CONSTRUCTING ELEMENTS AND THE GROWTH OF QUASI-CONVEX SUBGROUPS

by Xabier LEGASPI

15th June 2022

Abstract. — Given a group $G$ acting on a geodesic metric space, we consider a preferred collection of paths of the space – a path system – and study the spectrum of relative exponential growth rates and quotient exponential growth rates of the infinite index subgroups of $G$ which are quasi-convex with respect to this path system. If $G$ contains a constricting element with respect to the same path system, we are able to determine when the first kind of growth rates are strictly smaller than the growth rate of $G$, and when the second kind of growth rates coincide with the growth rate of $G$. Examples of applications include relatively hyperbolic groups, $CAT(0)$ groups and hierarchically hyperbolic groups containing a Morse element.

1. Introduction

Recall that an isometric action of a group $G$ on a metric space $(X, d)$ is proper if any ball $B_G(x, r)$ of $G$ based at $x \in X$ of radius $r \geq 0$ is finite, where

$$B_G(x, r) = \{ g \in G : d(x, gx) \leq r \}.$$ 

Let $o \in X$. Let $H$ be a subgroup of $G$. The relative exponential growth rate of $H$ is

$$\omega_H = \limsup_{r \to \infty} \frac{1}{r} \log |B_G(o, r) \cap H|.$$ 

The quotient exponential growth rates of $H$ are

$$\omega_{G/H} = \limsup_{r \to \infty} \frac{1}{r} \log |\mathcal{L}(B_G(o, r))|, \quad \omega_{H \setminus G} = \limsup_{r \to \infty} \frac{1}{r} \log |\mathcal{R}(B_G(o, r))|,$$

where $\mathcal{L} : G \to G/H$ and $\mathcal{R} : G \to H \setminus G$ are the natural maps respectively on the set of left cosets $G/H$ and on the set of right cosets $H \setminus G$. Note that the numbers $\omega_H$, $\omega_{G/H}$ and $\omega_{H \setminus G}$ do not depend on the choice of the point $o \in X$. The original motivation for our work was the following problem:

PROBLEM 1.1. — Determine the groups $G$ acting properly on metric spaces $X$ and subgroups $H$ of $G$ which are solution to the system of equations

$$\begin{cases} 
\omega_H < \omega_G, \\
\omega_{G/H} = \omega_{H \setminus G} = \omega_G.
\end{cases}$$

We see from the definition that $0 \leq \max \{ \omega_H, \omega_{G/H}, \omega_{H \setminus G} \} \leq \omega_G$. In the extreme case in which $H$ is a finite index subgroup of $G$, one can easily prove that

$$\begin{cases} 
\omega_H = \omega_G, \\
\omega_{G/H} = \omega_{H \setminus G} = 0 \leq \omega_G.
\end{cases}$$

In general, it is very hard to obtain any estimation of the relative and quotient exponential growth rates of the infinite index subgroups of $G$. However, we know [DFW19], [Ant21], [GR20] that if $G$ is a non-virtually cyclic group acting geometrically on a hyperbolic space $X$ and $H$ is
an infinite index quasi-convex subgroup of $G$, then
\[
\begin{cases}
\omega_H < \omega_G, \\
\omega_{G/H} = \omega_{H \cap G} = \omega_G.
\end{cases}
\]
In particular, the authors of [DFW19] and [Ant21] were highly influenced by J. Cannon’s arguments based on automatic structures and regular languages. This fact also influenced others that partially extended the hyperbolic result [CRSZ20].

In this article we go beyond the hyperbolic case and we obtain elementary proofs of two main results (Theorem 1.8 and Theorem 1.11) that do not require the theory of regular languages and automatas. We will be interested in groups acting properly on geodesic metric spaces conditioned by a very general notion of «non-positive curvature» introduced by A. Sisto in [Sis18] — containing a constricting element with respect to a path system — while the infinite index subgroups object of our study will satisfy a very general notion of «convex cocompactness» — quasi-convexity with respect to a path system.

First of all, we will mention two applications. Later we will give an informal explanation of our general setting as the result of a natural generalisation of these applications. We expect that this will be enough to understand our main theorems stated right after that. We will give another application at the end.

(A) Groups acting properly with a strongly contracting element. Members of this class contain elements that “behave like” a loxodromic isometry in a hyperbolic space – in a strong way. Let $\delta \geq 0$. A subset $A$ of $X$ is $\delta$-strongly contracting if the diameter of the nearest-point projection on $A$ of any ball of $X$ not intersecting $A$ is less than $\delta$. An element $g$ of $G$ is $\delta$-strongly contracting if it has infinite order and there exists $o \in X$ such that the orbit $\langle g \rangle o$ is $\delta$-strongly contracting.

In his seminal paper M. Gromov introduced the concept of $\delta$-hyperbolic space [Gro87]. He observed that most of the large scale features of negative curvature can be described in terms of thin triangles. Nowadays, there are plenty of reformulations of the $\delta$-hyperbolicity. In particular, H. Masur and Y. Minsky gave one by describing geodesics in terms of strong contraction:

**Example 1.2.** — A geodesic metric space $X$ is hyperbolic if and only if there exists $\delta \geq 0$ such that any geodesic segment of $X$ is $\delta$-strongly contracting [MM99, Theorem 2.3].

The following are some subclasses of groups acting properly with a strongly contracting element:

(I) $H =$ “$G$ is a group acting properly with a loxodromic element on a hyperbolic space $X$.”

In $H$, an element is loxodromic if and only if it is strongly contracting. See [CDP90].

(II) $RH =$ “$G$ is a relatively hyperbolic group acting with a hyperbolic element on a locally
finite Cayley graph $X$ of $G.$” In RH, hyperbolic elements are strongly contracting. See [Osi06, Corollary 1.7] and [Sis13, Theorem 2.14].

(III) CAT$_0 = "G is a group acting properly with a rank-one element on a proper CAT(0) space $X."$ In CAT$_0$, rank-one elements are strongly contracting. See [BF09, Theorem 5.4], [Cas20] and [Gen21, Proposition 2.8].

(IV) MCG$_T = "G is the mapping class group of an orientable surface of genus $g$ and $p$ marked points of complexity $3g + p - 4 > 0$ acting on its Teichmüller space endowed with the Teichmüller metric." In MCG$_T$, pseudo-Anosov elements are strongly contracting. See [Min96] and [MM99, Proposition 4.6].

(V) GSC = "G is an infinite graphical small cancellation group associated to a $Gr^t(1/6)$-labeled graph with finite components labeled by a finite set $S$, acting on the Cayley graph $X$ of $G$ with respect to $S."$ In GSC, loxodromic WPD elements for the action of $G$ on the hyperbolic coned-off Cayley graph constructed by D. Gruber and A. Sisto in [GS18] are strongly contracting. See [ACGH19, Theorem 5.1].

(VI) Gar = "G is the quotient of a $\Delta$-pure Garside group of finite type by its center, acting with a Morse element on the Cayley graph $X$ of $G$ with respect to the Garside generating set." In Gar, Morse elements are strongly contracting. See [CW21, Theorem 5.5].

An appropriate notion of convex cocompactness in this setting is just the usual quasi-convexity. A subgroup $H$ of $G$ is quasi-convex if there exist $o \in X$ and $\eta \geq 0$ such that any geodesic of $X$ with endpoints in $Ho$ is contained in the $\eta$-neighbourhood of $Ho$.

The theorem below generalises [Yan19, Theorem 4.8] and [DFW19, Theorems 1.1 and 1.3]:

**Theorem 1.3.** — If $G$ is a non-virtually cyclic group acting properly with a strongly contracting element on a geodesic metric space $X$, and $H$ is an infinite index quasi-convex subgroup of $G$, then

$$\begin{cases} \omega_H < \omega_G, \\
\omega_{G/H} = \omega_{H\backslash G} = \omega_G. \end{cases}$$

**B) Hierarchically hyperbolic groups.** Let $MCG(\Sigma_{g,p})$ be the mapping class group of an orientable surface $\Sigma_{g,p}$ of genus $g$ and $p$ marked points of complexity $3g + p - 4 > 0$. We would like to apply Theorem 1.3 to $MCG(\Sigma_{g,p})$ with respect to the word metric. However, we do not know whether $MCG(\Sigma_{g,p})$ acts with a strongly contracting element on any of its locally finite Cayley graphs or not. Maybe the candidates that come to mind are the pseudo-Anosov elements, and evidence suggest that not all of them are strongly contracting: K. Rafi and Y. Verberne have constructed a generating set $S$ of $MCG(\Sigma_{0,5})$ and a pseudo-Anosov element which is not strongly contracting for the action of $MCG(\Sigma_{0,5})$ on the Cayley graph.
of $MCG(\Sigma_{0,5})$ with respect to $S$ [RV21, Theorem 1.3]. We were able to avoid this setback by looking into the class of hierarchically hyperbolic groups, introduced in [BHS17] and [BHS19] as a generalisation of the Masur and Minsky hierarchy machinery of mapping class groups. Below we provide some subclasses of hierarchically hyperbolic groups. The reader should note that the metric space where they act with a hierarchically hyperbolic structure is any of their locally finite Cayley graphs:

(I) Mapping class groups of finite type surfaces [BHS19].

(II) Right-angled Artin groups [BHS17].

(III) Right-angled Coxeter groups [BHS17].

(IV) Fundamental groups of 3-manifolds without Nil or Sol components [BHS19].

Now consider the following notion of convex cocompactness. A subgroup $H$ of $G$ is Morse if there exists $o \in \mathcal{X}$ such that for every $\kappa \geq 1$, $\lambda \geq 0$, there exists $\sigma \geq 0$ such that any $(\kappa, \lambda)$-quasi-geodesic of $\mathcal{X}$ with endpoints in $Ho$ is contained in the $\sigma$-neighbourhood of $Ho$. An element $g$ of $G$ is Morse if it has infinite order and $\langle g \rangle$ is Morse.

We have obtained the next result, partially generalising [CRSZ20, Theorem A]:

**Theorem 1.4.** — If $G$ is a non-virtually cyclic hierarchically hyperbolic group acting on a locally finite Cayley graph $X$ of $G$ with a Morse element, and $H$ is an infinite index Morse subgroup of $G$, then

\[
\begin{cases}
\omega_H < \omega_G, \\
\omega_{G/H} = \omega_{H \backslash G} = \omega_G.
\end{cases}
\]

We know that pseudo-Anosov elements of mapping class groups are Morse with respect to any word metric [Beh06], which allows us to obtain a more concrete statement:

**Corollary 1.5.** — If $G$ is the mapping class group of a surface of genus $g$ and $p$ marked points such that $3g + p - 4 > 0$ acting on a locally finite Cayley graph $X$ of $G$, and $H$ is an infinite index Morse subgroup of $G$, then

\[
\begin{cases}
\omega_H < \omega_G, \\
\omega_{G/H} = \omega_{H \backslash G} = \omega_G.
\end{cases}
\]

Now that we gave the big picture, we will give a technical definition that encapsulates the classes discussed so far. In order to do so, we make two observations. On the one hand, the strong contraction property can be reformulated in the following way. An element $g$ of $G$ is strongly contracting if and only if it has infinite order and there exists $o \in \mathcal{X}$ such that any geodesic segment of $\mathcal{X}$ joining any pair of points $x, y \in \mathcal{X}$ whose projections $\pi_g(x)$ and $\pi_g(y)$ via
a nearest-point projection $\pi_g : X \to \langle g \rangle o$ are far away passes near these two projections [ACT15, Proposition 2.9]. On the other hand, mapping class groups – or more generally, hierarchically hyperbolic groups – come with hierarchy paths, a family of special quasi-geodesics encoding substantial information about the geometry of the space and easier to work with than the set of all (quasi-)geodesics. For these reasons, in order to define very general notions of non-positive curvature and convex cocompactness, we will be considering path systems, introduced by A. Sisto in [Sis18]:

**Definition 1.6 (Path system group).** — Let $\mu \geq 1$, $\nu \geq 0$. A $(\mu, \nu)$-path system group $(G, X, \Gamma)$ is a group $G$ acting properly on a geodesic metric space $X$ together with a $G$-invariant collection $\Gamma$ of paths of $X$ satisfying:

(PS1) $\Gamma$ is closed under taking subpaths.

(PS2) For every $x, y \in X$, there exists $\gamma \in \Gamma$ joining $x$ to $y$.

(PS3) Every element of $\Gamma$ is a $(\mu, \nu)$-quasi-geodesic.

We refer to $\Gamma$ as $(\mu, \nu)$-path system.

We fix $\mu \geq 1$, $\nu \geq 0$ and a $(\mu, \nu)$-path system group $(G, X, \Gamma)$ for the following definitions. Let $\delta \geq 0$. We say that an element $g$ of $G$ is $\delta$-constricting if it has infinite order and there exist $o \in X$ and a coarse nearest-point projection $\pi_g : X \to \langle g \rangle o$ with the property that any $\gamma \in \Gamma$ joining any two points $x, y \in X$ such that $d(\pi_g(x), \pi_g(y)) > \delta$ passes through the $\delta$-neighbourhoods of the points $\pi_g(x)$ and $\pi_g(y)$. See Definition 2.8. In particular we have the following examples:

**Example 1.7.** — (I) An infinite order element of $G$ is strongly contracting if and only if it is constricting with respect to the set of all the geodesic segments of $X$ [ACT15, Proposition 2.9].

(II) Assume that $G$ is also hierarchically hyperbolic. An infinite order element $g$ of $G$ is Morse if and only if for every $\kappa \geq 1$, there exists $\delta \geq 0$ such that $g$ is $\delta$-constricting with respect to the set of all the $\kappa$-hierarchy paths. See [RST21, Theorem E] and [BHS20, Lemma 1.27].

Let $\eta \geq 0$. A subgroup $H$ of $G$ is $\eta$-quasi-convex if there exists $o \in X$ such that any $\gamma \in \Gamma$ with endpoints in $Ho$ is contained in the $\eta$-neighbourhood of $Ho$. See Definition 2.7.

