Abstract

This paper describes the Sentence Planner (SP) in the HealthDoc project, which is concerned with the production of customized patient-education material from a source encoded in terms of plans. The task of the SP is to transform selected, not necessarily consecutive, plans (which may vary in detail, from text plans specifying only content and discourse organization to fine-grained but incohesive, sentence plans) into completely specified specifications for the surface generator. The paper identifies the sentence planning tasks, which are highly interdependent and partially parallel, and argues, in accordance with [Nirenburg et al., 1989], that a blackboard architecture with several independent modules is most suitable to deal with them. The architecture is presented, and the interaction of the sentence planning modules within this architecture is shown. The first implementation of the SP is discussed; examples illustrate the planning process in action.

1 Sentence Planning

1.1 Introduction

Most current models of text generation include a phase of content selection and organization, usually performed by a text planner or schema application engine, followed by a phase of grammatical surface-form rendering, performed by a sentence generator.

In practice, it is usually found that the sentence generator requires more detailed linguistic information than text planners or schema appliers can provide [Meteer, 1991; Rambow and Korelsky, 1992; Hovy, 1992; Panaget, 1994; Wanner, 1994]. So further planning is required. Following [Rambow and Korelsky, 1992], we call this additional planning task sentence planning (even though some operations may cross sentence boundaries). A sentence planner (SP) must specify one of the various possible alternative phrasings at roughly the sentence and clause level. By transforming and augmenting its input, the sentence planner produces representations detailed enough for the surface generator to operate deterministically. Consider an example where the lack of sentence planning results in an awkward text:

(0) In some instances, an implant wears out, loosens, or fails. If an implant wears out, loosens, or fails, it will have to be removed.

More appropriate alternatives can be generated when different sentence planning techniques are used:

(1) Alternative reference:
In some instances, an implant wears out, loosens, or fails. If this happens, it will have to be removed.

(2) Alternative lexical choice:
In some instances, an implant wears out, loosens, or fails. If replacement is needed, it will have to be removed.

(3) Removal of redundancy (aggregation):
In some instances, an implant wears out, loosens, or fails, and [...] will have to be removed.

In this paper we describe the sentence planner in the HealthDoc project. HealthDoc [DiMarco et al., 1995] was established in early 1995 with the goal of generating customized
patient-education documents. It combines existing generation technology—the sentence generator KPML [Bateman, 1995]¹ and its input notation SPL [Kasper, 1989]—and new systems, such as the sentence planner described here. The sentence planner embodies a design that we hope has some general applicability in bridging the gap between text planners and sentence generators. Its input is a specification of the desired output content (a patient document) written in Text Source Language (TSL), see Subsection 2.3; its output consists of one or more SPL expressions. Its general operation is to recombine, enhance, and refine TSL expressions until they are adequately specific SPL expressions.

1.1 Sentence Planning Tasks

After analysis of a number of patient-education documents, including those on diabetes, cholesterol, and hormone replacement therapy, we have identified the following most important sentence planning tasks:

- **Fine-grain discourse structuring:** Discourse relations (RST relations, for example) that conjoin clause-size pieces in the TSL are still open to considerable variation of expression, such as the inclusion of a discourse marker or the lexical or implicit communication of the discourse relation. See, for example, [Scott and de Souza, 1990] for treatment of ELABORATION, [Vander Linden and Martin, 1995] of PURPOSE, and [Grote et al., 1995] of CONCESSION.

- **Sentence grouping and sentence content determination:** Individual sentences must be delimited; temporal, spatial, and causal nuances of predicates must be determined, and so on [Meteer, 1991; Pustejovsky, 1995; Stede, 1996].

- **Clause-internal structuring:** The order of clause constituents, taxis, and projectivity of propositions within the clause [Hovy, 1992; DiMarco and Hirst, 1993; Panaget, 1994] must be determined; within each sentence, the thematized and focused elements must be identified [Iordanskaja, 1992]; redundancy must be removed [Dalianis and Hovy, 1996a; Dalianis and Hovy, 1996b].

- **Reference planning (endophoric lexical choice):** The particular form of coreference (including anaphora, deixis, and ellipsis) and reference must be chosen in order to maintain discourse cohesion [McDonald, 1978; Tutin and Kittredge, 1992; Dale and Reiter, 1995].

- **Exophoric lexical choice:** As argued in [Nirenburg et al., 1989; Meteer, 1991; Wanner, 1994], lexical choice other than linguistic reference should also be considered a sentence planning task, since lexical units predetermine the syntactic structure of a clause, and since salience may be realized by lexical means.

