{n_q-1} \) is used to denote the composition
\[
[n_0, \ldots, n_0, n_1, \ldots, n_1, \ldots, n_{q-1}, \ldots, n_{q-1}].
\]

We also recall the notion of a refinement of a composition from the same work. The composition \( n = [n_0, \ldots, n_{q-1}] \) is called a refinement of a composition \( m = [m_0, \ldots, m_{p-1}] \) if there is a partition \( \mathcal{I}_0, \ldots, \mathcal{I}_p \) of \( \{0, \ldots, q-1\} \) such that \( \sum_{i \in \mathcal{I}_j} n_i = m_j \), for every \( j \). We write \( n \preceq m \) if \( n \) is a refinement of \( m \). This notion is important because of the following inequality (see [8]):
\[
A_q([n_0, \ldots, n_{q-1}], d) \geq A_p([m_0, \ldots, m_{p-1}], d).
\]

Below, we use lower bounds on FPAs, where the lower bound is taken from [8]. Using equation (15), lower bounds on CCCs are obtained from the lower bounds on the FPAs. The lower bound on FPA mentioned below rely on the existence of certain (generalized) distance preserving mappings from \( \mathbb{Z}_q^n \) to the permutation space \( S_n \) (see [8]). The distances between compositions used in this section are all taken in the \( d_+(\cdot, \cdot) \) metric, unless mentioned otherwise.

Example 5.5: In this example we show how Theorem 5.3 and equation (11) can be used. We know from Example 3.7 that \( A_0(6^4, 7) \geq 2^{12} \). Since \( 14^4 < 6^4 \), we immediately obtain that \( A_0(14^4, 7) \geq 2^{12} \). In this case, \( q = 8 \) and \( d = 7 \) and the number of symbols occurring with frequency \( 5 \) is \( k = 4 \). Hence Theorem 5.3 is not applicable. But equation (11) can be applied directly. For instance the compositions \( 1^5 5^4 \) and \( 5^4 1^5 \) satisfy \( d_+(1^5 5^4, 5^4 1^5) = 4(1 - 5)^+ + 4(5 - 1)^+ = 16 \) which is greater than 7. Thus, \( A_3^{SW}(24, 7, 5) \geq 2 \cdot 2^{12} \).

In fact, the compositions \( n = 1^4 5^4 \) and \( n' = 5^4 1^4 \) have the special property that if a symbol \( i \) has different compositions \( n_i, n_i' \) then \( |n_i - n_i'| = 4 \). We can exploit this property to get a variant of Lemma 5.5 below.

Lemma 5.6: For two compositions \( n, n' \in N \), let \( d_H(n, n') = D \). For \( i = 0, \ldots, q-1 \), if either \( |n_i - n_i'| \geq a > 0 \) or it is zero, then \( d_+(n, n') \geq Da/2 \).

Proof: The proof is very similar to the proof of Lemma 5.5. Let \( I^+, I^- \) be as defined in the proof of that lemma, and let \( |I^+| = x, |I^-| = D - x \). Finally, use equation (12) to get
\[
d_+(n, n') \geq a \max\{x, D - x\}
\]
\[
\geq a \min_{1 \leq x \leq D - 1} \max\{x, D - x\} \geq Da/2.
\]
Example 5.7: Returning to the previous example and a finer refinement $1^{2^8} \prec 6^4$. We show in this example that directly using equation (11) can lead to a better bound, compared to Theorem 5.3. In this case, we apply Theorem 5.3 with $k = 8$, $2d = 14$, $q = 16$, and $n(0,1,k,r) = 1^{6^2}$. From the table of constant weight codes in [1], we get $A_2(16,14,8) = 2$. This gives $A^C_{16}(24,7,2) \geq 2 \cdot 2^{12}$. However, this bound can be improved by using equation (11).