Finally, we state the main results of this article. Theorem 1.3 and Theorem 1.4 are special cases. Our first result generalises [Yan19, Theorem 4.8] and [DFW19, Theorems 1.1 and 1.3]. The Poincaré series $P_H(s)$ based at $o \in X$ of a subgroup $H$ of $G$ is defined as

$$\forall s \geq 0, \quad P_H(s) = \sum_{h \in H} e^{-sd(o, ho)}$$
and modifies its behaviour at the relative exponential growth rate $\omega_H$: the series diverges if $s < \omega_H$ and converges if $s > \omega_H$. In $s = \omega_G$ the series can converge or diverge depending on the nature of $H$. This behaviour is independent of the point $o \in X$. We say that the subgroup $H$ is divergent if $\mathcal{P}_H(s)$ diverges at $s = \omega_H$.

**Theorem 1.8.** — Let $(G, X, \Gamma)$ be a path system group. Assume that $G$ contains a constricting element. Let $H$ be an infinite index subgroup of $G$. Assume that the following conditions are true:

(I) $\omega_H < \infty$.

(II) $H$ is divergent.

(III) $H$ is quasi-convex.

Then $\omega_H < \omega_G$.

We make the following remark. Under the hypothesis of Theorem 1.8, one may ask if there is a growth gap $\sup_H \omega_H < \omega_G$, where the supremum is taken among the infinite index subgroups $H$ of $G$ satisfying (I), (II) and (III). In our context, the answer is yes: there is a growth gap when $G$ is a hyperbolic group with Kazhdan’s property (T) [CDST18, Theorem 1.2]. However, one can show that there is no growth gap among free groups [DFW19, Theorem 9.4] or fundamental groups of compact special cube complexes [LW20, Theorem 1.5]. The answer to our context could be different if one studied semigroups instead of subgroups [Yan19, Theorem A].

In [Gro87, 5.3.C], M. Gromov stated that in a torsion-free hyperbolic group $G$, any infinite index quasi-convex subgroup $H$ is a free factor of a larger quasi-convex subgroup. Gromov’s ideas were later developed by G. N. Arzhantseva in [Arz01, Theorem 1]. More recently, J. Russell, D. Spriano and H. C. Tran generalised her result to the context of groups with the «Morse local-to-global property» [RST19, Corollary 3.5]. In our context, we have obtained the following, in which there is no torsion-free assumption. We will see that Theorem 1.8 is, in part, a consequence of this result:

**Theorem 1.9.** — Let $(G, X, \Gamma)$ be a path system group. Assume that $G$ contains a constricting element $g_0$. Let $H$ be an infinite index quasi-convex subgroup of $G$. There exist an element $g \in G$ conjugate to a large power of $g_0$ and a finite extension $E$ of $\langle g \rangle$ such that the intersection $H \cap E$ is finite and the natural morphism $H \ast_{H \cap E} \langle g, H \cap E \rangle \to G$ is injective.

According to our Proposition 2.5 (6), the subgroup generated by a constricting element is always Morse, and in particular quasi-convex. Hence we obtain a weak version of the Tits alternative:
COROLLARY 1.10. — Let \((G, X, \Gamma)\) be a path system group. Assume that \(G\) contains a constricting element. Then, either \(G\) is virtually cyclic or contains a free subgroup of rank two.

To the best of our knowledge, the previous corollary has not been recorded for the class of groups acting properly with a strongly contracting element. Besides, the Tits alternative is known for hierarchically hyperbolic groups [DHS17, Theorem 9.15].

In our second result we generalise [Ant21, Theorem 3] and [GR20, Theorem 2]:

**THEOREM 1.11.** — Let \((G, X, \Gamma)\) be a path system group. Assume that \(G\) contains a constricting element. Let \(H\) be an infinite index quasi-convex subgroup of \(G\). Then

\[
\omega_{G/H} = \omega_{H\setminus G} = \omega_{G}.
\]

Note that the study of [GR20, Theorem 2] concerns double cosets in the hyperbolic group case. We remark that in [dlH00, VII D 39], P. de la Harpe says about the growth of double cosets: «this theme has not received yet too much attention, but probably should». In our context, for sake of simplicity, we decided to study single cosets instead, but one could possibly extend our result. Further, we remark that our result is connected to the study of I. Kapovich on the hyperbolicity and amenability of the Schreier graphs of infinite index quasi-convex subgroups of hyperbolic groups [Kap02a], [Kap02b].

Now we are going to record a joint corollary to Theorem 1.8 and Theorem 1.11. In general, it is not easy to decide whether or not a group is convergent or divergent. However, the following is well-known:

**PROPOSITION 1.12 ([DPPS11, Proposition 4.1 (1)]).** — Let \(G\) be a group acting properly on a geodesic metric space \(X\). Let \(o \in X\). Let \(H \leq G\) be a quasi-convex subgroup (in the classical sense). Then

\[
\omega_{H} = \inf_{r \geq 1} \frac{1}{r} \log |B_{G}(o,r) \cap H| = \lim_{r \to \infty} \frac{1}{r} \log |B_{G}(o,r) \cap H|.
\]

In particular \(\omega_{H} < \infty\). Besides, if \(H\) is also infinite, then it is divergent.

In combination with Corollary 1.10, we obtain:

**COROLLARY 1.13.** — Let \((G, X, \Gamma)\) be a path system group. Assume that \(G\) is non-virtually cyclic and contains a constricting element.

(I) If \(\Gamma\) is the set of all the geodesic segments of \(X\), then for every infinite index quasi-convex subgroup \(H\) of \(G\), we have

\[
\begin{cases}
\omega_{H} < \omega_{G}, \\
\omega_{G/H} = \omega_{H\setminus G} = \omega_{G}.
\end{cases}
\]
(II) For every infinite index Morse subgroup $H$ of $G$, we have

$$\begin{cases} 
\omega_H < \omega_G, \\
\omega_{G/H} = \omega_{H\backslash G} = \omega_G.
\end{cases}$$

Remark 1.14. — One can prove that the class of groups acting properly with a constricting element with respect to a path system is invariant under equivariant quasi-isometries. However, the class of groups acting properly with a strongly contracting element is not invariant under equivariant quasi-isometries [ACGH19, Theorem 4.19]. In particular, Corollary 1.13 applies for instance to the action on a locally finite Cayley graph of any group acting geometrically on a $CAT(0)$ space with a rank-one element.

Remark 1.15. — The proofs of Theorem 1.3 and Theorem 1.4 now follow from our main results (Theorem 1.8 and Theorem 1.11) in view of Example 1.7.

Finally, we deduce the another application from Theorem 1.8 and Theorem 1.11:

(C) Hierarchical quasi-convexity. In hierarchically hyperbolic groups there is a notion of convex cocompactness more natural than Morseness. Let $G$ be a hierarchically hyperbolic group. A subgroup $H$ of $G$ is hierarchically quasi-convex if and only if for every $\kappa \geq 1$, there exists $\eta \geq 0$ such that $H$ is $\eta$-quasi-convex with respect to the set of all the $\kappa$-hierarchy paths of $G$. See [RST21, Proposition 5.7].

Theorem 1.16. — If $G$ is hierarchically hyperbolic group acting on a locally finite Cayley graph $X$ of $G$ with a Morse element, and $H$ is an infinite index subgroup of $G$ satisfying

(I) $H$ is divergent,

(II) $H$ is hierarchically quasi-convex,

then $\omega_H < \omega_G$.

Theorem 1.17. — If $G$ is a hierarchically hyperbolic group acting on a locally finite Cayley graph $X$ of $G$ with a Morse element, and $H$ is an infinite index hierarchically quasi-convex subgroup of $G$, then $\omega_{G/H} = \omega_{H\backslash G} = \omega_G$.

Outline of the paper. In Section 2 we will introduce the definitions of path system group, quasi-convex subgroup and constricting element. We also state some standard properties. In Section 3 we will explain the two criteria that we will use to estimate the relative and quotient exponential growth rates. The rest of the paper is devoted to the development of our geometric framework so that we can apply these criteria. In Section 4 we will prove a version of the «Bounded Geodesic Image Property» of hyperbolic spaces, but for quasi-convex subsets instead of geodesics. In Section 5 we will introduce the notion of buffering sequence and we will give a version of «Behrstock inequality». In Section 6, given an infinite index quasi-convex
subgroup and a quasi-convex element, we will produce another quasi-convex element whose orbit is «transversal» to the given subgroup. The proofs of both of our main results (Theorem 1.8 and Theorem 1.11) share this argument. In Section 7 we will study the elementary closures of constricting elements and also some geometric separation properties. Finally, in Section 8 we will prove our main results (including Theorem 1.9) by constructing an appropriate buffering sequence in each situation.

Acknowledgements. The author is deeply indebted to his supervisors Yago Antolín and Rémi Coulon. He would like to thank them for their many comments, suggestions, words of support and for reading earlier versions of this draft that helped to improve it from scratch. He would also like to acknowledge Markus Steenbock for the many virtual and non-virtual discussions at the very beginning. The author is grateful to the Centre Henri Lebesgue ANR-11-LABX-0020-01 for creating an attractive mathematical environment. He acknowledges support through the grant Outgoing Mobility 2021 of Rennes Métropole.

2. Path system geometry

This section is devoted to present the notations and vocabulary of the main geometric objects of this article. We formalise our notions of «convex-cocompactness» and «non-positive curvature».

2.1. Metric spaces. — Let $X$ be a metric space. Given two points $x, x' \in X$, we write $d(x, x')$ for the distance between them. The ball of $X$ of center $x \in X$ and radius $r \geq 0$ is defined as

$$B_X(x, r) = \{y \in X : d(x, y) \leq r\}.$$ 

The distance between a point $x \in X$ and a subset $Y \subseteq X$ is defined as

$$d(x, Y) = \inf \{d(x, y) : y \in Y\}.$$

Let $\eta \geq 0$. The $\eta$-neighbourhood of a subset $Y \subseteq X$ is defined as

$$Y^{+\eta} = \{x \in X : d(x, Y) \leq \eta\}.$$

The Hausdorff distance between subsets $A, B \subseteq X$ is defined as

$$d_{Haus}(A, B) = \inf \{\varepsilon \geq 0 : A \subseteq B^{+\varepsilon} \text{ and } B \subseteq A^{+\varepsilon}\}.$$ 

2.2. Path system spaces. — Let $X$ be a metric space. A path is a continuous map $\alpha : [a, b] \to X$. We will frequently identify a path and its image. A subpath of $\alpha$ is a restriction of $\alpha$ to a subinterval of $[a, b]$. The path $\alpha$ joins the point $x \in X$ to the point $y \in X$ if $\alpha(a) = x$ and $\alpha(b) = y$.
and \( \alpha(b) = y \). Note that for every \( x, y \in \alpha \) there may be more than one subpath of \( \alpha \) joining \( x \) to \( y \), unless the points are given by the parametrisation of \( \alpha \). The length of a path \( \alpha \) is denoted by \( \ell(\alpha) \). Unless otherwise stated a path is a rectifiable path parametrised by arc length. Let \( \kappa \geq 1 \), \( \lambda \geq 0 \). A path \( \alpha : [a, b] \to X \) is a \((\kappa, \lambda)\)-quasi-geodesic if for every \( t, t' \in [a, b] \),

\[
d(\alpha(t), \alpha(t')) \leq |t - t'| \leq \kappa d(\alpha(t), \alpha(t')) + \lambda.
\]

Note that that \( \ell(\alpha_{[t,t']}) = |t - t'| \). A geodesic is a \((1, 0)\)-quasi-geodesic. The metric space \( X \) is geodesic if for every \( x, y \in X \) there exists a geodesic of \( X \) joining \( x \) to \( y \).

**Definition 2.1 (Path system space).** — Let \( \mu \geq 1 \), \( \nu \geq 0 \). A \((\mu, \nu)\)-path system space \((X, \Gamma)\) is a geodesic metric space \( X \) together with a collection \( \Gamma \) of paths of \( X \) satisfying:

- (PS1) \( \Gamma \) is closed under taking subpaths.
- (PS2) For every \( x, y \in X \), there exists \( \gamma \in \Gamma \) joining \( x \) to \( y \).
- (PS3) Every element of \( \Gamma \) is a \((\mu, \nu)\)-quasi-geodesic.

We refer to \( \Gamma \) as \((\mu, \nu)\)-path system.

We fix \( \mu \geq 1 \), \( \nu \geq 0 \) and a \((\mu, \nu)\)-path system space \((X, \Gamma)\).

**Definition 2.2 (Quasi-convex subset).** — Let \( \eta \geq 0 \). A subset \( Y \subseteq X \) is \( \eta \)-quasi-convex if every \( \gamma \in \Gamma \) with endpoints in \( Y \) is contained in the \( \eta \)-neighbourhood of \( Y \).

**Definition 2.3 (Constricting subset).** — Let \( \delta \geq 0 \). A subset \( A \subseteq X \) is \( \delta \)-constricting if there exists a map \( \pi_A : X \to A \) satisfying:

- (CS1) **Coarse retraction.**
  
  For every \( x \in A \), we have \( d(x, \pi_A(x)) \leq \delta \).

- (CS2) **Constriction.**

  For every \( x, y \in X \) and for every \( \gamma \in \Gamma \) joining \( x \) to \( y \), if \( d(\pi_A(x), \pi_A(y)) > \delta \), then \( \gamma \cap B_X(\pi_A(x), \delta) \neq \emptyset \) and \( \gamma \cap B_X(\pi_A(y), \delta) \neq \emptyset \).

We refer to \( \pi_A : X \to A \) as \( \delta \)-constricting map.

**Notation 2.4.** — Let \( \pi_A : X \to A \) be a map between \( X \) and a subset \( A \subseteq X \). For every \( x, y \in X \), we denote \( d_A(x, y) = d(\pi_A(x), \pi_A(y)) \). For every subset \( Y \subseteq X \), we denote \( \text{diam}_A(Y) = \text{diam}(\pi_A(Y)) \). For every \( x \in X \) and for every pair of subsets \( Y, Z \subseteq X \), we denote \( d_A(x, Y) = d(\pi_A(x), \pi_A(Y)) \) and \( d_A(Y, Z) = d(\pi_A(Y), \pi_A(Z)) \). Note that \( d_A \) may not be a distance over the collection of subsets of \( A \): it may not satisfy the triangle inequality. We will keep this notation for the rest of the paper.
The following are some standard properties:

**Proposition 2.5.** — For every $\delta \geq 0$, there exist a constant $\theta \geq 0$ and a pair of maps, $\sigma: \mathbb{R}_{\geq 1} \times \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ and $\zeta: \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$, such that any $\delta$-constricting map $\pi_A: X \to A$ satisfies the following properties:

1. **Coarse nearest-point projection.**
   
   For every $x \in X$, we have $d(x, \pi_A(x)) \leq \mu d(x, A) + \theta$.

