The two studies together had the participation of more than 1,400 patients, who were randomly distributed to receive one or another treatment. They had a viral load of less than 500,000 copies, although there was 2% of participants in each arm with more than 500,000 copies. Stratified results were presented according to viral load and CD4 levels. The main objective of both studies was to establish the percentage of participants with a viral load below 50 copies/ml at 48 weeks after starting the study.

The results showed a virologic efficacy generally consistent across subgroups stratified by baseline HIV-1 RNA. Efficacy of DTG plus 3TC was numerically lower in patients with low baseline CD4+ cell count in Snapshot analysis, but not in treatment-related discontinuation equals failure (TRDF) analysis. The numerical difference is evident in the subset of patients with lower baseline CD4+ cell counts who received dual therapy. Here, 79% of patients receiving dual therapy achieved virologic success compared with 93% of those receiving triple therapy. However, only 1 of these 13 dual therapy recipients without HIV-1 RNA < 50 copies/mL at Week 48 was a true virologic failure. It is also important consider that the percentage of patients with CD4<200 was only 9%.

On the other hand, low rates of confirmed virologic withdrawal through Week 48 (< 1% of patients per arm) were observed. No treatment-emergent INSTI mutations or NRTI mutations were seen among participants who met CVW (confirmed virologic failure) criteria.

Finally, the safety findings were comparable between arms and were observed significant differences in impact on renal and bone biomarkers in favour of DTG plus 3TC arm.

In conclusion, a dual therapy with 3TC + DTG in naive patients could be an alternative to a triple therapy based on TDF + FTC + DTG. Since the life expectancies in patients with HIV are extended, it is important to consider use of therapies that reduce cumulative drug exposure and toxicity.
Risk of HIV transmission through condomless sex in gay couples with suppressive ART: The PARTNER2 study extended results in gay men

This prospective, observational, multicenter study assessed HIV transmission risk in serodifferent men who have sex with men (MSM) couples reporting condomless sex when HIV-positive partner virologically suppressed [4-6]. PARTNER2 followed MSM from 2014-2018 (included some MSM couples from PARTNER1). Ninety seventy-two couples MSM were recruited, of whom 783 contributed 1.596 eligible couple-years of follow up (CYFU). The main finding of the study was that no within-couple HIV trans - missions were observed among 783 serodifferent MSM couples who reported condomless (CL) sex while the HIV-positive partner was receiving suppressive ART. Nevertheless, 15 HIV-negative men acquired HIV infection during follow-up, although none of these infections was phylogenetically linked to the HIV-positive partner. During almost 77,000 within-couple CL sex acts, upper 95% CI for rate of transmission between MSM was 0.23/100 CYFU. This data shows, with more statistical certainty than in the PARTNER1 study, that the risk of HIV transmission from an HIV-positive partner who has undetectable HIV-1 RNA is effectively zero.

Incidence of HIV-Infection in the AVRS Prevenir Study in the Paris Region with daily or On Demand PrEP with TDF/FTC

Molina et al. [7] showed the real-life data of the PrEP (pre-exposure prophylaxis) application in Paris. PREVENIR is a multicenter, open-label, prospective cohort study in Paris that includes HIV-negative adults at high risk of HIV infection with inconsistent condom use. At the beginning of the study, participants choose between daily or on demand prophylaxis, being able to change their arm during the course of the same. A total of 1,594 participants were enrolled, 98% MSM. The primary endpoint was a ≥ 15% reduction in new HIV diagnoses among MSM in Paris vs rate reported by National Surveillance network in 2016. Secondary endpoints were to analyse PrEP adherence, sexual behaviour, and safety. At an average follow-up of 7 months, the incidence of HIV in both groups

Darunavir/Cobicistat/Etricitabine/Tenofovir Alafenamide (D/C/F/TAF) in a Test-and-Treat Model of Care for HIV-1 Infection: Interim Analysis of the DIAMOND Study

Many studies have shown the benefits of the immediate initiation of antiretroviral treatment (without waiting the results of the resistance study or the viral load and CD4 data) in patients newly diagnosed with HIV infection, especially in populations with low resources and difficult access to the health system. Benefits in retention of care, morbidity, mortality and time in obtaining virological suppression has been described.

DIAMOND [3] is an ongoing phase 3, single arm, open label, prospective multicenter study evaluating D/C/F/ TAF in a rapid initiation model of care over 48 weeks. The main objectives of the study are: a) to assess the efficacy and safety of this regimen in the treatment of newly diagnosed HIV 1 infected naïve patients; b) to assess the baseline viral resistance in the study population; and c) to evaluate the results of an HIV Treatment Satisfaction Questionnaire status version (HIVTSQs) at weeks 4 and 24. This is the first phase 3 trial of an STR in a rapid initiation model of care.

In this trial, a high proportion of patients using D/C/F/ TAF achieved HIV-1 RNA <50 copies/ml, and 91% (99/109) of patients continued treatment through the interim analysis at week 24. It is a remarkable finding that no patients discontinued treatment due to receipt of baseline resistance reports, and no patients had confirmed virologic failure or discontinued due to lack of efficacy. On the other hand, at weeks 4 and 24, the results of the mean HIVTSQs score approached the maximum of 60, indicating a high level of satisfaction. These findings together with the efficacy, high barrier to resistance, safety profile and convenience of a single table regimen, suggest that D/C/F/ TAF should be considered an adequate option of treatment in a quick initiation model of care.
was 0, and it was estimated that 85 HIV infections had been prevented. Regarding safety, 11 participants were diagnosed of viral hepatitis, including 7 cases of hepatitis C. Among the groups, the incidence of the first viral hepatitis was 1.1/100 patient-years for daily PrEP and 1.2/100 patients-year for PrEP on demand. In the adherence analysis, it was observed a high rate of correct PrEP use in daily and on-demand groups, being both of 96%. In terms of sexual behaviour, daily PrEP users reported higher numbers of condomless sex acts, and sexual partners at baseline.