A greedy search through the compositions with the maximum value of each part being 2, shows that the compositions $(0,0,1,2,0,1,2,0,2,1,2,0,1,2,0,2,1,2)_{16}$ are mutually at distance at least 7 from one another. Since each of them is a refinement of $6^4$ we get that $A^C_{16}(24,7,2) \geq 5 \cdot 2^{12}$.

Finally, we look at an example which considers the bounded symbol weight and demonstrate the use of Theorem 5.4.

Example 5.8: Consider the refinement $3^8 \prec 6^4$. We can consider a code in this space to be embedded in the constant composition space with 16 symbols. Thus, we get $A_{16}(3^0 8^6,7) \geq 2^{12}$. We use the fact that if we consider all compositions containing 8 symbols occurring with frequency 3, then the difference of frequency between two symbols from different compositions is either 0 or 3. Thus, $a = 3$, $k = 8$, and $q = 16$. Using Lemma 5.6 we need to ensure that $Da/2 \geq 7 \Rightarrow D \geq 5$. We get the lower bound $A_{16}(24,7,3) \geq A_{16}(24,5,8) \geq 2^{12} \cdot 2^{12}$. From (11) we have $A_{16}(24,5,8) = A_{16}(24,6,8) \geq 120$. Hence, $A^C_{16}(24,7,3) \geq \max\{A^C_{16}(24,7,3), A^C_{16}(24,7,2)\} \geq 120 \cdot 2^{12}$. In this particular example, using the lower bound in equation (14) on the constant symbol weight codes with $k_1 = 1$ does not yield a better bound, primarily due to the absence of a known good lower bound on the corresponding CCC. The improvement mainly stems from the fact that we use a large binary constant weight code with weight $k_1 = q/2$.

As is evident from the above examples, Theorems 5.3 and 5.4 help in actual computation of the bounds. In Example 5.7, the number of ordered partitions of $n = 24$, into $q = 16$ parts with each part taking values between 0 and 2, inclusive, is $|P(24,16,2)| = 258570$. A non-exhaustive greedy search could only find 5 compositions. It is computationally difficult to search exhaustively in such a large space. Similarly, for larger lengths and alphabet sizes, finding the size of, and compositions in, $N(r,d)$ is difficult. Instead, by relying on known bounds on binary constant weight codes and CCCs, we compute the sizes of the symbol weight codes more easily.

VI. Constructions of Symbol Weight Codes

In this section we determine constructions of symbol weight codes. Versfeld et al. [29, 30] provided constructions of bounded symbol weight codes from Reed-Solomon codes. We seek to obtain constant symbol weight codes with positive rate and positive relative distance. The following two constructions provide us with such codes with positive rate and positive relative distance, given that we already have a constant symbol weight code with positive rate and positive relative distance.

$u|v$ construction: Let $C$ be a constant symbol weight code with parameters $C(n,M,d,r)_q$ over $\mathbb{Z}_q$. Let $C'$ be an FPA over $\mathbb{Z}_q$ with parameters $C'(r'q,M',d')$. Then the $u|v$ construction results in a code $D$. It is obtained by taking all codewords as follows:

$$D = \{(u,v): u \in C, v \in C'\}.$$ 

The code $D$ has parameters $D(n+r'q,MM',\min\{d,d'\},r+r')_q$ over $\mathbb{Z}_q$. In particular if the code $C$ had the minimum symbol weight $r = \lfloor n/q \rfloor$ then so does the code $D$, that is, $r+r' = \lfloor (n+r'q)/q \rfloor$.

Concatenated construction: Let $C$ be a code over $\mathbb{Z}_q$ with parameters $C(n,M,d)_q$. Let $C'$ be an FPA with parameters $C'(r'q,M',d')_p$ over $\mathbb{Z}_p$, such that $M' \geq q$. The concatenated code $D$ with $C'$ as the inner code and $C$ as the outer code has parameters $D(nrp,M,dd',rn)_p$. It is obtained by replacing every $q$-ary symbol of $C$ with a codeword from $C'$. In particular, the resulting code $D$ has the minimum symbol weight $npr/p = nr$.