2. **Coarse equivariance.**

   Let $H$ be a group acting by isometries on $X$ such that $A$ and $\Gamma$ are $H$-invariant. Then for every $h \in H$ and for every $x \in X$, we have $d(\pi_A(hx), h\pi_A(x)) \leq \theta$.

3. **Coarse Lipschitz map.**

   For every $x, y \in X$, we have $d_A(x, y) \leq \mu d(x, y) + \theta$.

4. **Intersection–Image.**

   For every $\gamma \in \Gamma$, we have $|\text{diam}(A^{+\delta} \cap \gamma) - \text{diam}_A(\gamma)| \leq \theta$.

5. **Behrstock inequality.**

   Let $\pi_B: X \to B$ be a $\delta$-constricting map. Then for every $x \in X$, we have $\min \{d_A(x, B), d_B(x, A)\} \leq \theta$.

6. **Morseness.**

   Let $\kappa \geq 1$, $\lambda \geq 0$. Let $\alpha$ be a $(\kappa, \lambda)$-quasi-geodesic of $X$ with endpoints in $A$. Then $\alpha \subseteq A^{+\sigma(\kappa, \lambda)}$. 

---

*Figure 1: The constriction property.*
(7) **Coarse invariance.**

Let $\varepsilon \geq 0$. Let $B \subseteq X$ be a subset such that $d_{\text{Haus}}(A, B) \leq \varepsilon$. Then $B$ is $\zeta(\varepsilon)$-constricting.

**Proof.** — We give some references. For (1), (3) and (4), see [Sis18, Lemma 2.4]. For (5), see [Sis18, Lemma 2.5]. For (6), see [Sis18, Lemma 2.8 (1)]. We leave the proof of the properties (2) and (7) as an exercise. \hfill \Box

### 2.3. Path system groups.

Let $G$ be a group acting by isometries on a metric space $X$. The **ball of $G$ based at $x \in X$ of radius $r \geq 0$** is defined as

$$B_G(x, r) = \{ g \in G : d(x, gx) \leq r \}.$$  

The action of $G$ on $X$ is **proper** if for every $x \in X$ and for every $r \geq 0$, we have $|B_G(x, r)| < \infty$. Let $\eta \geq 0$. The action of $G$ on $X$ is **$\eta$-cobounded** if for every $x, x' \in X$, there exists $g \in G$ such that $d(x, gx') \leq \eta$.

**Definition 2.6 (Path system group).** — Let $\mu \geq 1$, $\nu \geq 0$. A **$(\mu, \nu)$-path system group** $(G, X, \Gamma)$ is a group $G$ acting properly on a geodesic metric space $X$ together with a $G$-invariant collection $\Gamma$ of paths of $X$ such that $(X, \Gamma)$ is a **$(\mu, \nu)$-path system space**.

We fix $\mu \geq 1$, $\nu \geq 0$ and a $(\mu, \nu)$-**path system group** $(G, X, \Gamma)$.

**Definition 2.7 (Quasi-convex subgroup).** — A **subgroup $H \leq G$ is $\eta$-quasi-convex** if there exists an $H$-invariant $\eta$-quasi-convex subset $Y \subseteq X$ such that the action of $H$ on $Y$ is $\eta$-cobounded. We will write $(H, Y)$ when we need to stress the $\eta$-quasi-convex subset $Y$ that $H$ is preserving.

**Definition 2.8 (Constricting element).** — Let $\delta \geq 0$. An **element $g \in G$ is $\delta$-constricting** if the following holds:

(CE1) $g$ has infinite order.

(CE2) There exists a $(g)$-invariant $\delta$-constricting subset $A \subseteq X$ so that the action of $(g)$ on $A$ is $\delta$-cobounded.

We will write $(g, A)$ when we need to stress the $\delta$-constricting subset $A$ that $(g)$ is preserving.

### 3. Growth estimation criteria

In this section, we fix a group $G$ acting properly on a metric space $X$ and a subgroup $H \leq G$. The goal is to establish simple criteria so that we can check if $H$ is a solution to the system of equations

$$\begin{cases}
\omega_H < \omega_G, \\
\omega_{G/H} = \omega_{H\setminus G} = \omega_G.
\end{cases}$$
Our criterion to estimate the relative exponential growth rate is basically [DPPS11, Criterion 2.4]. The statement that we actually need is more specific, so we will give a proof for the convenience of the reader. Recall that a subgroup $H \leq G$ is divergent if its Poincaré series $P_H(s)$ diverges at $s = \omega_H$.

**PROPOSITION 3.1 ([DPPS11, Criterion 2.4]).** — Assume that the following conditions are true:

(I) $\omega_H < \infty$.

(II) $H$ is divergent.

(III) There exist subgroups $K \leq G$ and $F \leq H \cap K$ so that $F$ is a proper finite subgroup of $K$ and the natural morphism $\phi : H * F K \to G$ is injective.

Then $\omega_H < \omega_G$.

**Remark 3.2.** — In the proof below, note that the relative exponential growth rate makes sense for any subset of $G$, as it does the notion of Poincaré series.

**Proof.** — Since $H$ is divergent, in particular it is infinite and hence $H - F$ is non-empty. Since $F$ is a proper subgroup of $K$, there exists $k \in K - F$. Denote by $U$ the set of elements of $H * F K$ that can be written as words that alternate elements of $H - F$ and $k$, always with an element of $H - F$ at the beginning and with a $k$ at the end. The inequality $\omega_{\phi(U)} \leq \omega_G$ can be deduced from the definition. It is enough to prove that there exists $s_0 \geq 0$ such that $\omega_H < s_0 \leq \omega_{\phi(U)}$. Let $o \in X$. Since $\omega_H < \infty$, the interval $(\omega_H, \infty)$ is non-empty. Since $H$ is divergent, there exists $s_0 \in (\omega_H, \infty)$ such that $\sum_{h \in H - F} e^{-sd(o,hko)} > 1$; otherwise one obtains a contradiction with the divergence of $H$.

In order to obtain the inequality $s_0 \leq \omega_{\phi(U)}$, it suffices to show that the Poincaré series $P_{\phi(U)}(s) = \sum_{g \in \phi(U)} e^{-sd(o,gko)}$ diverges at $s = s_0$. Since $\phi : H * F K \to G$ is injective, we have

$$P_{\phi(U)}(s) \geq \sum_{m \geq 1} \sum_{h_1,\ldots,h_m \in H - F} e^{-sd(o,h_1kh_2\cdots h_mko)}.$$

By the triangle inequality, for every $m \geq 1$ and for every $h_1,\ldots,h_m \in H - F$, we have $d(o,h_1kh_2\cdots h_mko) \leq \sum_{i=1}^m d(o,h_i ko)$. Thus,

$$\sum_{h_1,\ldots,h_m \in H - F} e^{-sd(o,h_1kh_2\cdots h_mko)} \geq \left[ \sum_{h \in H - F} e^{-sd(o,hko)} \right]^m.$$

We see that $P(s_0) = \infty$ follows from the claim.

We continue with the quotient exponential growth rates. First, observe this fact:

**PROPOSITION 3.3.** — We have $\omega_{G/H} = \omega_{H\backslash G}$.
Proof. — Let \( \mathcal{L} : G \to G/H \) and \( \mathcal{R} : G \to H \setminus G \) be the natural maps. Let \( x \in X \) and \( r \geq 0 \). We recall that

\[
\mathcal{L}(B_G(x, r)) = \{ gH \in G/H : d(x, gx) \leq r \},
\]
\[
\mathcal{R}(B_G(x, r)) = \{ Hg \in H \setminus G : d(x, gx) \leq r \}.
\]

Note that for every \( g \in G \), we have \( gH \in \mathcal{L}(B_G(x, r)) \) if and only if \( Hg^{-1} \in \mathcal{R}(B_G(x, r)) \). Hence \( |\mathcal{L}(B_G(x, r))| = |\mathcal{R}(B_G(x, r))| \). Therefore \( \omega_{G/H} = \omega_{H \setminus G} \).

Our criterion to estimate the quotient exponential growth rate relies more on the following:

**Definition 3.4.** — Let \( \phi : G \to G \). We say that \( G \) is \( \phi \)-coarsely \( G/H \) if there exist \( \theta \geq 0 \) and \( x \in X \) satisfying the following conditions:

(CQ1) For every \( u, v \in G \), if \( \phi(u)H = \phi(v)H \), then \( d(\phi(u)x, \phi(v)x) \leq \theta \).

(CQ2) For every \( u \in G \), \( d(ux, \phi(u)x) \leq \theta \).

**Proposition 3.5.** — If there exist \( \phi : G \to G \) such that \( G \) is \( \phi \)-coarsely \( G/H \), then \( \omega_G = \omega_{G/H} \).

Proof. — The inequality \( \omega_{G/H} \leq \omega_G \) can be deduced from the definition. Assume that there exist \( \phi : G \to G \) such that \( G \) is \( \phi \)-coarsely \( G/H \) for \( x \in X \) and \( \theta \geq 0 \).

**Claim.** — There exist \( \kappa \geq 1 \) such that for every \( r \geq 0 \),

\[
|B_G(x, r)| \leq \kappa|\mathcal{L}(B_G(x, r + \theta))|.
\]

Let \( \kappa = |B_G(x, 3\theta)| \). Let \( r \geq 0 \). Let \( \hat{\mathcal{L}} : G \to G/H, u \mapsto \phi(u)H \). Note that the ball \( B_G(x, r) \) can be decomposed as the disjoint union of the sets \( \hat{\mathcal{L}}^{-1}(\hat{\mathcal{L}}(u)) \) such that \( \hat{\mathcal{L}}(u) \in \hat{\mathcal{L}}(B_G(x, r)) \). Hence,

\[
|B_G(x, r)| \leq \sum_{\hat{\mathcal{L}}(u) \in \hat{\mathcal{L}}(B_G(x, r))} |\hat{\mathcal{L}}^{-1}(\hat{\mathcal{L}}(u))|.
\]

It suffices to estimate the size of \( \hat{\mathcal{L}}(B_G(x, r)) \) and the size of \( \hat{\mathcal{L}}^{-1}(\hat{\mathcal{L}}(u)) \), for every \( u \in G \). First we prove that \( |\hat{\mathcal{L}}(B_G(x, r))| \leq |\mathcal{L}(B_G(x, r + \theta))| \). Let \( u \in B_G(x, r) \). By the triangle inequality,

\[
d(x, \phi(u)x) \leq d(x, ux) + d(ux, \phi(u)x).
\]

By the hypothesis (CQ2), we have \( d(ux, \phi(u)x) \leq \theta \). Hence \( d(x, \phi(u)x) \leq r + \theta \). Consequently, \( \hat{\mathcal{L}}(B_G(x, r)) \subseteq \hat{\mathcal{L}}(B_G(x, r + \theta)) \). Now we prove that for every \( u \in G \), we have \( |\hat{\mathcal{L}}^{-1}(\hat{\mathcal{L}}(u))| \leq \kappa \). Let \( u \in G \). Since \( |uB_G(x, 3\theta)| = |B_G(x, 3\theta)| = \kappa \), it is enough to prove that \( u^{-1}\hat{\mathcal{L}}^{-1}(\hat{\mathcal{L}}(u)) \subseteq B_G(x, 3\theta) \). Let \( v \in \hat{\mathcal{L}}^{-1}(\hat{\mathcal{L}}(u)) \). By the triangle inequality,

\[
d(x, u^{-1}vx) = d(ux, vx) \leq d(ux, \phi(u)x) + d(\phi(u)x, \phi(v)x) + d(\phi(v)x, vx).
\]
Since \( \hat{L}(u) = \hat{L}(v) \), we have that \( \phi(u)H = \phi(v)H \). It follows from the hypothesis (CQ1) that \( d(\phi(u)x, \phi(v)x) \leq \theta \). By the hypothesis (CQ2), we have \( \max\{d(ux, \phi(u)x), d(vx, \phi(v)x)\} \leq \theta \). Thus, \( d(x, u^{-1}vx) \leq 3\theta \). This proves the claim.

Consequently,
\[
\omega_G \leq \limsup_{r \to \infty} \frac{1}{r} \log |L(B_G(x, r + \theta))|.
\]

Finally, we observe the following,
\[
\limsup_{r \to \infty} \frac{1}{r} \log |L(B_G(x, r + \theta))| = \limsup_{r \to \infty} \frac{r + \theta}{r} \frac{1}{r + \theta} \log |L(B_G(x, r + \theta))| \leq \omega_{G/H}.
\]

\[\square\]

4. Buffering sequences

In this section, we fix constants \( \mu \geq 1, \nu \geq 0 \) and a \((\mu, \nu)\)-path system space \((X, \Gamma)\). Despite the fact that our space \( X \) does not carry any global geometric condition, we still can obtain some control through constricting subsets. We could ignore the «wild regions» if, for instance, we were able to «jump» from one constricting subset to another. The buffering sequences below encapsulate this idea. In fact, the proofs of our main results consist essentially in building up some particular buffering sequences. W. Yang had already introduced this concept for piece-wise geodesics in [Yan19].

