HEIGHT FUNCTIONS ON HECKE ORBITS AND THE GENERALISED ANDRÉ-PINK-ZANNIER CONJECTURE

RODOLPHE RICHARD AND ANDREI YAFAEV.

Abstract. We introduce and study the notion of a generalised Hecke orbit in a Shimura variety. We define a height function on such an orbit and study its properties. We obtain lower bounds for the sizes of Galois orbits of points in a generalised Hecke orbit in terms of this height function, assuming the “weakly adelic Mumford-Tate hypothesis” and prove the generalised André-Pink-Zannier conjecture under this assumption, using Pila-Zannier strategy.

1. Introduction

In this paper, we study the generalised André-Pink-Zannier conjecture for all Shimura varieties, whose statement is as follows.

2010 Mathematics Subject Classification. 03C64, 11G18, 11G50, 11F80, 14L30, 20G35, 15A16, 14G35.

Key words and phrases. Shimura varieties, Hecke orbits, Zilber-Pink, Heights, Siegel sets, Mumford-Tate conjecture, Adelic linear groups.
Conjecture 1.1 (Generalised André-Pink-Zannier). Let $S$ be a Shimura variety and $\Sigma$ a subset of a generalised Hecke orbit in $S$. Then the irreducible components of the Zariski closure of $\Sigma$ are weakly special subvarieties.

We refer to [12, 13] for notions and notations concerning Shimura data and Shimura varieties. We refer to [52, §3] for definitions and properties of weakly special subvarieties. We refer to Def. 2.1 or §1.1 below for the notion of generalised Hecke orbits.

1.1. Main result. Let $(G, X)$ be a Shimura datum, and $K \leq G(\mathbb{A}_f)$ be a compact open subgroup, and $S = Sh_K(G, X) = G(\mathbb{Q}) \backslash X \times G(\mathbb{A}_f)/K$ be the associated Shimura variety. Let $x_0 \in X$ and denote by $M \leq G$ its Mumford-Tate group. Let $s_0 := [x_0, 1] \in S$.

The generalised Hecke orbit of $x_0$ in $X$ (see §2.1) is the set $\mathcal{H}(x_0)$ of the $\phi \circ x_0$, where $\phi : M \to G$ ranges through the morphisms of $\mathbb{Q}$-algebraic groups such that $\phi \circ x_0 \in X$. The generalised Hecke orbit of $s_0$ in $S$ is $\mathcal{H}(s_0) := G(\mathbb{Q}) \backslash \mathcal{H}(x_0) \times G(\mathbb{A}_f)/K \subseteq S$. For a sufficiently large field $E$ of finite type over $\mathbb{Q}$ we have the following (see §3.1): $S$ and $s_0$ are defined over $E$ and there exists a Galois representation $\rho_{x_0} : Gal(\overline{E}/E) \to M(\mathbb{A}_f) \cap K$ such that

$$\forall \sigma \in Gal(\overline{E}/E), \ g \in G(\mathbb{A}_f), \ \sigma([x_0, g]) = [x_0, \rho_{x_0}(\sigma) \cdot g].$$

The main result of this paper is the following.

Theorem 1.2. We consider the above situation. We assume the weakly adelic Mumford-Tate hypothesis (see §6.3), which states that, with $U := \rho_{x_0}(Gal(\overline{E}/E)) \subseteq M(\mathbb{A}_f) \cap K$:

$$\exists C > 0, \forall p, \ [K \cap M(\mathbb{Q}_p) : U \cap M(\mathbb{Q}_p)] \leq C.$$

Then, for any subset $\Sigma \subseteq \mathcal{H}(s_0)$, every irreducible component of $\overline{\Sigma}^{\text{Zar}}$ is weakly special.

Our “weakly adelic Mumford-Tate hypothesis” is weaker than the adelic form of the Mumford-Tate conjecture [49, 11.4?] stated by Serre. Here are some instances in which above Theorem 1.2 implies Conjecture 1.1 unconditionally.

Combining Th. 1.2 with Lemma 6.4, one recovers the following.

Theorem 1.3 ([15] and [24]). Conjecture 1.1 is true if $\Sigma$ contains a special point.