2 The Sentence Planner

2.1 Constraints and Desiderata

Given the nature of the task (namely, the transformation and/or augmentation of partial sentence specifications into full ones), a set of constraints emerge for the design of the Sentence Planner. We believe these constraints to be fairly general; that is, that sentence planners developed for applications other than HealthDoc will have much the same structure. These constraints are the following:

1. The SP must transform an underspecified input of deep semantics into a suitably specified output of shallow semantics.

2. The SP must modularize sentence planning tasks as far as possible, to facilitate design clarity, development, and maintenance. Since the sentence planning tasks listed above are not single-step operations, since they do not have to be performed in strict sequence [De Smedt, 1990; Reithinger, 1992], and since the planner's operation is non-deterministic (early choices may undergo subsequent revision), this suggests that each sentence planning task should be implemented by a separate module or by several modules.

3. The intermediate steps of the SP should be accessible and easily interpretable to people building the SP, to enable cross-module interconnection and debugging.

4. The SP must be extensible, allowing new modules to be introduced as a need for them is identified.

5. The level of sophistication of the knowledge within a module must not be constrained by the SP architecture, so that the modules might be crude initially but then can incrementally be
refined *without impeding throughput*. To facilitate this, the rules and knowledge resources employed by the SP modules should be represented as declaratively as possible.

Constraints 1 and 3 suggest that the intermediate form(s) of the data during SP operation be some sort of SPL-in-emergence; that is, a frame continually evolving from the more abstract input to the final SPL output(s). One way to achieve this is to see SP modules as tree-transformation engines (viewing SPL and pre-SPL expressions as trees\(^2\)). This means that their effects must be written as tree-rewriting rules in the following general form (see Section 2.3):

\[ \text{[pre-SPL}}_1 \rightarrow \text{pre-SPL}}_2 \]

Naturally, each module must know which tree transformation rule to apply to any given pre-SPL under any given conditions. A suitable mechanism is provided by system networks, used just as in KPML's grammar [Matthiessen and Bateman, 1991]. Each module contains a feature (system) network that discriminates arbitrarily finely to a desired state. At any point in the network, the selection of a feature with an associated tree-rewriting rule causes application of that rule to the current pre-SPL. Thus tree-rewriting rules are realization statements in the SP modules (several other realization operators are also supported).

Constraints 2, 4, and 5 suggest that the SP employ a blackboard architecture. As has already been argued by [Nirenburg et al., 1989], a blackboard is best suited to accommodate the flexible order in which modules can take action. It also supports the addition of new modules without requiring the revision of the interfaces of existing modules.

### 2.2 Sentence Planner Architecture

The architecture of the HealthDoc sentence planner is shown in Figure 1. Solid arrows indicate data flow; dashed arrows indicate control flow. The components are:

1. A set of modules: Discourse Structuring, Content Delimitation, Sentence Structuring, Aggregation, Exophoric Lexical Choice, and

2. Knowledge sources: the lexicon (essentially KPML's lexicon extended by colloctional [Wanner and Bateman, 1990] and qualia [Pustejovsky, 1995] information), the semantic and lexicogrammatical resources as discussed in [Wanner, 1994], the Penman Upper Model [Bateman, 1990], the HealthDoc Domain Model, and the Reader Model of the patient.

3. The blackboards: the main blackboard, which contains the latest pre-SPL expression(s) and their derivation history, and the control blackboard, which contains bookkeeping information such as the flags that signal the status (running/idle/etc.) of each module.

4. The Administrator: the top-level process that invokes modules, updates pre-SPL expressions, manages parallel alternative expressions, etc.

5. The Tree Transformer: the engine that matches the left-hand sides of tree transfor-
mation rules to pre-SPL expressions and, when they match, unifies all variables and replaces the matched tree fragments with the right-hand sides of the rules.

6. The Network Traverser: a process that traverses the system network of each module, handles the choice criteria functions (typically, these criteria pertain either to the input pre-SPL or to one of the knowledge resources), and upon reaching tree transformation rules, hands them off to the Tree Transformer.

2.3 The Planning Process

The sentence planning process transforms an input TSL expression(s) into one or more SPL expressions.

**Input and output notation.** TSL is currently under development. When fully developed, its degree of detail will be variable from one-to-one equivalent with SPL, to an abstract form that contains only the deep semantic frame for a predication (thereby being a notation in which, for example, *commit suicide* has *suicide* as head, rather than *commit*). The flexible degree of detail of the TSL will allow either more semantic or more surface-oriented sentence planning.