**Definition 4.1.** Let \( \delta \geq 0, \varepsilon \geq 0, L \geq 0 \). Let \( A \) be a collection of subsets of \( X \). A finite sequence of subsets \( Y_0, A_1, Y_1, \ldots, A_n, Y_n \subseteq X \) where \( Y_0 \) and \( Y_n \) are the only possible empty sets is \((\delta, \varepsilon, L)\)-buffering on \( A \) if for every \( i \in \{1, \ldots, n\} \) the set \( A_i \) belongs to \( A \) and there exists a \( \delta \)-constricting map \( \pi_{A_i} : X \to A_i \) with the following properties whenever \( Y_i \) and \( Y_{i-1} \) are non-empty:

1. **(BS1)** \( \max\{\text{diam}_{A_i}(A_{i+1}), \text{diam}_{A_{i+1}}(A_i)\} \leq \varepsilon \) if \( i \neq n \).
2. **(BS2)** \( \max\{\text{diam}_{A_i}(Y_{i-1}), \text{diam}_{A_i}(Y_i)\} \leq \varepsilon \).
3. **(BS3)** \( \max\{d(A_i, Y_{i-1}), d(A_i, Y_i)\} \leq \varepsilon \).
4. **(BS4)** \( d_{A_i}(Y_{i-1}, Y_i) \geq L \).

What makes buffering sequences remarkable is that they satisfy a variant of **Behrstock inequality**. We will find a direct application of the following inequality later in the study of the quotient exponential growth rates:

**Proposition 4.2.** Let \( \delta \geq 0, \varepsilon \geq 0, \theta \geq 0 \) with the following property.
Let \( A, Y, B \subseteq X \) be a \((\delta, \varepsilon, 0)\)-buffering sequence on \( \{A, B\} \). Then for every \( x \in X \),
\[
\min\{d_A(x, Y), d_B(x, Y)\} \leq \theta.
\]
Figure 2: An example of a buffering sequence in the Poincaré disk model. In this example, the sets $A_i$ are subpaths of length $\geq L$ of a given bi-infinite geodesic $\alpha$. Each set $Y_i$ is the collection of geodesics that are orthogonal to the geodesic segment of $\alpha$ that is between $A_i$ and $A_{i+1}$. In particular, the sets $Y_i$ are convex. For more intuition, one could interpret this picture on a tree.

**Proof.** — Let $\delta \geq 0$, $\varepsilon \geq 0$. Let $\theta_0 = \theta_0(\delta) \geq 0$ be the constant of Proposition 2.5. Let $\theta \gg \theta_0 + 1$. Its exact value will be precised below. Let $A,Y,B \subseteq X$ be a $(\delta,\varepsilon,0)$-buffering sequence on $\{A,B\}$. Let $x \in X$. By symmetry, it suffices to show that if $d_A(x,Y) > \theta$, then $d_B(x,Y) \leq \theta$. Assume that $d_A(x,Y) > \theta$. Let $a \in A$ such that $d_B(x,a) \leq d_B(x,A) + 1$. Let $b \in B$. Let $y \in Y$. By (BS3), we have $\max\{d(A,Y), d(B,Y)\} \leq \varepsilon$; hence there exist $p \in A^{+\varepsilon+1} \cap Y$ and $q \in B^{+\varepsilon+1} \cap Y$. It follows from the definition of buffering sequence that

$$\max \{d_A(b,\pi_B(q)), d_A(q,p), d_B(a,\pi_A(p)), d_B(p,y)\} \leq \varepsilon.$$ 

Applying together Proposition 2.5 (1) *Coarse nearest-point projection* and (3) *Coarse Lipschitz map*, we obtain

$$\max \{d_A(\pi_B(q),q), d_B(\pi_A(p),p)\} \leq \mu^2(\varepsilon + 1) + \mu \theta_0 + \theta_0.$$ 

**Claim.** — $d_A(x,B) > \theta_0$

By the triangle inequality,

$$d_A(x,b) \geq d_A(x,p) - d_A(b,\pi_B(q)) - d_A(\pi_B(q),q) - d_A(q,p).$$
Moreover, $d_A(x,p) \geq d_A(x,Y)$. Since the element $b$ is arbitrary and $d_A(x,Y) \gg \theta_0 + 1$, we obtain $d_A(x,B) > \theta_0$. This proves the claim.

Finally, we are going to estimate $d_B(x,Y)$. By the triangle inequality,

$$d_B(x,y) \leq d_B(x,a) + d_B(a,\pi_A(p)) + d_B(\pi_A(p),p) + d_B(p,y).$$

Since $d_A(x,B) > \theta_0$, it follows from Proposition 2.5 (5) Behrstock inequality and the definition of $a$ that $d_B(x,a) \leq \theta_0 + 1$. Since the element $y$ is arbitrary, we obtain $d_B(x,Y) \leq \theta$ for $\theta = 2\theta_0 + 1 + 2\varepsilon + \mu^2(\varepsilon + 1) + \mu \theta_0$. 

The corollary below will be applied to the study of the relative exponential growth rates:

**Corollary 4.3.** — For every $\delta \geq 0$, $\varepsilon \geq 0$, $\theta \geq 0$ there exists $L \geq 0$ with the following property. Let $Y_0, A_1, Y_1, \cdots, A_n, Y_n \subseteq X$ be an $(\delta,\varepsilon,L)$-buffering sequence on $\{A_i\}$. Then for every $i \in \{1, \cdots, n\}$,

$$d_{A_i}(Y_0, Y_i) > \theta.$$

**Proof.** — Let $\delta \geq 0$, $\varepsilon \geq 0$, $\theta \geq 0$. Let $\theta_0 = \theta_0(\delta,\varepsilon) \geq 0$ be the constant of Proposition 4.2. We put $L = \theta + \theta_0 + 1$. Let $y_0 \in Y_0$. Let $i \in \{1, \cdots, n\}$.

Claim. — $d_{A_i}(y_0, Y_i) \geq d_{A_i}(Y_{i-1}, Y_i) - d_{A_i}(y_0, Y_{i-1})$.

Let $y_{i-1} \in Y_{i-1}$ and $y_i \in Y_i$. By the triangle inequality,

$$d_{A_i}(y_0, y_i) \geq d_{A_i}(y_{i-1}, y_i) - d_{A_i}(y_0, y_{i-1}).$$

Note that $d_{A_i}(y_{i-1}, y_i) \geq d_{A_i}(Y_{i-1}, Y_i)$. Since the elements $y_{i-1}, y_i$ are arbitrary, this proves the claim.

Finally, we prove by induction on $i \in \{1, \cdots, n\}$ that, $d_{A_i}(Y_0, Y_i) > \theta$. If $i = 1$, then $d_{A_1}(Y_0, Y_1) > \theta$ follows from (BS4), since $L > \theta$. Assume that $i \in \{1, \cdots, n - 1\}$ and $d_{A_i}(Y_0, Y_i) > \theta$. Then $d_{A_i}(y_0, Y_i) > \theta_0$. It follows from Proposition 4.2 that $d_{A_{i+1}}(y_0, Y_i) \leq \theta_0$. By (BS4), $d_{A_{i+1}}(Y_i, Y_{i+1}) \geq L$. Applying the previous claim, we obtain $d_{A_{i+1}}(y_0, Y_{i+1}) > \theta$. Since the element $y_0$ is arbitrary, $d_{A_{i+1}}(Y_0, Y_{i+1}) > \theta$. This concludes the inductive step. 

**5. Quasi-convexity in the Intersection–Image property**

In this section, we fix constants $\mu \geq 1$, $\nu \geq 0$ and a $(\mu,\nu)$-path system space $(X, \Gamma)$. In this section, we prove a variant of Proposition 2.5 (4) Intersection–Image. Basically, we will be exchanging paths of $\Gamma$ for quasi-convex subsets of $X$, further thickening the involved sets.

**Proposition 5.1.** — For every $\delta \geq 0$, $\eta \geq 0$, there exist $\theta \geq 0$ and $\zeta : \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ with the following property. Let $\pi_A : X \to A$ be a $\delta$-constricting map. Let $Y$ be an $\eta$-quasi-
convex subset of $X$. Let $\varepsilon_1 \geq 0$, $\varepsilon_2 \geq 0$. Then

$$| \operatorname{diam}(A^{+\theta+\varepsilon_1} \cap Y^{+\varepsilon_2}) - \operatorname{diam}_A(Y)| \leq \zeta(\varepsilon_1, \varepsilon_2).$$

**Proof.** — Let $\delta \geq 0$, $\eta \geq 0$. Let $\theta_0 = \theta_0(\delta) \geq 0$ be the constant of Proposition 2.5. We put $\theta = \delta + \eta + 1$. Let $\zeta : \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}_{\geq 0}$ depending on $\delta, \eta$. Its exact value will be precised below. Let $\pi_A : X \rightarrow A$ be a $\delta$-constricting map. Let $Y$ be an $\eta$-quasi-convex subset of $X$. Let $\varepsilon_1 \geq 0$, $\varepsilon_2 \geq 0$.

First we prove that $\operatorname{diam}_A(Y) \leq \operatorname{diam}(A^{+\theta+\varepsilon_1} \cap Y^{+\varepsilon_2}) + \zeta(\varepsilon_1, \varepsilon_2)$. Let $x, y \in Y$. It suffices to assume that $d_A(x, y) > \delta$. Let $\gamma \in \Gamma$ joining $x$ to $y$. By (CS2), there exist $p, q \in \gamma$ such that

$$\max\{d(\pi_A(x), p), d(\pi_A(y), q)\} \leq \delta.$$

Since the subset $Y$ is $\eta$-quasi-convex, there exist $p', q' \in Y$ such that

$$\max\{d(p, p'), d(q, q')\} \leq \eta + 1.$$

By the triangle inequality,

$$d_A(x, y) \leq d(\pi_A(x), p) + d(p, p') + d(p', q') + d(q', q) + d(q, \pi_A(y)).$$

Since $p', q' \in A^{+\theta+\varepsilon_1} \cap Y^{+\varepsilon_2}$, we have $d(p', q') \leq \operatorname{diam}(A^{+\theta+\varepsilon_1} \cap Y^{+\varepsilon_2})$. Hence,

$$d_A(x, y) \leq \operatorname{diam}(A^{+\theta+\varepsilon_1} \cap Y^{+\varepsilon_2}) + 2\delta + 2\eta + 1.$$

Now we prove that $\operatorname{diam}(A^{+\theta+\varepsilon_1} \cap Y^{+\varepsilon_2}) \leq \operatorname{diam}_A(Y) + \zeta(\varepsilon_1, \varepsilon_2)$. Let $x, y \in A^{+\theta+\varepsilon_1} \cap Y^{+\varepsilon_2}$. Since $x, y \in Y^{+\varepsilon_2}$, there exist $x', y' \in Y$ such that $\max\{d(x, x'), d(y, y')\} \leq \varepsilon_2 + 1$. By the triangle inequality,

$$d(x, y) \leq d(x, \pi_A(x)) + d_A(x, x') + d_A(x', y') + d_A(y', y) + d(\pi_A(y), y).$$

Since $x, y \in A^{+\theta+\varepsilon_1}$, it follows from Proposition 2.5 (1) **Coarse nearest-point projection** that

$$\max\{d(x, \pi_A(x)), d(y, \pi_A(y))\} \leq \mu(\theta + \varepsilon_1) + \theta_0.$$

It follows from Proposition 2.5 (3) **Coarse Lipschitz Map** that,

$$\max\{d_A(x, x'), d_A(y, y')\} \leq \mu(\varepsilon_2 + 1) + \theta_0.$$

Since $\pi_A(x'), \pi_A(y') \in \pi_A(Y)$, we have $d_A(x', y') \leq \operatorname{diam}_A(Y)$. Hence,

$$d(x, y) \leq \operatorname{diam}_A(Y) + 2\mu(\theta + \varepsilon_1) + 2\mu(\varepsilon_2 + 1) + 4\theta_0.$$
Finally, we put $\zeta(\varepsilon_1, \varepsilon_2) = \max \{2\delta + 2\eta + 1, 2\mu(\theta + \varepsilon_1) + 2\varepsilon_2 + 1 + 4\theta_0\}$. \hfill \Box

Applying the symmetry of Proposition 5.1 in combination with Proposition 2.5 (6) Morse-ness and (7) Coarse invariance, we deduce:

**Corollary 5.2.** — For every $\delta \geq 0$, there exists $\theta \geq 0$ with the following property. Let $\pi_A \colon X \to A$ and $\pi_B \colon X \to B$ be $\delta$-constricting maps. Then:

$$|\text{diam}_A(B) - \text{diam}_B(A)| \leq \theta.$$

### 6. Finding a quasi-convex element

Given a torsion-free hyperbolic group $G$ containing a loxodromic element $g_0$ and an infinite index quasi-convex subgroup $H$, one can find another loxodromic element $g \in G$ conjugate to $g_0$ so that $H$ has trivial intersection with $\langle g \rangle$ [Arz01, Theorem 1]. The goal of this section is to reimplement this fact in our setting, using a «quasi-convex element» instead of a loxodromic element. In this section, we fix constants $\mu \geq 1$, $\nu \geq 0$ and a $(\mu, \nu)$-path system group $(G, X, \Gamma)$.

**Definition 6.1 (Quasi-convex element).** — Let $\eta \geq 0$. An element $g \in G$ is $\eta$-quasi-convex if the following holds:

- (QE1) $g$ has infinite order.
- (QE2) $\langle g \rangle$ is an $\eta$-quasi-convex subgroup of $G$.

We will write $(g, A)$ when we need to stress the $\eta$-quasi-convex subset $A$ that $\langle g \rangle$ is preserving.

The main result of this section is the following.

**Proposition 6.2.** — Let $\eta \geq 0$. Assume that $G$ contains an $\eta$-quasi-convex element $(g, A)$. There exists $\theta = \theta(\eta, g, A) \geq 1$ satisfying the following. Let $(H, Y)$ be an $\eta$-quasi-convex subgroup of $G$. Then:

1. (I) For every $u \in G$, if $\text{diam}(uA \cap Y) > \theta$, then $uA \subseteq Y^+\theta$.
2. (II) Let $H \leq K \leq G$. If $[K : H] > \theta$, then there exist $k \in K$ such that $\text{diam}(kA \cap Y) \leq \theta$.

**Remark 6.3.** — Under the notation of (II), when $K = G$, the element $kgk^{-1}$ has the desired property that we were looking for. Note that $(kgk^{-1}, kA)$ is quasi-convex since $\Gamma$ is $G$-invariant.

The rest of the section is devoted to the proof of Proposition 6.2.