A. Constructions from Reed-Solomon Codes

In this section, we use the symbol $k$ to denote the dimension of the Reed-Solomon code. Let $C[n,k,d]_q$ be a Reed-Solomon code over a finite field $\mathbb{F}_q$ with $d = n - k + 1$ and $n = q - 1$. Versfeld et al. [29, 30] showed that aside from the Reed-Solomon codewords which correspond to a constant polynomial, the Reed-Solomon code has maximum symbol weight of $n - d = k - 1$. It is also established in the same works that there exists a coset of the Reed-Solomon code such that the maximum symbol weight of any codeword in the code is at most $n - d + 1$. These codes belong to the bounded symbol weight space $SW(n,q,\leq r)$. By the Singleton bound, these are optimal codes.

In this section we establish several results which show that subsets of Reed-Solomon codes or their cosets can achieve the GV-type lower bound in Theorem 4.3. First, Lemma 6.1 below shows that for any constant symbol weight $r$, there exists a coset of the Reed-Solomon code that attains the GV bound asymptotically. In Theorem 6.3 we provide a more explicit description of a subset of the Reed-Solomon code itself that has the constant symbol weight $r$ for $r \geq n/2$, such that it attains the GV bound asymptotically. Since $k - 1 \geq r$, this also means that this latter result holds only for Reed-Solomon codes with rate more than 1/2.

We first show by an averaging argument that the GV bound can be achieved by subcodes of cosets of Reed-Solomon codes.

Lemma 6.1: Let $C[n,k,d]_q$ be a family of Reed-Solomon codes.

For $n \rightarrow \infty$ let $r/n \rightarrow \rho$, and $d/n \rightarrow \delta$. Then there
exists a family of subcodes $\mathcal{C}'$ which is a subset of some coset of the code $\mathcal{C}$ such that
\[
\liminf_{n \to \infty} \frac{1}{n} \log_q |\mathcal{C}'| \geq 1 - \rho - \delta.
\]

**Proof:** Let $\mathcal{C}_1, \ldots, \mathcal{C}_{q^{n-k}}$ denote the cosets of the Reed-Solomon code. Since the cosets of the Reed-Solomon code are disjoint and they partition the Hamming space, we have
\[
\sum_{i=1}^{q^{n-k}} |\mathcal{C}_i \cap SW(n, q, r)| = |SW(n, q, r)|.
\]
Thus, the average size of the intersection of a coset with the space $SW(n, q, r)$ is $|SW(n, q, r)|/q^{n-k}$. Hence, there exists at least one coset whose intersection with $SW(n, q, r)$ has size at least this average. In the asymptotics for $n, q \to \infty$, we get the result stated in the Lemma.

In the remaining part of this section, we give a more explicit description of a subcode of the Reed-Solomon code with rate equal to the GV-type bound. The derivation of this result uses a lemma and a proposition stated below. The Proposition 6.2 below states that asymptotically the rate of the constant symbol weight code with symbol weight $r$ that is a subset of the Reed-Solomon code, can not exceed the rate of the subcode formed by all the codewords of weight $n - r$. Lemma 6.3 gives an upper bound on the size of the number of codewords of weight $n - r$. The combination of this proposition and the lemma imply that the rate of the constant symbol weight code, which is a subset of the Reed-Solomon code, with symbol weight $r = \rho n$, can not exceed the GV-type lower bound $1 - \rho - \delta$ that we obtained in Theorem 4.3, for any $\rho, 0 < \rho < 1$. Theorem 6.4 below shows that this rate can be attained for any $\rho$ satisfying $1/2 \leq \rho < 1$. We state the proposition and the lemma first, and defer their proofs to after the proof of the theorem.