For illustration, compare the following two TSLs of varying degrees of abstraction for sentences (1) to (3) above:

**A more abstract TSL expression:**

\[
(D1 / \text{disjunction}
\begin{align*}
&:\text{domain} (W / \text{wearout}) \\
&:\text{actor} (I1 / \text{implant}) \\
&:\text{number} \text{ singular} \\
&:\text{tense present} \\
&:\text{range} (D2 / \text{disjunction}) \\
&:\text{domain} (L / \text{loosen}) \\
&:\text{actor} I1 \\
&:\text{tense present} \\
&:\text{range} (F / \text{fail}) \\
&:\text{actor} I1 \\
&:\text{tense present} \\
&:\text{circumstance} (O / \text{occasional}) \\
&:(C1 / \text{condition}) \\
&:\text{domain} (R / \text{remove}) \\
&:\text{actee} I1 \\
&:\text{modality} \text{ must} \\
&:\text{range} D1)
\end{align*}
\]

Note that coreference information is here encoded by using the same variables.

**A more specific TSL expression:**

\[
(D1 / \text{disjunction}
\begin{align*}
&:\text{domain} (W / \text{wearout}) \\
&:\text{actor} (I1 / \text{implant}) \\
&:\text{number} \text{ singular} \\
&:\text{tense present} \\
&:\text{range} (D2 / \text{disjunction}) \\
&:\text{domain} (L / \text{loosen}) \\
&:\text{actor} I1 \\
&:\text{tense present} \\
&:\text{range} (F / \text{fail}) \\
&:\text{actor} I1 \\
&:\text{tense present} \\
&:\text{three-d-location} \\
&:(C1 / \text{condition}) \\
&:\text{domain} (R / \text{remove}) \\
&:\text{actee} I1 \\
&:\text{modality} \text{ must} \\
&:\text{range} D1)
\end{align*}
\]

In the more specific TSL expression, the deep semantic roles have been replaced by surface semantic roles (:actor, :actee), and syntactic information (tense) and textual information (theme) have been added. To see the difference between the TSL and SPL, consider the SPL expression for the first sentence in (0)–(3):

**SPL output expression:**

\[
(D1 / \text{disjunction}
\begin{align*}
&:\text{domain} (W / \text{nondirected-action}) \\
&:\text{lex} \text{ wear-out} \\
&:\text{tense} \text{ present} \\
&:\text{actor} (I1 / \text{object}) \\
&:\text{lex} \text{ implant} \\
&:\text{number} \text{ plural} \\
&:\text{range} (D2 / \text{disjunction}) \\
&:\text{domain} (L / \text{nondirected-act.}) \\
&:\text{lex} \text{ loosen} \\
&:\text{tense} \text{ present} \\
&:\text{actor} I1 \\
&:\text{range} (F / \text{nondirected-act.}) \\
&:\text{lex} \text{ fail} \\
&:\text{tense} \text{ present} \\
&:\text{actor} I1 \\
&:\text{three-d-location} \\
&:(C1 / \text{condition}) \\
&:\text{lex} \text{ instance} \\
&:\text{number} \text{ plural} \\
&:\text{determiner} \text{ some})
\end{align*}
\]

Overall planning process. The planning process starts with the Administrator, which places a pre-SPL fragment onto the blackboard
and activates a module.

Linguistically, it is not possible to presuppose a fixed sequence in which the modules should apply [De Smedt, 1990; Nirenburg et al., 1989]. In some cases, mutual dependencies exist between different linguistic phenomena (i.e., also planning tasks) that cause race conditions or deadlock. We briefly discuss conflict resolution strategies in Section 4. In general, though, we define a (partial) default sequence for the modules: the Discourse Structuring and Sentence Structuring modules run first, and in parallel. They are followed by the Content Delimitation module, and finally by the Exophoric and Endophoric Choice modules, also in parallel. This is in accordance with the increasing delicacy of phenomena the modules deal with. However, we will also experiment with other sequences. A user-specifiable Agenda that determines the ordering of module application has been implemented.

Upon activation, a module removes a pre-SPL from the blackboard, refines and enriches it, and replaces it on the blackboard. The outputs of parallel modules are unified and the unified pre-SPL expression becomes the working copy. The output of non-parallel modules become the working copy immediately. After all modules have run, the constructed sPL on the blackboard is passed to KPML for realization.