**Definition 6.4.** — Let $\kappa \geq 1$, $\lambda \geq 0$. A map $\phi \colon (Y, d_Y) \to (Z, d_Z)$ between two metric spaces is a $(\kappa, \lambda)$-quasi-isometric embedding if for every $y, y' \in Y$,

$$\frac{1}{\kappa}d_Y(y, y') - \lambda \leq d_Z(\phi(y), \phi(y')) \leq \kappa d_Y(y, y') + \lambda.$$
We start with a variant of Milnor-Schwarz Theorem. If $U$ is a generating set of a group $H$, we denote by $d_U$ the word metric of $H$ with respect to $U$.

**Lemma 6.5.** For every $\eta \geq 0$, there exist $\theta \geq 1$ with the following property. Let $(H,Y)$ be an $\eta$-quasi-convex subgroup of $G$. For every $y \in Y$, there exists a finite generating set $U$ of $H$ such that the orbit map $(H,d_U) \to X$, $h \mapsto hy$ is a $(\theta,\theta)$-quasi-isometric embedding.

For the proof, one can use the same kind of argument as that of Milnor-Schwarz Theorem, but bearing in mind that $Y$ might not be a length metric space, which is required by the original statement. The only difference here is that one uses the paths of $\Gamma$ with endpoints in $Y$. They are enough for the proof since they approximate sufficiently well the distances, at least in this situation.

**Lemma 6.6.** Let $\eta \geq 0$. Let $H \leq G$ be an abelian subgroup. Let $Y \subseteq X$ be an $H$-invariant subset so that the action of $H$ on $Y$ is $\eta$-cobounded. Then, for every $h \in H$ and for every $y,z \in Y$,

$$|d(y,hy) - d(z,hz)| \leq 2\eta.$$

**Proof.** Let $h \in H$. Let $y,z \in Y$. Since the action of $H$ on $Y$ is $\eta$-cobounded, there exists $k \in H$ such that $d(z,ky) \leq \eta$. By the triangle inequality,

$$d(y,hy) \leq d(ky,khy) \leq d(ky,z) + d(z,hz) + d(hz,khy).$$

Since the subgroup $H$ is abelian, $d(hz,khy) = d(z,ky)$. Thus, $d(y,hy) \leq d(z,hz) + 2\eta$. Finally, exchanging the roles of $y$ and $z$, we obtain $d(y,hy) \geq d(z,hz) - 2\eta$.

Next, we are going to check that we can obtain uniform quasi-isometric embeddings of $\mathbb{Z}$ in $X$ via the orbit maps of quasi-convex elements of $G$ that share the same constant. For this reason, we introduce the following definition:

**Definition 6.7.** Let $g \in G$. The **asymptotic translation length** of $g$ is

$$[g]^\infty = \limsup_{m \to \infty} \frac{1}{m} d(o, g^m o).$$

Note that $[g]^\infty$ does not depend on the choice of the point $o \in X$.

**Remark 6.8.** Let $g \in G$. By subadditivity, for every $o \in X$, we have

$$[g]^\infty = \inf_{m \geq 1} \frac{1}{m} d(o, g^m o) = \lim_{m \to \infty} \frac{1}{m} d(o, g^m o).$$

**Lemma 6.9.** Let $\eta \geq 0$. Let $g \in G$. Let $A \subseteq X$ be a $\langle g \rangle$-invariant subset so that the action of $\langle g \rangle$ on $A$ is $\eta$-cobounded. The following statements are equivalent:

(I) There exists $x \in X$ such that the orbit map $\mathbb{Z} \to X$, $m \mapsto g^m x$ is a quasi-isometric embedding.
(II) $|g|^\infty > 0$.

(III) There exists $\theta = \theta(\eta, g, A) \geq 1$ such that for every $a \in A$, the orbit map $\mathbb{Z} \to X$, $m \mapsto g^m a$ is a $(\theta, 0)$-quasi-isometric embedding.

Proof. — The implication $(III) \Rightarrow (I)$ already holds.

$(I) \Rightarrow (II)$. Assume that there exists $x \in X$ such that the orbit map $\mathbb{Z} \to X$, $m \mapsto g^m x$ is a quasi-isometric embedding. Then there exist $\kappa \geq 1$, $\lambda \geq 0$ such that for every $m \geq 1$,

$$\frac{1}{\kappa} - \frac{\lambda}{m} \leq \frac{1}{m} d(x, g^m x) \leq \kappa + \frac{\lambda}{m}.$$ 

Therefore, $|g|^\infty \geq \frac{1}{\kappa} > 0$.

$(II) \Rightarrow (III)$. Assume that $|g|^\infty > 0$. Let $|g|_A = \inf_{a \in A} d(a, ga)$. Then we can define $\theta = \max \left\{ |g|_A + 2\eta, \frac{1}{|g|^\infty}, 1 \right\}$. Let $a \in A$. Applying the triangle inequality we obtain that for every $m \in \mathbb{Z}$, $d(a, g^m a) \leq d(a, ga)|m|$. It follows from Lemma 6.6 that $d(a, ga) \leq |g|_A + 2\eta$. Since $|g|^\infty = \inf_{n \in \mathbb{N} - \{ 0 \} \frac{1}{m} d(a, g^m a)$, we obtain that for every $m \in \mathbb{Z}$, $d(a, g^m a) \geq |g|^\infty |m|$. Hence the orbit map $\mathbb{Z} \to X$, $m \mapsto g^m a$ is a $(\theta, 0)$-quasi-isometric embedding.

Lemma 6.10. — Let $\eta \geq 0$. Let $(g, A)$ be an $\eta$-quasi-convex element of $G$. There exists $\theta = \theta(\eta, g, A) \geq 1$ such that for every $a \in A$, the orbit map $\mathbb{Z} \to X$, $m \mapsto g^m a$ is a $(\theta, 0)$-quasi-isometric embedding. Moreover, $|g|^\infty > 0$.

Proof. — We are going to apply Lemma 6.5 and Lemma 6.9. Let $a \in A$. According to Lemma 6.5, there exist a finite generating set $U$ of $(g)$ such that the orbit map $\phi : (g : d_U) \to X$, $h \mapsto ha$ is a quasi-isometric embedding. Furthermore, since $g$ has infinite order, the map $\chi : \mathbb{Z} \to (g)$, $m \mapsto g^m$ is an isomorphism. Let $V = \chi^{-1}(U)$. In particular $\chi : (\mathbb{Z}, d_V) \to (g : d_U)$ is an isometry. Moreover, the map $\psi : \mathbb{Z} \to (\mathbb{Z}, d_V)$ is a quasi-isometric embedding. Hence, the composition $\phi \circ \chi \circ \psi$ is a quasi-isometric embedding. Now both of the statements of the lemma follow from Lemma 6.9.

We continue by upper bounding the length of a quasi-geodesic of $X$ by the number of points of an orbit of a subgroup $H$ of $G$ that fall inside a precise neighbourhood of this quasi-geodesic, whenever the quasi-geodesic falls also inside a neighbourhood of that orbit.

Lemma 6.11. — For every $\eta \geq 0$, $\kappa \geq 1$, $\lambda \geq 0$, there exists $\theta \geq 1$ with the following property. Let $H \leq G$. Let $Y \subseteq X$ be an $H$-invariant subset such that the action of $H$ on $Y$ is $\eta$-cobounded. Let $y \in Y$. Let $\gamma$ be a $(\kappa, \lambda)$-quasi-geodesic of $X$ such that $\gamma \subseteq Y^+\eta$. Let $U = \{ u \in H : uy \in \gamma^{+2\eta+1} \}$. Then

$$\ell(\gamma) \leq \theta |U|.$$ 

Proof. — Let $\eta \geq 0$, $\kappa \geq 1$, $\lambda \geq 0$. Let $\theta = \theta(\eta, \kappa, \lambda) \geq 1$. Its exact value will be precised below. Let $H, Y, y, \gamma : [0, L] \to X$ and $U$ as in the statement. Let $m = \left\lfloor \frac{L}{\theta} \right\rfloor + 1$. We fix a partition $0 = t_0 \leq t_1 \leq \cdots \leq t_m = L$ of $[0, L]$ such that $|t_{m-1} - t_m| \leq \theta$ and such that if $m \geq 2$, $\ell(\gamma) \leq \theta |U|$.
then for every $i \in \{0, \ldots, m-2\}$, we have $|t_i - t_{i+1}| = \theta$. Hence $\ell(\gamma) = L \leq \theta m$. We prove that $m \leq |U|$. Let $i \in \{0, \ldots, m-1\}$. Denote $x_i = \gamma(t_i)$. Since the action of $H$ on $Y$ is $\eta$-cobounded and $\gamma \subseteq Y^+$, for every $i \in \{0, \ldots, m-1\}$, there exists $h_i \in H$ such that $d(x_i, h_i y) \leq 2\eta + 1$. In particular, $h_i \in U$. From now on we may assume that $m \geq 2$, otherwise there is nothing to show. Let $i, j \in \{0, \ldots, m-1\}$ such that $i \neq j$. We claim that $h_i \neq h_j$. The claim will follow when we show that $d(h_i y, h_j y) > 0$. By the triangle inequality,

$$d(h_i y, h_j y) \geq d(x_i, x_j) - d(x_i, h_i y) - d(x_j, h_j y).$$

Since $\gamma$ is a $(\kappa, \lambda)$-quasi-geodesic,

$$d(x_i, x_j) \geq \frac{1}{\kappa} |t_i - t_j| - \frac{\lambda}{\kappa}. $$

Since $i, j \in \{0, \ldots, m-1\}$, we have that $|t_i - t_j| \geq \theta$. To sum up,

$$d(h_i y, h_j y) \geq \frac{\theta}{\kappa} - \frac{\lambda}{\kappa} - 2\eta - 2.$$

Finally, we put $\theta = \kappa \left(\frac{\lambda}{\kappa} + 4\eta + 2\right) + 1$. Hence, $d(h_i y, h_j y) > 0$. In particular, we obtain $m \leq |U|$.

The following fact is a direct consequence of the triangle inequality:

**Lemma 6.12.** — Let $\eta \geq 0$. Let $H \leq G$. Let $Y \subseteq X$ be an $H$-invariant subset so that the action of $H$ on $Y$ is $\eta$-cobounded. Then, for every $y, z \in Y$, there exists $h \in H$ such that for every $r \geq 0$,

$$h^{-1} B_G(y, r) h \subseteq B_G(z, r + 2\eta).$$

Finally, we show that there is a uniform threshold that ensures the existence of a uniformly short element in the intersection of any pair of quasi-convex subgroups of $G$ that share the same constant.

**Lemma 6.13.** — For every $\eta \geq 0$, there exists $\theta \geq 1$ with the following property. Let $(H, Y)$ and $(K, Z)$ be $\eta$-quasi-convex subgroups of $G$. If $\text{diam}(Y \cap Z) > \theta$, then there exist $y \in Y \cap Z$ and $h \in H \cap K \cap B_G(y, \theta) - \{1_G\}$.

**Proof.** — Let $\eta \geq 0$. Let $\theta_0 = \theta_0(\eta, \mu, \nu) \geq 1$ be the constant of Lemma 6.11. Let $o \in Y$. We denote $W = B_G(o, 6\eta + 2)$. Let $\theta_1 = \theta_0|W| + \theta_0$. Note that the constant $\theta_1$ is finite since the action of $G$ on $X$ is proper. We put $\theta = 2\theta_1 + 4\eta + 2$. Let $(H, Y)$ and $(K, Z)$ be $\eta$-quasi-convex subgroups of $G$. Assume that $\text{diam}(Y \cap Z) > \theta$. Since $\text{diam}(Y \cap Z) > \theta_1$, there exist $y, z \in Y \cap Z$ such that $d(y, z) > \theta_1$. Let $\beta \in \Gamma$ joining $y$ to $z$. Since $\ell(\beta) > \theta_1$, there exist $z' \in \beta$ and a subpath $\gamma$ of $\beta$ joining $y$ to $z'$ such that $\ell(\gamma) = \theta_1$. We denote $U = \{u \in H : uy \in \gamma^{2\eta + 1}\}$ and $V = B_G(y, 4\eta + 2)$. 
The first step is to construct a map $\phi: U \to V$. Let $u \in U$. By definition of $U$, there exists $x \in \gamma$ such that $d(uy,x) \leq 2\eta + 1$. Since the subgroup $(K,Z)$ is $\eta$-quasi-convex, there exists $k_u \in K$ such that $d(x,k_u y) \leq 2\eta + 1$. By the triangle inequality,

$$d(uy,k_u y) \leq d(uy,x) + d(x,k_u y).$$

Consequently, $d(u^{-1}k_u y,y) \leq 4\eta + 2$. Hence, $u^{-1}k_u \in V$. We define $\phi: U \to V$ to be the map that sends every $u \in U$ to $u^{-1}k_u \in V$.

Next, we show that the map $\phi: U \to V$ is not injective. Since $Y$ is $\eta$-quasi-convex, we have that $\gamma \leq \beta \leq Y^\eta$. It follows from Lemma 6.11 that $|U| \geq \frac{1}{\theta_0} \ell(\gamma)$. By hypothesis, $\ell(\gamma) = \theta_0 |W| + \theta_0$. Since the action of $H$ on $Y$ is $\eta$-cobounded, it follows from Lemma 6.12 that there exists $h \in H$ such that $h^{-1}Vh \subseteq W$ and hence $|W| \geq |h^{-1}Vh| = |V|$. Consequently, $|U| > |V|$. Therefore, the map $\phi: U \to V$ is not injective.

Now we claim that $U \subseteq B_G(y,\theta_1 + 2\eta + 1)$. Let $u \in U$. By definition of $U$, there exists $x \in \gamma$ such that $d(x,uy) \leq 2\eta + 1$. By the triangle inequality,

$$d(y,uy) \leq d(y,x) + d(x,uy).$$

Moreover, $d(y,x) \leq \ell(\gamma) = \theta_1$. Hence $d(y,uy) \leq \theta_1 + 2\eta + 1$.

Finally, since the map $\phi: U \to V$ is not injective, there exist $u_1,u_2 \in U$ such that $u_1 \neq u_2$ and $u_1^{-1}k_{u_1} = u_2^{-1}k_{u_2}$. In particular, $u_2u_1^{-1} \in H \cap K - \{1_G\}$. Further, according to the triangle inequality,

$$d(y,u_2u_1^{-1}y) \leq d(y,u_2y) + d(u_2y,u_2u_1^{-1}y).$$

It follows from the claim above that $d(y,u_2u_1^{-1}y) \leq \theta$. Therefore, $u_2u_1^{-1} \in H \cap K \cap B_G(y,\theta) - \{1_G\}$. 