**Proposition 6.2:** Let $\mathcal{C}[n, k, d]_q$ be a family of Reed-Solomon codes with parameters $n = q - 1, d = n - k + 1$. Let $S(r)$ denote the set of vectors with symbol weight exactly $r$, for $1 \leq r \leq k - 1$, and let $B_{n-r}$ denote the number of vectors of weight $n - r$. Then,
\[
|S(r)| \leq q(q-1)B_{n-r}.
\]

**Lemma 6.3:** The weight distribution $\{B_w : w = d, \ldots, n\}$ of a linear Maximum Distance Separable (MDS) code with parameters $[n, k, d]_q$ satisfies:
\[
B_{n-r} \leq \left( \frac{n}{n-r} \right) (q^{k-r} - 1),
\]
for $0 \leq r \leq k - 1$.

The main theorem in this section is now stated below.

**Theorem 6.4:** Let $\mathcal{C}[n, k, d]_q$ denote the family of Reed-Solomon codes with $n = q - 1$ and $d = n - k + 1$. Let $k - 1 \geq r \geq n/2$. For $n \to \infty$, let $r/n \to \rho$ and $d/n \to \delta$. There exists a family of subcodes $\mathcal{C}'$ of $\mathcal{C}$ of symbol weight exactly $r$ such that
\[
\lim_{n \to \infty} \frac{1}{n} \log_q |\mathcal{C}'| = 1 - \rho - \delta.
\]

**Proof:** Every codeword of the Reed-Solomon code consists of coordinates which are the evaluations at all the non-zero points of $F_q$, of a polynomial of degree at most $k - 1$. Let $f(x) = f_0 + f_1 x + \cdots + f_{k-1} x^{k-1}$ be a polynomial in $F_q$. Let $F_q = F_q \setminus \{0\}$. If $f(x)$ has symbol weight $r$ then it implies that $f(x) = \alpha$ for some $\alpha \in F_q$ and for $r$ different values of $x$ in $F_q^*$. In other words, $f(x) - \alpha$ has exactly $r$ distinct roots. Note that $r$ is restricted to be $r \leq k - 1$ since the polynomials can not have more than $k - 1$ roots.

Let $f(x)$ be a polynomial of degree $k - 1$ such that it has exactly $r$ nonzero distinct roots $\alpha_1, \ldots, \alpha_r$ in $F_q^*$. Then $f(x)$ can be written as
\[
f(x) = \beta(x - \alpha_1) \times \cdots \times (x - \alpha_r) \times g(x),
\]
where $\beta \in F_q^*$ and $g(x)$ is a product of monic irreducible polynomials, each of degree at least 2. The total degree of $g(x)$ is $k - 1 - r$. Since $r \geq n/2$, the polynomial $f(x)$ can not attain the value $\alpha$, where $\alpha \in F_q^*$, at more than $r$ different points $x \in F_q^*$ since there are $q - 1 - r \leq n/2$ points at which the function is nonzero. Hence, the symbol weight of the codeword represented by $f(x)$ is exactly $r$. We seek the asymptotic exponent of the number of such polynomials $f(x)$. This number is dominated by the number of possible monic irreducible polynomials $g(x)$. To describe this number, we recall the definition of the Môbius function $\mu(t)$,
\[
\mu(t) \triangleq \begin{cases} 
1, & \text{if } t = 1, \\
(-1)^s, & \text{if } t \text{ has } s \text{ distinct prime factors}, \\
0, & \text{if } p^2 | t \text{ for some prime } p.
\end{cases}
\]
The number of monic irreducible polynomials of degree $t$ is given by the sum $\frac{1}{2} \sum_{|s| \geq 1} \mu(s) q^{t/s}$ (see Lidl and Niederreiter [20 Theorem 3.25]). In particular, for large $t$, this sum is dominated by just the first term $\frac{1}{2} \mu(1) q^t = \frac{1}{2} q^t$. As a consequence, asymptotically the number of polynomials $f(x)$ of degree $k - 1 - r$. The asymptotic exponent of this count is approximately $\lim_{n \to \infty} (k - 1 - r)/n = 1 - \delta - \rho$. Thus the subset $\mathcal{C}'$ of $\mathcal{C}$ consists of all the codewords obtained from at least these polynomials. Hence the count above provides a lower bound on the rate of $\mathcal{C}'$:
\[
\liminf_{n \to \infty} \frac{1}{n} \log_q |\mathcal{C}'| \geq 1 - \delta - \rho.
\]
The upper bound on the rate of $\mathcal{C}'$ is obtained by applying both Lemma 6.3 and Proposition 6.2. We get
\[
|\mathcal{C}'| \leq |S(r)| \leq q(q-1)B_{n-r} \leq q(q-1) \left( \frac{n}{n-r} \right) q^{k-r},
\]
and,
\[
\limsup_{n \to \infty} \frac{1}{n} \log_q |S(r)| \leq \lim_{n \to \infty} \frac{k-r}{n} = 1 - \delta - \rho.
\]