In our current implementation, all modules except Discourse Structuring are defined uniformly using system networks. This allows us to adopt an already developed and well-known representation, and the machinery that processes the information encoded in terms of this representation. For example, in [Panaget, 1994; Wanner, 1994], this machinery has been applied to construct an SPL expression from a ‘text plan’. Unlike this work, which builds up SPL expressions anew using the text plan as a source of information to guide processing, our SP transforms the text plan itself into the SPL. We believe that such a transformation is more transparent to the SP builders, enabling them to inspect and manipulate directly the pre-SPL expressions formed during the planning process. The types of planning operations required remain the same in both cases.

To implement transformation rules in the framework of system networks, we define three new realization operators: REWRITE, ADD, and SUPPLANT. Each operator has a different effect on the fragment(s) of pre-SPL that match its left hand side: REWRITE alters its content or structure, ADD adds new information but alters nothing, and SUPPLANT replaces the matched portion with something else (see [Jakeway et al., 1996]). The transformation rules invoke the Tree Transformer when the features they are associated with are chosen. The Tree Transformer then applies the rules to the current pre-SPL expression.

Four general types of transformation are generally required during sentence planning (symbols preceded by ? are wildcards and match any variable or symbol in the pre-SPL):

1. Augment a pre-SPL expression: 
   \[(\text{ADD} ((?X / \text{CAUSE}) \rightarrow (:\text{dmarker causation})))\]
   in which any fragment of the current pre-SPL containing as head the deep semantic type CAUSE is augmented by the addition of the role :dmarker with the filler causation (i.e., a cue word signaling causation in the surface form).

2. Modify a pre-SPL expression: 
   \[(\text{REWRITE} ((?X / \text{RST-RELATION}) \rightarrow (?X / \text{RST-CAUSE})))\]
   in which the head of a pre-SPL fragment is changed from RST-RELATION to RST-CAUSE.

3. Remove a portion of a pre-SPL expression: 
   \[(\text{SUPPLANT} ((?X / \text{CAUSE} \newline \quad :role1 y \newline \quad :function (:role1 agent)) \rightarrow (?X / \text{CAUSE} \newline \quad :actor y)))\]
   in which the intermediate roles :role1 and :function are removed as soon as the process type (and, therefore, also the name of the agent role) are determined, and replaced by appropriate information.

4. Move a portion of a pre-SPL expression: 
   \[(\text{SUPPLANT} ((?X / \text{PROCESS} \newline \quad :situation y) \rightarrow (?X / y)))\]
in which the intermediate role $\textit{situation}$ is removed and its filler moved to occupy the head of the fragment rooted at $?x$. (This occurs when it has been decided that the predicate $y$ — e.g., $\textit{move}$ — is to be expressed as the verb [to] $\textit{move}$, rather than as the support verb construction $\textit{make a move}$; now $\textit{move}$ must be promoted to be the head of $?x$ in the emerging $\textit{SPL}$.) Note that 'remove a fragment' always implies 'move a fragment'.

2.4 Inter-Module Conflict Resolution

If a module is activated but is not able to make all the decisions it needs to, or if it makes decisions that are known to be possibly incompatible with those made by other modules later on, there are in general three options for how to proceed:

1. The module must suspend operation until all information required is available.
2. The module must make decisions somewhat blindly and allow backtracking when a decision turns out later to be incompatible.
3. The module must not make the decision but produce all alternatives in parallel, to be winnowed out by later processing.

We do not discuss the first two options since they are standard AI search techniques. The third option is inspired by the treatment of alternatives in statistics-based NLP and the way alternative options are handled in $\textit{MTM}$ [Mel'čuk, 1981]. In this option, we allow a module to replace an input with multiple alternative outputs instead of only one when it cannot make a choice. All such alternative pre-$\textit{SPL}$s are spawned and propagated onto the blackboard, so that other modules can work on them all, as parallel alternatives. Should one of the alternatives later turn out to be incompatible with some module's decision, that alternative simply 'dies' and is removed from the blackboard. If, on the other hand, all alternatives remain viable to the end, then the $\textit{SP}$ has produced more than one valid locution from the input. This option is only feasible if the networks of the modules are not very detailed, i.e., do not lead to an excessive number of alternatives. Although we will experiment with all three modes, our primary intention is to employ mode 1; currently, for implementational reasons, we use mode 2 in its simplest instantiation: when the changes made by a module turn out to be incompatible with those of other modules, the module starts again.

3 The Modules

This section describes the functionality of each module. As an example, we show the creation of the $\textit{SPL}$ expressions for the sentences (1) to (3). Lack of space prevents us from discussing the criteria and heuristics that are responsible for the individual choices.