We are ready to prove the proposition:

**Proof of Proposition 6.2.** — Let $\eta > 0$. Assume that $G$ contains an $\eta$-quasi-convex element $(g,A)$. We are going to determine the value of $\theta = \theta(\eta,g,A) \geq 1$. By Lemma 6.10, there exists $\theta_0 = \theta_0(\eta,g,A) \geq 1$ such that for every $a \in A$, the orbit map $Z \to X$, $m \mapsto g^ma$ is a $(\theta_0,0)$-quasi-isometric embedding. Let $\theta_1 = \theta_1(\eta) \geq 1$ be the constant of Lemma 6.13. Let $\theta_2 = \eta + \theta_0^2 \theta_1$. Let $o \in A$. We denote $U = B_G(o,2\theta_2 + \eta + 1)$. Let $\theta = \max \{\theta_2,|U|\}$. Note that the constant $\theta$ is finite since the action of $G$ on $X$ is proper. Let $(H,Y)$ be an $\eta$-quasi-convex subgroup of $G$.

(I) Let $u \in G$. Assume that $\text{diam}(uA \cap Y) > \theta$. Let $a \in A$. We prove that $ua \in Y^{+\theta_2}$. Since $\Gamma$ is $G$-invariant, the element $(ugr^{-1},uA)$ is $\eta$-quasi-convex. Since $\text{diam}(uA \cap Y) > \theta_1$, according to Lemma 6.13, there exist $b \in A$ and $M \in Z - \{0\}$ such that $ub \in uA \cap Y$ and $ug^{mb^{-1}} \in H \cap B_G(ub,\theta_1)$. Since the action of $\langle g \rangle$ on $A$ is $\eta$-cobounded, there exists $m \in Z$ such that $d(a,g^{mb}) \leq \eta$. By Euclid’s division Lemma, there exist $q,r \in \mathbb{Z}$ such
that \( m = qM + r \) and \( 0 \leq r \leq |M| - 1 \). By the triangle inequality,
\[
d(ua, Y) \leq d(ua, ug^M b) + d(ug^m b, ug^M b)
\]
Note that \( d(ua, ug^m b) = d(a, g^m b) \leq \eta \). Moreover, it follows from Lemma 6.10 that
\[
d(ug^m b, ug^M b) = d(g^rb, b) \leq \theta_0 |r|.
\]
Note also that \( |r| \leq |M| \). Applying again Lemma 6.10, we obtain that
\[
|M| \leq \theta_0 d(g^M b, b).
\]
By Lemma 6.13,
\[
d(g^M b, b) = d(u g^M u^{-1} ub, ub) \leq \theta_1.
\]
Hence,
\[
d(ua, Y) \leq \theta_2 \leq \theta.
\]

(II) Let \( H \leq K \leq G \). We argue by contraposition. Assume that for every \( k \in K \), we have \( \text{diam}(kA \cap Y) > \theta \). We prove that \( [K : H] \leq |U| \). It follows from (I) that \( KA \subseteq Y^{+\theta_2} \). Then there exists \( y \in Y \) such that \( d(o, y) \leq \theta_2 + 1 \). Since the action of \( H \) on \( Y \) is \( \eta \)-cobounded, we have that \( Y \subseteq (Hy)^{+\eta} \). Hence \( Ko \subseteq (Hy)^{+\theta_2 + \eta} \). In particular, for every \( k \in K \), there exists \( h_k \in H \) such that \( d(k o, h_k y) \leq \theta_2 + \eta \). Let \( K' \) be a set of representatives of the set \( H \setminus K \) of right cosets of \( H \). Then the set \( K'' = \{ h_k^{-1}k : k \in K' \} \) is a set of representatives of \( H \setminus K \). We claim that \( K'' \subseteq U \). Let \( k \in K' \). By the triangle inequality,
\[
d(h_k^{-1}k o, o) = d(k o, h_k o) \leq d(k o, h_k y) + d(h_k y, h_k o).
\]
Thus, \( d(h_k^{-1}k o, o) \leq 2\theta_2 + \eta + 1 \). This proves the claim. Consequently,
\[
[K : H] \leq |K''| \leq |U| \leq \theta.
\]

7. Constricting elements

In this section, we fix constants \( \mu \geq 1, \nu \geq 0, \delta \geq 0 \) and a \((\mu, \nu)\)-path system group \((G, X, \Gamma)\). We assume that \( G \) contains a \( \delta \)-constricting element \((g, A)\) with associated \( \delta \)-constricting map \( \pi_A : X \to A \).

7.1. A \( G \)-invariant family

The set of \( G \)-translates of \( A \) is a \( G \)-invariant family of \( \delta \)-constricting subsets. Indeed, consider the stabilizer \( \text{Stab}(A) \) of \( A \) and fix a set \( R_g \) of representatives of \( G / \text{Stab}(A) \). Let \( u \in G \) and \( u_0 \in R_g \) such that \( uA = u_0 A \). The map \( \pi_{uA} : X \to uA \) defined as
\[
\forall x \in X, \quad \pi_{uA}(x) = u_0 \pi_A(u_0^{-1} x).
\]
is then $\delta$-constricting since $\Gamma$ is $G$-invariant. Moreover, the element $(ugu^{-1}, uA)$ is $\delta$-constricting. To cope with the possible lack of $\langle ugu^{-1} \rangle$-equivariance of the map $\pi_{uA} : X \to uA$, we make the following observation:

**Proposition 7.1.** — There exists $\theta \geq 0$ satisfying the following. Let $u \in G$. Then:

(I) For every $x \in X$, we have $d(\pi_{uA}(x), u\pi_A(u^{-1} x)) \leq \delta$.

(II) For every $Y \subseteq X$, we have $|\text{diam}_{uA}(Y) - \text{diam}(u\pi_A(u^{-1} Y))| \leq \theta$.

**Proof.** — Let $\theta_0 = \theta_0(\delta) \geq 0$ be the constant of Proposition 2.5. We put $\theta = 2\theta_0$. Let $u \in G$.

(I) Let $x \in X$. Denote $y = u^{-1}x$. Let $u_0 \in R_g$ such that $uA = u_0 A$. We see that,

$$d(\pi_{uA}(x), u\pi_A(u^{-1} x)) = d(u_0 \pi_A(u_0^{-1} x), u\pi_A(u^{-1} x)) = d(\pi_A(u_0^{-1} uy), u_0^{-1}u\pi_A(y)).$$

Since $u_0^{-1} u \in \text{Stab}(A)$, it follows from Proposition 2.5 (2) Coarse equivariance that $d(\pi_{uA}(x), u\pi_A(u^{-1} x)) \leq \theta_0$.

(II) Let $Y \subseteq X$. Let $y, y' \in Y$. By the triangle inequality,

$$|d(\pi_A(y), \pi_{uA}(y')) - d(u\pi_A(u^{-1} y), u\pi_A(u^{-1} y'))| \leq$$

$$d(\pi_A(y), u\pi_A(u^{-1} y)) + d(u\pi_A(u^{-1} y'), \pi_{uA}(y')).$$

It follows from (I) that

$$\max \{d(u\pi_{uA}(y), u\pi_A(u^{-1} y)), d(u\pi_A(u^{-1} y'), \pi_{uA}(y'))\} \leq \theta_0.$$

Hence, we have $|\text{diam}_{uA}(Y) - \text{diam}(u\pi_A(u^{-1} Y))| \leq 2\theta_0$.

7.2. Finding a constricting element

The goal of this subsection is to combine Proposition 6.2 and Proposition 5.1. We suggest to compare (II) below with the property (BS2) of the buffering sequences.

**Proposition 7.2.** — Let $\eta \geq 0$. There exists $\theta \geq 1$ satisfying the following. Let $(H,Y)$ be an $\eta$-quasi-convex subgroup of $G$. Then:

(I) For every $u \in G$, if $\text{diam}_{uA}(Y) > \theta$, then $uA \subseteq Y^+\theta$.

(II) Let $H \leq K \leq G$. If $|K : H| > \theta$, then there exists $k \in K$ such that $\text{diam}_{kA}(Y) \leq \theta$.

26
Proof. — Let $\eta \geq 0$. Let $\theta = \theta(\eta) \geq 1$. Its exact value will be precised below. It follows from Proposition 2.5 (6) Morseness and (7) Coarse invariance that there exists $\theta_0 \geq 0$ such that the element $(g, A)$ is $\theta_0$-quasi-convex. Let $\theta_1 = \max \{\eta, \theta_0\}$. By Proposition 5.1, there exist $\theta_2 \geq 0$, $\zeta \geq 0$ depending both on $\theta_1$ such that for every $u \in G$ and for every $\theta_1$-quasi-convex subset $Y \subseteq X$, we have

$$diam_u \cdot A(Y) - \zeta \leq diam(u \cdot A^{+\theta_2} \cap Y) \leq diam_u \cdot A(Y) + \zeta.$$ 

According to Proposition 2.5 (6) Morseness and (7) Coarse invariance, there exist $\theta_3 = \theta_3(\theta_2) \geq 0$ such that the element $(g, A^{+\theta_2})$ is $\theta_3$-quasi-convex. Let $\theta_4 = \max \{\eta, \theta_3\}$. Let $\theta_5 = \theta_5(\theta_4, g, A) \geq 1$ be the constant of Proposition 6.2. Finally, we put $\theta = \theta_5 + \zeta$. Let $(H, Y)$ be an $\eta$-quasi-convex subgroup of $G$.

(I) Let $u \in G$. Assume that $diam_u \cdot A(Y) > \theta$. According to Proposition 5.1, we have $diam(u \cdot A^{+\theta_2} \cap Y) > \theta_5$ and according to Proposition 6.2 (I) this implies that $u \cdot A \subseteq Y^{+\theta_5} \subseteq Y^{+\theta}$.

(II) Let $H \leq K \leq G$. We argue by contraposition. Assume that for every $k \in K$, we have $diam_k \cdot A(Y) > \theta$. According to Proposition 5.1, for every $k \in K$, we have $diam(k \cdot A^{+\theta_2} \cap Y) > \theta_5$ and according to Proposition 6.2 (II) this implies that $[K : H] \leq \theta_5 \leq \theta$.

$\square$

7.3. Elementary closures

The elementary closure of $(g, A)$ could be thought as the set of elements $u \in G$ such that $u \cdot A$ is «parallel» to $A$:

**Definition 7.3.** — The elementary closure of $(g, A)$ in $G$ is defined as

$$E(g, A) = \{u \in G: d_{Haus}(u \cdot A, A) < \infty\}.$$ 

Observe that $E(g, A)$ is a subgroup of $G$ since $d_{Haus}$ is a pseudo-distance.

This subsection is devoted to provide a further description $E(g, A)$. We suggest to compare the proposition below with the property (BS1) of the buffering sequences.

**Proposition 7.4.** — There exists $\theta \geq 1$ satisfying the following:

(I) For every $u \in G$, we have

$$\max \{diam_u \cdot A(A), diam(A)\} > \theta \iff d_{Haus}(u \cdot A, A) \leq \theta.$$ 

(II) $E(g, A) = \{u \in G: d_{Haus}(u \cdot A, A) \leq \theta\}$. 

---

27
(III) \[ E(g, A) : \langle g \rangle \leq \theta. \]

**Proof.** — Let \( \theta_0 \geq 0 \) be the constant of Proposition 7.1. According to Proposition 2.5 (6) Morseness, there exists \( \theta_1 \geq 0 \) such that the element \((g, A)\) is \(\theta_1\)-quasi-convex. Let \( \theta_2 = \theta_2(\theta_1) \geq 1 \) be the constant of Proposition 7.2. We put \( \theta = \theta_0 + \theta_2 \).

**Claim.** — Let \( u \in G \). If \( d_{Haus}(uA, A) < \infty \), then \( \text{diam}_{uA}(A) = \infty \).

Let \( u \in G \). Assume that \( d_{Haus}(uA, A) < \infty \) and denote \( \varepsilon = d_{Haus}(uA, A) + 1 \). By Proposition 5.1, there exist \( \theta_3 \geq 0, \zeta \geq 0 \) such that for every \( u \in G \) we have

\[
\text{diam}_{uA}(A) - \zeta \leq \text{diam}(uA^{\theta_3} \cap A^{+\varepsilon}) \leq \text{diam}_{uA}(A) + \zeta.
\]

Note that \( uA \subseteq uA^{\theta_3} \cap A^{+\varepsilon} \) and \( \text{diam}(uA) = \text{diam}(A) \). Since the action of \( G \) on \( X \) is proper and since the element \( g \) has infinite order, we have that \( \text{diam}(A) = \infty \). Consequently, we have \( \text{diam}(uA^{\theta_3} \cap A^{+\varepsilon}) = \infty \). Finally, it follows from Proposition 5.1 that \( \text{diam}_{uA}(A) = \infty \). This proves the claim.

(I) Let \( u \in G \). Assume that \( \max \{ \text{diam}_{uA}(A), \text{diam}_{A}(uA) \} > \theta \). By Proposition 7.1,

\[
\text{diam}_{u^{-1}A}(A) \geq \text{diam}_{A}(u^{-1} \pi_A(uA)) - \theta_0.
\]

Hence, \( \text{diam}_{u^{-1}A}(A) > \theta_2 \). It follows from Proposition 7.2 (I) that \( uA \subseteq A^{+\theta} \) and \( u^{-1}A \subseteq A^{+\theta} \). Hence \( d_{Haus}(uA, A) \leq \theta \). The converse follows from the claim above.

(II) This follows from (I) and the claim above.

(III) This follows from (I), (II) and Proposition 7.2 (II).

\[ \square \]

Finally, we obtain an algebraic description of \( E(g, A) \).

**Corollary 7.5.** — There exist \( \theta \geq 1 \) and \( M \in [1, \theta] \cap \mathbb{N} \) such that for every \( u \in G \), the following statements are equivalent:

(I) \( u \in E(g, A) \).