Combining Th. 1.2 with [8, Th. A (i)] we have the following, which strictly contains a 2005 result of Pink [35, §7] (and [7, Th. B]).
Theorem 1.4. Conjecture 1.1 is true if $S$ is of abelian type, and $\Sigma$ contains a point $s$ which satisfies the Mumford-Tate conjecture (at some $\ell$, in the sense of [53]).

The assumptions of Th. 1.4 are satisfied in the case where $S = A_g$ and $\Sigma$ contains a point $[A]$, where the abelian variety $A$ satisfies the Mumford-Tate conjecture (at some prime $\ell$). Examples of such abelian varieties are: when $\dim(A) \leq 3$; or when $\dim(A)$ is odd and $\text{End}(A) \simeq \mathbb{Z}$. More examples were given in [36], and many examples are mentioned in [28, §2.4].

The assumptions of Th. 1.4 are also satisfied for “most” points in $S(\overline{\mathbb{Q}})$ (with $S$ of abelian type) in the following sense. The subset consisting of the $s \in S(\overline{\mathbb{Q}})$ such that $s$ does not satisfy the Mumford-Tate conjecture is thin in the sense of [47, §9.1]: this uses a combination of [48, §1], [47, §9] and [8, Th. A (i)] and Th. 6.16.

For arbitrary Shimura varieties, the hypotheses of Th. 1.2 are satisfied in the situation of Th. 6.16. In a sense, our results apply unconditionally to “most” nonalgebraic points of a Shimura variety. The following are two special cases of Th. 6.16.

Theorem 1.5. Conjecture 1.1 is true if $\Sigma$ contains a $\overline{\mathbb{Q}}$-Zariski generic point $s$ of a special subvariety $Z \subseteq S$, namely: for every proper subvariety $V \subsetneq Z$ defined over $\overline{\mathbb{Q}}$, we have $s \not\in V(\mathbb{C})$.

Theorem 1.6. Conjecture 1.1 is true if $M^{\text{ad}}$ is $\mathbb{Q}$-simple and $\Sigma$ contains a point $s$ in $S(\mathbb{C}) \setminus S(\overline{\mathbb{Q}})$.

1.2. History of Conjecture 1.1. Conjecture 1.1 is a special case of the Zilber-Pink conjecture, which has been and continues to be a subject of active research.

Conjecture 1.1 was first formulated (in a special case) in 1989 by Y. André in [1, Ch. X, §4.5] (Problem 3). U. Zannier has considered questions of this type in the context of abelian schemes and tori in [56]. It was then stated in the introduction to the second author’s 2000 PhD thesis [55, bottom of p. 12]², following discussions with Bas Edixhoven. Richard Pink, in his 2005 paper [35], has formulated and studied this question.

These authors consider the classical Hecke³ orbit as in Def. 2.14.

---

¹We refer to [33], proof of Lemma 2.2, for the argument, which applies to our generalised setting.

²The statement there uses the terminology ‘totally geodesic subvarieties’ instead of ‘weakly special’, but Moonen had proved in [31] that the two notions are equivalent.

³Where André uses $G(\mathbb{Q})$, Pink uses $\text{Aut}(G)(\mathbb{Q})$ instead of $G(\mathbb{Q})$ in Def. 2.14.
Pink proves the André-Pink-Zannier conjecture for “Galois generic” points of $\mathcal{A}_g$. These points are Hodge generic, by [7, Pr. 6.2.1]. Pink’s method uses equidistribution of Hecke points (by Clozel-Oh-Ullmo: [10]; cf. also [17]). This was generalised to Galois generic points in arbitrary Shimura varieties in 2016’s [7]. This was also contained in the 2009’s first author’s thesis under a weaker assumption [39, Ch. III §7, p. 59, Cor. 7.1].

In the case of generalised Hecke orbits of special points, the articles [15, 24] use a method of Edixhoven. This method is inapplicable in more general cases, for instance the case of the Hecke orbit of a Hodge generic point.

A real breakthrough on this problem was the introduction of the Pila-Zannier strategy which uses o-minimality and functional transcendence. It has now become the most powerful approach to all problems of Zilber-Pink type. This method was applied by M. Orr in [33], who considered the case of curves in $\mathcal{A}_g$, the moduli space of principally polarised abelian varieties. His approach relies on Masser-Wüstholz isogeny estimates. Therefore, it is limited to Shimura varieties of abelian type, and can’t be applied to generalised Hecke orbits. For Shimura varieties of abelian type, Orr was able to prove the conjecture for ",S-adic Hecke orbits"5 for a finite set of primes $S$, and for points which are Hodge generic (without the Galois generic assumption).