3.1 Discourse Structuring Module

The Discourse Structuring module decides upon the way a discourse relation is communicated. So far, three major distinctions are made:

1. Marker/no-marker: For example, the $\textit{CONDITION}$ relation can be marked by $\textit{if}$, $\textit{in}$ case, etc.
2. Explicit/implicit: $\textit{CONDITION}$ can be communicated explicitly by discourse means and/or lexical means (such as the verb $\textit{necessitate}$), or implicitly, obtainable via inference.
3. Nucleus/satellite salience: In the case of $\textit{CONDITION}$, salience can be shifted by change of the order of the condition and effect arguments.

The pre-$\textit{SPL}$ expression created by the Discourse Structuring module reflects the choices made regarding sentences 1 to 3 above in the type and number of roles to introduce, the role filler information, etc. The following fragment shows the result of the discourse structuring module for the sample sentences:

\[
\begin{align*}
&\text{(D1)} \\
&(\text{C1} / \text{condition}) \\
&\quad :\text{domain} (\text{R} / \text{remove}) \\
&\quad \quad :\text{actee} \text{I1} \\
&\quad \quad :\text{modality must} \\
&\quad :\text{range} \text{D1}) \\
&\quad :\text{dmarker} \text{condition} \\
&\quad :\text{range-ordering first})
\end{align*}
\]

The fragment D1 is not changed. For fragment C1, the use of a discourse marker has been determined. Also, due to the salience of the condition part of the utterance, the ':range' role will be expressed first.

3.2 Sentence Structuring Module

The Sentence Structuring module determines the structure of the sentences to be encoded in
the SPL. This includes:
1. Sentence boundaries: If two separate sentences are to be produced, the SPL is split into one per sentence and built up sequentially.

2. Global sentence structure: A sentence can be a hypotactic clause complex, a paratactic clause complex, or a simple clause. To determine this, the Sentence Structuring module evaluates whether the predications in the pre-SPL are to be communicated as a sequence or as a composite, complex event. A sequence of events can further be emphasized by a marker.

In our example, the SPL under construction undergoes the following changes:

\[
((D1 / disjunction \\
  :domain W \\
  :range (D2 / disjunction \\
    :domain L \\
    :range F \\
    :dmarker disjunction) \\
  :dmarker - \\
  :nonorienting I2 \\
  :theme I2) \\
C1)
\]

It has been determined that the first SPL will contain a paratactic clause complex and that there will be a disjunction marker between the L and F fragments. Since a CONDITION that is represented by the roles :domain and :range is expressed in KPML as a hypotactic clause complex, fragment C1 remains unchanged (note that the aggregation module still has not run to make the changes for (3)).

3.3 Content Delimitation Module
The Content Delimitation module determines the material to be included into each separate SPL expression. At the present stage, this includes the following:
1. Constituents of a predication: Constituents that are to be encoded in the pre-SPL. Depending on the contextual and linguistic constraints, roles that are listed in the input might be suppressed and additional ones might be introduced.
2. Causal, temporal, aspectual nuances: Nuances of the predication that are to be encoded in the pre-SPL.

The Content Delimitation module primarily introduces realization statements into the pre-SPL expression that constrain the exophoric choice module.

In our example, which starts from a relatively specific TSL, the content delimitation module does not make visible changes: all roles present in the pre-SPL are determined to be realized. Starting from the abstract TSL, intermediate roles :situation would have been introduced in the fragments labeled by the variables W, L, F, and R. This syntactically neutral role :situation enables the Exophoric Choice module to generate different internal clause structures.

3.4 Aggregation Module
The Aggregation module eliminates redundancy in the pre-SPL by grouping entities that are arguments of the same relation, process, etc., together. The actions of the Aggregation module affect, as a rule, the resulting syntactic structure. In our example, redundancy is apparent in pre-SPL fragments W, L, and F, since their only internal difference is their type, as well as the repetition of the whole D1 in fragment C1.