(II) There exists \( p \in \{-1, 1\} \) such that \( ug^M u^{-1} = g^p M \).

(III) There exist \( m, n \in \mathbb{Z} \) such that \( ug^m u^{-1} = g^n \).

Further, let \( E^+(g, A) = \{ u \in G : ug^M u^{-1} = g^M \} \). Then \( [E(g, A) : E^+(g, A)] \leq 2 \).

**Proof.** — By Proposition 7.4 (II), there exists \( \theta_0 \geq 1 \) such that \( [E(g, A) : \langle g \rangle] \leq \theta_0 \). Let \( \theta = \theta_0! \) We construct \( M \in [1, \theta] \cap \mathbb{N} \). First, we claim that there exists a subgroup
Hence, \[ M \leq \langle g \rangle \] such that \( K \leq E(g, A) \) and \([ E(g, A) : K ] \leq \theta\). Consider the natural action of \( E(g, A) \) by right multiplication on the set \( \langle g \rangle \backslash E(g, A) \) of right cosets of \( \langle g \rangle \). This gives an homomorphism \( \phi: E(g, A) \to Sym(\langle g \rangle \backslash E(g, A)) \). Choose \( K = \text{Ker}(\phi) \). Note that \( \langle g \rangle = \{ h \in E(g, A) : \phi(h)(\langle g \rangle) = \langle g \rangle \} = \langle g \rangle \). Thus, \( K \leq \langle g \rangle \). Moreover, \( K \leq E(g, A) \). Further, we have that \( |Sym(\langle g \rangle \backslash E(g, A))| = |E(g, A) : \langle g \rangle| \) and hence \( |E(g, A) : K| \) divides \( |E(g, A) : \langle g \rangle| \). Therefore, \( |E(g, A) : K| \leq \theta \). This proves the claim. Now, since the element \( g \) has infinite order, the subgroup \( E(g, A) \) is infinite. Hence, since \( |E(g, A) : K| < \infty \) there exists \( M \in \mathbb{N}_+ \) such that \( K = \langle g^M \rangle \). Finally, we remark that \( M \) is equal to the order of the element \( \phi(g) \). Hence, \( M \leq \theta \).

Let \( u \in G \). The implication \((II) \Rightarrow (III)\) already holds. 

\((I) \Rightarrow (II)\). Assume that \( u \in E(g, A) \). Since the subgroup \( \langle g^M \rangle \) is normal in \( E(g, A) \), there exists \( p \in \mathbb{Z} \) such that \( u g^M u^{-1} = g^p M \). In particular,

\[ \langle g^M \rangle = u \langle g^M \rangle u^{-1} = \langle u g^M u^{-1} \rangle = \langle g^p M \rangle. \]

Hence, if \( p \in \{ -1, +1 \} \), then \( \langle g^M \rangle \not\leq \langle g^p M \rangle \). Contradiction.

\((III) \Rightarrow (I)\). Assume that there exist \( m, n \in \mathbb{Z} - \{ 0 \} \) such that \( u g^m u^{-1} = g^n \). Since both \( \langle g^m \rangle \) and \( \langle g^n \rangle \) have finite index in \( \langle g \rangle \), there exist \( \zeta \geq 0 \) the actions of \( \langle u g^m u^{-1} \rangle \) on \( uA \) and of \( \langle g^n \rangle \) on \( A \) are both \( \zeta \)-cobounded. Let \( x \in uA \) and \( y \in A \). We obtain \( d_{\text{Haus}}(uA, A) \leq \zeta + d(x, y) \). Hence \( d_{\text{Haus}}(uA, A) < \infty \).

Finally, let \( E^+(g, A) = \{ u \in G : u g^M u^{-1} = g^M \} \). We prove that \( |E(g, A) : E^+(g, A)| \leq 2 \). It is enough to assume that \( E(g, A) \neq E^+(g, A) \). Let \( u, v \in E(g, A) - E^+(g, A) \). We show that \( v^{-1} u \in E^+(g, A) \). Since \( u g^M u^{-1} = v g^M v^{-1} = g^{-M} \), we have \( v^{-1} u g^M u^{-1} v = v^{-1} g^{-M} v = g^M \) and therefore \( v^{-1} u \in E^+(g, A) \). Hence \( |E(g, A) : E^+(g, A)| = 2 \).

\[ 7.4. \text{ Forcing a geometric separation} \]

In this subsection, we build large powers of our constricting element \( (g, A) \) to produce a translate \( Y' \) of a subset \( Y \) so that the distance between their projections to a preferred \( G \)-translate of \( A \) is large. We will do it in two different ways. We will apply these results to verify (BS4) in the construction of buffering sequences. Our main tool will be:

**Lemma 7.6.** — *There exists \( \theta \geq 0 \) such that for every \( x, x' \in X \) and for every \( m \in \mathbb{Z} \),*

\[ d_A(x, g^m x') \geq |m| |g|^\infty - d_A(x, x') - \theta. \]

**Proof.** — Let \( \theta = \theta(\delta) \geq 0 \) be the constant of Proposition 2.5. Let \( x, x' \in X \). Let \( m \in \mathbb{Z} \). If \( m = 0 \), then there is nothing to do. Assume that \( m \neq 0 \). By the triangle inequality,

\[ d_A(x, g^m x') \geq d(\pi_A(x), g^m \pi_A(x)) - d_A(x, x') - d(g^m \pi_A(x'), \pi_A(g^m x')). \]
Note that
\[
\frac{1}{|m|} d(\pi_A(x), g^m \pi_A(x)) \geq \inf_{n \geq 1} \frac{1}{n} d(\pi_A(x), g^n \pi_A(x)) = [g]^{\infty}.
\]
By Proposition 2.5 (2) Coarse equivariance, we have \(d(g^m \pi_A(x'), \pi_A(g^m x')) \leq \theta\). Therefore, we have \(d_A(x, g^m x') \geq |m||g|^{\infty} - d_A(x, x') - \theta\). □

The first way of forcing a geometric separation will be applied to the study of the relative exponential growth rates:

**Proposition 7.7.** — For every \(\varepsilon \geq 0\), \(\theta \geq 0\), there exists \(M \in \mathbb{N}_+\) with the following property. Let \(H \leq G\) be a subgroup. Let \(Y \subseteq X\) be an \(H\)-invariant subset. If \(\text{diam}_A(Y) \leq \varepsilon\), then for every \(u \in \langle g^M, H \cap E(g, A) \rangle - H \cap E(g, A)\), we have \(d_A(Y, uY) > \theta\).

**Proof.** — Let \(\varepsilon \geq 0\), \(\theta \geq 0\). Let \(\theta_0 \geq 0\) be the constant of Proposition 2.5. By Lemma 7.6, there exists \(\theta_1 \geq 0\) such that for every \(x, x' \in X\) and for every \(m \in \mathbb{Z}\),
\[
d_A(x, g^m x') \geq |m||g|^{\infty} - d_A(x, x') - \theta_1.
\]
Combining Lemma 6.10 and Proposition 2.5 (6) Morseness, we obtain \([g]^{\infty} > 0\). According to Corollary 7.5, there exists \(M_0 \in \mathbb{N}_+\) such that
\[
E(g, A) = \left\{ u \in G : \exists p \in \{-1, +1\} u g^{M_0} u^{-1} = g^{pM_0} \right\}.
\]
Let \(m_0 \geq \theta_2^{-2} - 2\theta_{0} - \theta_1\). We put \(M = M_0 m_0\).

Let \(H \leq G\) be a subgroup. Let \(Y \subseteq X\) be an \(H\)-invariant subset. Assume that \(\text{diam}_A(Y) \leq \varepsilon\). Let \(u \in \langle g^M, H \cap E(g, A) \rangle - H \cap E(g, A)\) and \(y, y' \in Y\). It follows from Corollary 7.5 that there exists \(n \in \mathbb{Z}\) multiple of \(M\) and \(f \in H \cap E(g, A)\) such that \(u = g^n f\). By the triangle inequality,
\[
d_A(y, g^n fy') \geq d_A(y, g^ny') - d(\pi_A(g^ny'), g^n \pi_A(y')) - d_A(y', fy') - d(g^n \pi_A(fy'), \pi_A(g^n fy')).
\]
By Lemma 7.6,
\[
d_A(y, g^ny') \geq |n||g|^{\infty} - d_A(y, y') - \theta_1
\]
Note that \(u \not\in H \cap E(g, A)\) implies \(n \neq 0\). Hence \(|n| \geq |M|\). Since \(f \in H\) and \(\text{diam}_A(Y) \leq \varepsilon\),
\[
\max \{d_A(y, y'), d_A(y', fy')\} \leq \varepsilon.
\]
By Proposition 2.5 (2) Coarse equivariance,
\[
\max \{d(\pi_A(g^ny'), g^n \pi_A(y')), d(g^n \pi_A(fy'), \pi_A(g^n fy'))\} \leq \theta_0.
\]
Since the elements \(y, y'\) are arbitrary, we obtain \(d_A(Y, uY) > \theta\). □
The second way of forcing a geometric separation will be applied to the study of the quotient exponential growth rates:

**Proposition 7.8.** — For every \( \epsilon > 0, \theta > 0 \), there exist \( M \in \mathbb{N}_+ \) and \( f : G \times X \to \{ 1_G, g^M \} \) with the following property. Let \( Y \subseteq X \) be subset. If \( \text{diam}_A(Y) \leq \epsilon \), then for every \( u \in G \) and for every \( y \in Y \), we have \( d_{uA}(y,uf(u,y)Y) > \theta \).

**Proof.** — Let \( \epsilon > 0, \theta > 0 \). Let \( \theta_0 > 0 \) be the constant of Proposition 7.1. By Lemma 7.6, there exists \( \theta_1 > 0 \) such that for every \( x, x' \in X \) and for every \( m \in \mathbb{Z} \),

\[
d_A(x,g^m x') \geq |m||g|^\infty - d_A(x,x') - \theta_1.
\]

Combining Lemma 6.10 and Proposition 2.5 (6) Morseness, we obtain \( |g|^\infty > 0 \). We put \( M > \frac{2\theta + 2\theta_1 + \theta_0}{|g|^\infty} \). Then, for every \( u \in G \) and for every \( x \in X \), there exists \( f(u,x) \in \{ 1_G, g^M \} \) such that \( d_A(u^{-1}x,f(u,x)x) > \theta + \epsilon + 4\theta_0 \) if \( d_A(u^{-1}x,x) > \theta + \epsilon + 4\theta_0 \), we choose \( f(u,x) = 1_G \), otherwise we choose \( f(u,x) = g^M \). This defines \( f : G \times X \to \{ 1_G, g^M \} \).

Let \( Y \subseteq X \) be subset. Assume that \( \text{diam}_A(Y) \leq \epsilon \). Let \( u \in G \). Let \( y, y' \in Y \). By abuse of notation, we write \( f \) instead of \( f(u,y) \). By the triangle inequality,

\[
d_{uA}(y,ufy') \geq d_{uA}(y,ufy) - d_{uA}(ufy,ufy').
\]

\[
d_{uA}(y,ufy) \geq d_A(u^{-1}y, fy) - d(\pi_{uA}(y), u\pi_A(ufy)) - d(\pi_{uA}(ufy), u\pi_A(ufy)),
\]

\[
d_{uA}(ufy,ufy') \leq d(\pi_{uA}(ufy), u\pi_A(ufy)) = d_A(y,y') + d(uf\pi_A(y'), \pi_{uA}(ufy')).
\]

By hypothesis, \( d_A(u^{-1}y, fy) > \theta + \epsilon + 4\theta_0 \) and \( d_A(y,y') \leq \text{diam}_A(Y) \leq \epsilon \). By Proposition 7.1,

\[
\max \{ d(\pi_{uA}(y), u\pi_A(u^{-1}y)), d(\pi_{uA}(ufy), u\pi_A(ufy)) \} \leq \theta_0.
\]

\[
\max \{ d(\pi_{uA}(ufy), u\pi_A(ufy)), d(uf\pi_A(y'), \pi_{uA}(ufy')) \} \leq \theta_0.
\]

Since the element \( y' \) is arbitrary, we obtain \( d_{uA}(y,ufY) > \theta \). \( \square \)

### 8. The growth of quasi-convex subgroups

In this section, our first goal is to prove Theorem 1.8. This result can be deduced from Proposition 3.1 and Proposition 8.1 below. Our second goal is to prove Theorem 1.11. This result can be deduced from Proposition 3.5 and Proposition 8.3 below.

We fix constants \( \mu \geq 1, \nu \geq 0, \delta \geq 0, \eta \geq 0 \) and a \( (\mu, \nu) \)-path system group \( (G,X,\Gamma) \). Throughout this section, we assume that \( G \) contains a \( \delta \)-constricting element \((g_0, A_0)\). We are going to replace the axis \( A_0 \) for \( A'_0 = E(g_0, A_0)A_0 \). As a consequence of Proposition 7.4 (II), we have \( d_{\text{Haus}}(A_0, A'_0) < \infty \). Up to replacing \( \delta \) for a larger constant, it follows from Proposition 2.5 (7) Coarse invariance and Corollary 7.5 that the element \((g_0, A'_0)\) is \( \delta \)-constricting. By abuse of notation, we still denote \( A_0 = A'_0 \). In this new setting, for every \( k \in E(g_0, A_0) \), we have \( kA_0 = \)
There exists $M$. Hence the proposition proves Theorem 1.9. Since there exist $u \in G$ such that $\text{diam}_{uA_0}(Y) \leq \theta_0$. We denote $(g, A) = (ug_0u^{-1}, uA_0)$.

**Proposition 8.1 (Theorem 1.9).** — There exist $M \in \mathbb{N}_+$ such that the natural morphism $H \ast_{H \cap E(g, A)} \langle g^M, H \cap E(g, A) \rangle \to G$ is injective.

**Remark 8.2.** — It follows from Proposition 5.1 and Proposition 7.4 that the subgroup $H \cap E(g, A)$ is finite. By Proposition 7.4, the subgroup $E(g, A)$ is a finite extension of $\langle g \rangle$. Hence the proposition proves Theorem 1.9. Since $g$ has infinite order, the finite subgroup $H \cap E(g, A)$ is a proper subgroup of $\langle g^M, H \cap E(g, A) \rangle$. Hence we can apply Proposition 3.1 to deduce Theorem 1.8.