**Proof of Proposition 6.2:** Let $c = (c_1, \ldots, c_n)$ be a codeword in the Reed-Solomon code. Then $c$ is the image of a polynomial $c(x)$ evaluated at all points of $F_q^* = F_q \setminus \{0\}$. 

We write \( c = (c(x))_{x \in \mathbb{F}_q^*} \). If \( c \) resulting from \( c(x) \) has symbol weight exactly \( r \) then so do the codewords obtained from the polynomials \( \gamma c(x) + \beta \), for \( \gamma \in \mathbb{F}_q^*, \beta \in \mathbb{F}_q \). Consider the subset \( S'(r) \) of \( S(r) \) that is obtained by retaining exactly one monic polynomial from the set \( \{ \gamma c(x) + \beta : \gamma \in \mathbb{F}_q^*, \beta \in \mathbb{F}_q \} \) for any polynomial \( c(x) \). Thus, the size of \( S'(r) \) satisfies \( |S'(r)| = |S(r)|/(q(q-1)) \).

We claim that \( |S'(r)| \leq B_{n-r} \). To show this, we claim that there exists an injection mapping from \( S'(r) \) to the set of all vectors of weight \( n-r \). Since any \( c(x) \) in \( S'(r) \) has symbol weight exactly \( r \), there exists a \( \beta \in \mathbb{F}_q \) such that \( c(x) - \beta \) has exactly \( r \) distinct roots. Thus, the codeword \( (c(x)- \beta)_{x \in \mathbb{F}_q^*} \) has Hamming weight exactly \( n-r \). This is the only such vector. If there exists \( e(x) \in S'(r) \) and \( \alpha \in \mathbb{F}_q \) such that \((e(x) - \alpha)_{x \in \mathbb{F}_q^*} = (c(x) - \beta)_{x \in \mathbb{F}_q^*} \), then the two polynomials \( c(x) \) and \( e(x) \) must satisfy the relation \( c(x) - \beta = e(x) - \alpha \) since they are the same on \( n = q-1 \) points and their degrees are at most \( k-1 < n \). Thus, \( c(x) = e(x) - \alpha + \beta \), which is not possible since \( S'(r) \) contains exactly one polynomial of this form.

**Proof of Lemma 6.3:** The expression for the weight distribution satisfies (see [24] Chapter 11):

\[
B_{n-r} = \binom{n}{n-r} \sum_{j=0}^{k-r-1} (-1)^j \binom{n-r}{j} (q^{k-r-j}-1).
\]

Retaining only the first term gives the required upper bound on \( B_{n-r} \). The above expression can be rewritten as

\[
B_{n-r} = \binom{n}{n-r} \left( (q^{k-r}-1) - \sum_{i=1}^{\lfloor (k-r-1)/2 \rfloor} \binom{n-r}{2i-1} \right) \times \left( (q^{k-r-2i-1}) - \binom{n-r}{2i} \right) \] 

\[
= I(2 \lfloor k-r-1 \rfloor) \binom{n-r}{k-r-1} (q-1),
\]