The actions of the Aggregation module result in the following changes within pre-SPL C1 for sentence (3):

\[
(C / conjunction \\
  :domain (R / remove \\
    :actee I1 \\
    :lex zeroellipsis \\
    :modality must) \\
  :range D1 \\
  :range-ordering first)
\]

3.5 Exophoric Lexical Choice Module
The Exophoric Lexical Choice module chooses lexical units for those entities specified in the pre-SPL that are new in the discourse. More precisely, it makes the pre-SPL more concrete along three lines:
1. Lexicalization of discourse structure relations: Discourse relations (and their cue words) may be realizable by lexical means. In our example, the CONDITION marker in (1), (2) is lexicalized as if; the DISJUNCTION marker as or, and the CONJUNCTION marker as and.
2. Internal clause structuring: The internal clause structure is predetermined by, among other means, the valency schema of the lexical unit that is chosen to serve as a head of a clause or phrase. With the choice of a head lexical
unit, the salience of the arguments is also pre-
determined (see, e.g., [Wanner and Bateman,
1990]). One of the choices the exophoric lexi-
cal choice module makes while generating (2),
is the replacement of the fragment D1 in the
CONDITION part by *If replacement is needed.*
This choice can be made because the KB con-
tains the process of replacement as a possible
consequence of an implant being worn out, loos-
ened, or having failed. It is not motivated by the
presence of the coreference link in the TSL. The
pre-SPL reflects this choice as follows:

```
(D1
  (C1 / condition
    :domain (R / remove
      :actee I1
      :modality must)
    :range (N / need
      :actee (RE / replacement))
    :dmarker condition
    :range-ordering first))
```

3. Lexicalization of the entities: this is
traditionally considered to be the task of the
lexical choice process. We do not discuss this
issue here.

3.6 Endophoric Lexical Choice Module
The Endophoric Lexical choice module chooses
lexical units for entities that have already been
introduced in the discourse either verbatim or
by related entities. If an entity has been intro-
duced verbatim, its next mention can be real-
ized as a personal pronoun, generalized name,
definite name, deictic pronoun, or ellipsis. If a
related entity has been introduced, the new lexi-
cal unit depends on the relation between the two
entities; compare [Tutin and Kittredge, 1992].

In our example, if the Exophoric module
runs first, the Endophoric module ends up only
pronominalizing *implant* in the last clause. If
instead the Endophoric module runs first, the
SPL produced is (1) rather than (2), i.e., the
Endophoric Choice module chooses the phrase
*this happens* to refer to *an implant wears out,
loosens, or fails.* If we assume this variant, the
pre-SPL expression for the second sentence is
changed to:

```
(C1 / condition
  :domain (R / remove
    :actee I1
    :modality must)
  :range (H / happen
    :actor (I1 / implant
      :lex this))
  :dmarker condition
  :range-ordering first)
```

4 Related Research
Related work falls into two areas. The first is
sentence planning as a task, including the orga-
nization of the planning process. The second
covers specific subtasks of sentence planning.
Since we have already provided extensive refer-
ences to work in the second area, and our focus
in this paper is not on the detailed presentation
of these subtasks, we refrain from discussing it
further.

In the first area, our SP appears, at first
glance, to closely resemble DIOGENES [Niren-
burg et al., 1989]: both systems contain a black-
board with different sentence planning tasks
performed by separate modules. However, sig-
nificant differences exist with respect to pro-
cessing strategies, including blackboard man-
agement and conflict resolution; the assignment
of different subtasks to modules; the organiza-
tion of the modules; and the organization of
knowledge resources. This issue is discussed in
[Jakeway et al., 1996].

In other related work [Appelt, 1985; Meeter,
1991; Horacek, 1992], several sentence plan-
ning tasks are treated within the process of
text planning. [Rambow and Korelsky, 1992;
Panaget, 1994] have a separate sentence plan-
ning component, but they do not separate the
specific subtasks of sentence planning into dis-
tinct submodules. Necessarily, some subtasks,
such as content delimitation, exophoric, and en-
dophoric choice, then play a less prominent role.

5 Conclusion
Individual sentence planning tasks have been
the focus of much previous research. A few
sentence planners have combined some of these
tasks in a single engine. With the HealthDoc
sentence planner, we are attempting to build an
architecture that supports both the addition of
new sentence planning tasks, in the form of new
modules, as well as continued growth in sophis-
tication and coverage of individual task perfor-
ance. This is an ambitious goal. We believe
that a blackboard architecture with separate modules, a situation discrimination mechanism such as feature networks, and a continuously transformable internal representation, from TSL input to SPL output using tree transformation operators, to be a promising avenue of research, given the complexity of the problems facing text generators.

Acknowledgments

We would like to thank Bruce Jakeway for implementations as well as the other members of the Sentence Planning Group, Chrysanne DiMarco, Phil Edmonds, and Daniel Marcu, for many fruitful discussions. Special thanks to John Wilkinson, who was one of the “Key Sentence Planners” during the first phase of our work.