**Proof.** — Let $\theta_1 = \theta_1(\delta) \geq 0$ be the constant of Proposition 7.1. Let $\varepsilon = \max \{\theta_0 + 2\theta_1, d(A, Y)\}$. Let $L = L(\delta, \varepsilon, 0) \geq 0$ be the constant of Corollary 4.3. By Proposition 7.7, there exists $M \in \mathbb{N}_+$ such that for every $u \in \langle g^M, H \cap E(g, A) \rangle - H \cap E(g, A)$, we have $d_A(Y, uY) > L - 2\theta_1$.

Let $\phi : H \ast_{H \cap E(g, A)} \langle g^M, H \cap E(g, A) \rangle \to G$ be the natural morphism. Let $w \in H \ast_{H \cap E(g, A)} \langle g^M, H \cap E(g, A) \rangle$ such that $w \neq 1$. We are going to prove that $\phi(w) \neq 1$. Note that the morphisms $\phi|_H$ and $\phi|_{\langle g^M, H \cap E(g, A) \rangle}$ are injective. If $w \in H \cup \langle g^M, H \cap E(g, A) \rangle$, then $\phi(w) \neq 1$.

Assume that $w \notin H \cup \langle g^M, H \cap E(g, A) \rangle$. Note that if there exists a conjugate $w'$ of $w$ such that $\phi(w') \neq 1$, then $\phi(w) \neq 1$. Up to replacing $w$ by a cyclic conjugate, there exist $n \in \mathbb{N}_+$ and a sequence $h_1, k_1, \cdots, h_n, k_n \in G$ such that $w = h_1k_1 \cdots h_nk_n$ and such that for every $i \in \{1, \cdots, n\}$ we have $h_i \in H - H \cap E(g, A)$ and $k_i \in \langle g^M, H \cap E(g, A) \rangle - H \cap E(g, A)$. For every $i \in \{1, \cdots, n\}$, we denote $u_i = h_1k_1 \cdots h_{i-1}$ and $v_i = h_1k_1 \cdots h_{i-1}h_i$. We also denote $v_0 = 1_G$.

We are going to prove that the sequence $v_0Y_0, u_1A, v_1Y, \cdots, u_nA, v_nY$ is $(\delta, \varepsilon, L)$-buffering on $\{uA\}$ and then apply Corollary 4.3. Let $i \in \{1, \cdots, n\}$. Let us prove (BS1). Assume for a moment that $i 
eq n$. Since we had modified the axis $A_0$ above, for every $j \in \{1, \cdots, n\}$, we have $k_jA = A$. Hence

$$
\pi_{u_iA}(u_{i+1}A) = \pi_{v_iA}(u_{i+1}A),
\pi_{u_{i+1}A}(u_iA) = \pi_{u_{i+1}A}(v_iA).
$$

By Proposition 7.1,

$$
diam_{u_iA}(u_{i+1}A) \leq diam(v_i\pi_A(h_iA)) + \theta_1,
\text{diam}_{u_{i+1}A}(v_iA) \leq diam(u_{i+1}\pi_A(h_i^{-1}A)) + \theta_1,
\text{diam}_A(h_i^{-1}A) \leq \text{diam}_{h_iA}(A) + \theta_1.
$$

By Proposition 7.4 (I) and (II), for every $u \notin E(g, A)$, we have $\max \{\text{diam}_A(uA), \text{diam}_{uA}(A)\} \leq$
\(\theta_0\). Consequently,

\[
\max \{ \text{diam}_{u,A}(u_{i+1}A), \text{diam}_{u_{i+1},A}(u_iA) \} \leq \theta_0 + 2\theta_1 \leq \varepsilon.
\]

Let us prove (BS2). Note that,

\[
\pi_{u_i,A}(v_{i-1}Y) = \pi_{u_i,A}(u_iY),
\pi_{u_i,A}(v_iY) = \pi_{v_i,A}(v_iY).
\]

By Proposition 7.1,

\[
\text{diam}_{u_i,A}(u_iY) \leq \text{diam}(u_i\pi_A(Y)) + \theta_1,
\text{diam}_{v_i,A}(v_iY) \leq \text{diam}(v_i\pi_A(Y)) + \theta_1.
\]

Since \(\text{diam}_A(Y) \leq \theta_0\), we obtain

\[
\max \{ \text{diam}_{u_i,A}(v_{i-1}Y), \text{diam}_{u_i,A}(v_iY) \} \leq \theta_0 + \theta_1 \leq \varepsilon.
\]

Let us prove (BS3). We have,

\[
\max \{ d(u_iA, v_{i-1}Y), d(u_iA, v_iY) \} = \max \{ d(u_iA, u_iY), d(v_iA, v_iY) \} \leq d(A, Y) \leq \varepsilon.
\]

Let us prove (BS4). It follows from Proposition 7.1 (I) that,

\[
d_{u_i,A}(v_{i-1}Y, v_iY) \geq d_A(Y, k_iY) - 2\theta_1.
\]

By the choice of \(M\), we have \(d_A(Y, k_iY) > L + 2\theta_1\). Hence, we have \(d_{u_i,A}(v_{i-1}Y, v_iY) \geq L\). This proves that the sequence \(v_0Y, u_1A, v_1Y, \ldots, u_nA, v_nY\) is \((\delta, \varepsilon, L)\)-buffering on \(\{u_iA\}\). It follows from Corollary 4.3 that \(d_{u_{n-1},A}(Y, \phi(w)Y) > 0\). Hence, \(\phi(w) \neq 1\).

\[\Box\]

Recall that given \(\phi: G \to G\), we say that \(G\) is \(\phi\)-coarsely \(G/H\) if there exist \(\theta \geq 0, x \in X\) satisfying the following conditions:

\[(CQ1)\text{ For every } u, v \in G, \text{ if } \phi(u)H = \phi(v)H, \text{ then } d(\phi(u)x, \phi(v)x) \leq \theta.\]

\[(CQ2)\text{ For every } u \in G, d(ux, \phi(u)x) \leq \theta.\]

**Proposition 8.3.** — There exist \(M \in \mathbb{N}_+\) and a map \(f: G \to \{1_G, g^M\}\) with the following property. Let \(\phi: G \to G, u \mapsto uf_u\). Then \(G\) is \(\phi\)-coarsely \(G/H\).

We prove some preliminar lemmas.

**Lemma 8.4.** — There exists \(\theta \geq 0\) such that for every \(m \in \mathbb{Z}\), we have \(\text{diam}_A(g^mY) \leq \theta\).
Proof. — Let \( \theta_1 \geq 0 \) be the constant of Proposition 2.5. We put \( \theta = \theta_0 + 2\theta_1 \). Let \( m \in \mathbb{Z} \).

Let \( x, x' \in Y \). By the triangle inequality,

\[
d_A{(g^m x, g^m x')} \leq d(\pi_A(g^m x), g^m \pi_A(x)) + d_A(x, x') + d(g^m \pi_A(x'), \pi_A(g^m x')).
\]

By Proposition 2.5 (2) Coarse equivariance,

\[
\max \{d(\pi_A(g^m x), g^m \pi_A(x)), d(g^m \pi_A(x'), \pi_A(g^m x'))\} \leq \theta_1.
\]

Moreover, we have \( d_A(x, x') \leq \text{diam}_A(Y) \leq \theta_0 \). Since \( x, x' \) are arbitrary, we obtain \( \text{diam}_A(g^m Y) \leq \theta_0 + 2\theta_1 \).

**Lemma 8.5.** — For every \( \varepsilon \geq 0 \), there exists \( \theta \geq 0 \) with the following property. Let \( A_1, A_2 \subseteq X \) be \( \delta \)-constricting subsets such that \( d_{\text{Haus}}(A_1, A_2) \leq \varepsilon \). Let \( x \in A_1^{+\varepsilon} \) and \( y \in A_2^{-\varepsilon} \) such that \( d_A(x, y) \leq \varepsilon \). Then \( d(x, y) \leq \theta \).

**Proof.** — Let \( \theta_1 \geq 0 \) be the constant of Proposition 2.5. Let \( \varepsilon \geq 0 \). Let \( \theta \geq 0 \). Its exact value will be precised below. Let \( A_1, A_2 \subseteq X \) be \( \delta \)-constricting subsets such that \( d_{\text{Haus}}(A_1, A_2) \leq \varepsilon \).

Let \( x \in A_1^{+\varepsilon} \) and \( y \in A_2^{-\varepsilon} \) such that \( d_A(x, y) \leq \varepsilon \). By the triangle inequality,

\[
d(x, y) \leq d(x, \pi_A(x)) + d_A(x, y) + d(\pi_A(y), y).
\]

Since \( x, y \in A_1^{+2\varepsilon+1} \), it follows from Proposition 2.5 (1) Coarse nearest-point projection that

\[
\max \{d(x, \pi_A(x)), d(\pi_A(y), y)\} \leq \mu (2\varepsilon + 1) + \theta_1.
\]

Finally, we put \( \theta = \varepsilon + 2\mu (2\varepsilon + 1) + 2\theta_1 \).

We are ready to prove Proposition 8.3:

**Proof of Proposition 8.3.** — Let \( \theta_1 \geq 0 \) be the constant of Proposition 7.1. Let \( \theta_2 \geq 0 \) be the constant of Proposition 7.4. Let \( \theta_3 \geq 0 \) be the constant of Lemma 8.4. Let \( \varepsilon = \max \{\theta_2 + 2\theta_1, \theta_1 + \theta_3, d(A, Y) + 1\} \). In particular, there exists \( y \in A^{+\varepsilon} \cap Y \). Let \( \theta_4 = \theta_4(\delta, \varepsilon) \geq 0 \) be the constant of Proposition 4.2. By Proposition 7.8, there exist \( M \in \mathbb{N}_+ \) and \( f: G \rightarrow \{1_G, g^M\} \) such that for every \( u \in G \), we have \( d_u A(y, uf(u) Y) > \theta_4 \). For every \( u \in G \), we denote \( f_u = f(u) \) and we put \( \phi: G \rightarrow G, u \mapsto uf_u \). Let \( \theta_5 = \theta_5(\varepsilon) \geq 0 \) be the constant of Lemma 8.5. We put \( \theta = \max \{d(y, g^M y), \theta_5\} \). We are going to prove that \( G \) is \( \phi \)-coarsely \( G/H \) with respect to \( y \) and \( \theta \).

In order to prove (CQ1), we just need to observe that for every \( u \in G \), we have

\[
d(u y, uf_u y) = d(y, f_u y) \leq d(y, g^M y) \leq \theta.
\]

Let us prove (CQ2). Let \( u, v \in G \). Assume that \( uf_u H = vf_v H \). We claim that \( d_{\text{Haus}}(u A, v A) \leq \theta_2 \). By Proposition 7.4 (I), it suffices to prove that \( \max \{\text{diam}_{v^{-1} u A}(A), \text{diam}_{A}(v^{-1} u A)\} > \theta_2 \).
We argue by contradiction. Assume instead that \( \max \{ \text{diam}_{v^{-1}uA}(A), \text{diam}_A(v^{-1}uA) \} \leq \theta_2 \). We are going to prove that the sequence \( uA, uf_YvA \) is \((\delta, \varepsilon, 0)\)-buffering on \( \{uA, vA\} \) and then apply Proposition 4.2. Note that the condition (BS4) is void in this case. Let us prove (BS1). By Proposition 7.1,
\[
\text{diam}_{uA}(vA) \leq \text{diam}(u\pi_A(u^{-1}vA)) + \theta_1,
\]
\[
\text{diam}_{vA}(uA) \leq \text{diam}(v\pi_A(v^{-1}uA)) + \theta_1,
\]
\[
\text{diam}_A(u^{-1}vA) \leq \text{diam}_{v^{-1}uA}(A) + \theta_1.
\]
Hence,
\[
\max \{ \text{diam}_{uA}(vA), \text{diam}_{vA}(uA) \} \leq \theta_2 + 2\theta_1 \leq \varepsilon.
\]
Let us prove (BS2). By Proposition 7.1,
\[
\text{diam}_{uA}(uf_Y) \leq \text{diam}(u\pi_A(f_Y)) + \theta_1,
\]
\[
\text{diam}_{vA}(vf_Y) \leq \text{diam}(v\pi_A(f_Y)) + \theta_1.
\]
By Lemma 8.4, we have \( \max \{ \text{diam}_A(f_Y), \text{diam}_A(f_Y) \} \leq \theta_3 \). Hence,
\[
\max \{ \text{diam}_{uA}(uf_Y), \text{diam}_{vA}(vf_Y) \} \leq \theta_1 + \theta_3 \leq \varepsilon.
\]
Let us prove (BS3). The hypothesis \( uf_uH = vf_vH \) implies \( uf_uY = vf_vY \) and therefore
\[
\max \{ d(uA, uf_uY), d(vA, uf_uY) \} = \max \{ d(uA, uf_uY), d(vA, vf_vY) \} = d(A, Y) \leq \varepsilon.
\]
Hence, the sequence \( uA, uf_uY, vA \) is \((\delta, \varepsilon, 0)\)-buffering on \( \{uA, vA\} \). It follows from Proposition 4.2 that
\[
\min \{ d_{uA}(y, uf_uY), d_{vA}(y, uf_uY) \} \leq \theta_4.
\]
However, by construction,
\[
\min \{ d_{uA}(y, uf_uY), d_{vA}(y, uf_uY) \} > \theta_4.
\]
Contradiction. Therefore, \( \text{dHaus}(uA, vA) \leq \theta_2 \). This proves the claim. In particular, \( \text{dHaus}(uA, vA) \leq \varepsilon \). Since \( y \in A^{+\varepsilon} \), we have \( uf_uy \in uA^{+\varepsilon} \) and \( vf_vy \in vA^{+\varepsilon} \). Since \( uf_uy, vf_vy \in uf_uY \), we have \( d_{uA}(uf_uy, vf_vy) \leq \text{diam}_{uA}(uf_uY) \leq \varepsilon \). According to Lemma 8.5, \( d(uf_uy, vf_vy) \leq \theta \). This proves (CQ2).