where \( I(2 \lfloor k-r-1 \rfloor) \) is an indicator function that is 1 if 2 does not divide \( k-r-1 \) and 0 otherwise. We show that each of the terms in the summation above is positive and hence we can upper bound \( B_{n-r} \) by only the first term. This is proved via the following sequence of inequalities. For any \( j, j = 0, \ldots, k-r-1 \), we have

\[
\binom{n-r}{j} (q^{k-r-j}-1) > \binom{n-r}{j+1} (q^{k-r-j-1}-1) 
\]

\[
\Leftrightarrow q^{k-r-j} - 1 > \frac{n-r-j}{j+1} q^{k-r-j-1} - 1 
\]

\[
\Leftrightarrow q > \frac{n-r-j}{j+1} \frac{1-q^{-(k-r-j)}}{1-q^{-(k-r-j-1)}}.
\]

We use the inequality \( q > (n-r)/(1-q^{-1}) \). This expression is greater than the RHS of the above because of the inequalities \( 1 - q^{-1} \leq 1 - q^{-(k-r-j)} \), \( 1 \geq 1 - q^{-(k-r-j-1)} \), and \( n-r \geq (n-r-j)/(j+1) \). This proves the lemma.

**B. Discussion**

For correcting narrowband noise in the powerline channel, it is desirable that the symbol weight be close to the minimum possible value of \( [n/q] \). It remains open to determine a large subset of the Reed-Solomon code for the case \( \rho < 1/2 \). It follows from Proposition 6.2 that the rate of this subset can not exceed the GV-type bound \( 1-\rho-\delta \). The more interesting question is whether this bound can be achieved, especially in the cases where \( r \) is small. The work of Konyagin and Pappalardi [17] gives an affirmative answer to this question in the case of \( r = 1 \), and for low relative distance \( \delta \). They show that the number of permutation polynomials of degree at most \( q-1-d \) is approximately \( q^d/d! \) for \( d = 0.03983q \). This is asymptotically, \( 1/q \log_q(q^d) \leq 1-\delta \), where \( \delta = 0.001n \).

For the other ranges of \( r \), \( r \) is growing with \( n \), we believe that it should be possible to attain the GV bound. For instance, it would be interesting to prove that for large \( r \), \( r \geq (k-1)/2 \), and for any irreducible polynomial \( g(x) \) of degree \( k-r-1 \), there exists \( r \) distinct and nonzero points \( \alpha_1, \ldots, \alpha_r \) in \( \mathbb{F}_q^* \) such that the polynomial \( (x-\alpha_1) \cdots (x-\alpha_r)g(x) \) has symbol weight exactly \( r \). Since most of the count of polynomials attaining constant symbol weight \( r \) comes from the count of irreducible polynomials, proving this will show that the rate attains the GV-type bound. We have obtained no counterexample on performing an exhaustive computer search over all such irreducible polynomials \( g(x) \) of degree \( k-r-1 \), with \( (k-1)/2 \leq r < k < n \) in all finite fields up to \( \mathbb{F}_{17} \). We are unable to verify for larger fields because the computations become prohibitive. We believe that the conjecture is not true for very small \( r \) (when \( r \) does not grow with \( n \)). For instance for \( r = 1 \) the polynomial \( (x-\alpha)g(x) \), where \( g(x) = x^2 + 2 \) is an irreducible polynomial in \( \mathbb{F}_q^* \), has symbol weight greater than \( 1 \) for every choice of \( \alpha \in \mathbb{F}_q^* \).

**VII. Conclusion**

We derive the asymptotic estimates of the sizes of symbol weight codes. We also provide means of obtaining lower bounds on such codes and show that it is possible to provide symbol weight codes with the minimal possible symbol weight via recursive constructions, given we start with a known such code. Finally, we provided constructions of asymptotically good constant symbol weight codes. It remains open to determine families of codes with positive rate and positive relative distance with symbol weights that are optimal or close to the optimal value of \( [n/q] \).

**Acknowledgement**

We thank the Associate Editor Navin Kashyap for pointing out an error in an earlier version of the manuscript, and for his comments, which helped us improve the presentation of this article.