In the case of $S$-adic Hecke orbits, a stronger form of the conjecture, involving topological closure and equidistribution, was proved, in the abelian case, in [41] using ergodic theory approach relying on $p$-adic Ratner’s theorems.

1.3. Main technical results. After choosing bases of the Lie algebras $\mathfrak{m}$ of $M$ and $\mathfrak{g}$ of $G$, we associate to $\phi \in \text{Hom}(M,G)$ its "finite height" $H_f(\phi)$, defined as the lowest common multiple of the denominators of the coefficients of the matrix of $d\phi$. More generally, for $g \in G(\mathbb{A}_f)$, we define $H_f(g^{-1} \cdot \phi \cdot g)$ as the smallest $n \in \mathbb{Z}_{\geq 1}$ such that the matrix of $g^{-1} \cdot \phi \cdot g$ has coefficients in $\hat{\mathbb{Z}}$.

---

4They used a generalised notion of Hecke orbit, formulated using auxiliary linear representations; but using Prop. 2.15 and Th. 2.4, this leads to a statement equivalent to our Conj. 1.1.

5He considers Hecke correspondences whose level has only prime factors in $S$. This corresponds to isogenies of abelian varieties whose degree has prime factors only from $S$. 
1.3.1. A first crucial result is the following. We choose the bases of $g$ and $m$ constructed in §4.3. Then the function

$$[\phi \circ x_0, g] \mapsto H_f(g^{-1} \cdot \phi \cdot g)$$

is well defined on the generalised Hecke orbit, and $Gal(\overline{E}/E)$-invariant.

1.3.2. Our most important technical result is an estimate on the size of Galois orbits in a generalised Hecke orbit.

The following definition is used throughout this article.

**Definition 1.7.** Let $A$ be a set and $f, g : A \to \mathbb{R}_{\geq 0}$ two functions.

1. We say that $f$ polynomially dominates $g$, and write $g \preceq f$, if there exist $a, b, c \in \mathbb{R}_{>0}$ such that

$$\forall x \in A, g(x) \leq c + af(x)^b.$$  

2. We say that $f$ and $g$ are polynomially equivalent, and write $f \approx g$, if $f \preceq g$ and $g \preceq f$.

As functions on the generalised Hecke orbit $\mathcal{H}(s_0)$, we have the polynomial equivalence

$$\#Gal(\overline{E}/E) \cdot [\phi \circ x_0, g] \approx H_f(g^{-1} \cdot \phi \cdot g).$$

1.3.3. Another essential technical result, from §5, is the following. See the introduction in §5 for the importance of this result in our approach to Conjecture 1.1.

Denote by $\phi_0$ the inclusion monomorphism $M \hookrightarrow G$. Let $W$ be the conjugacy class $G \cdot \phi_0 \subseteq \text{Hom}(M, G)$, viewed as an algebraic variety over $\mathbb{Q}$. The usual height of the matrix of $d\phi$ defines an affine Weil height function $H_W$ on $W(\mathbb{Q})$ (cf. (14) and (17)). Let $\mathfrak{S} \subseteq G(\mathbb{R})$ be a finite union of Siegel sets and $\mathfrak{S} \cdot \phi_0$ be its image in $W(\mathbb{R})$.

The main result 5.16 of §5 is that, as functions of $\phi \in W(\mathbb{Q}) \cap \mathfrak{S} \cdot \phi_0$, we have

$$H_f(\phi) \approx H_W(\phi).$$

We note that every point of the geometric Hecke orbit can be written as $[\phi \circ x_0, g]$ with $g \in G(\mathbb{A}_f)$ and $\phi \in W(\mathbb{Q}) \cap \mathfrak{S} \cdot \phi_0$, provided $\mathfrak{S} \subseteq G(\mathbb{R})$ is a fundamental set.

1.4. **Outline of the strategy.** The proof of Theorem 1.2 is given in §7. The technical results of §1.3 play a crucial role in our approach. Let us outline our approach.

We reduce the Conjecture 1.1 to the case where $V := \Sigma = \{s_0; s_1; \ldots\}$ is irreducible, $G$ is adjoint and $V$ is Hodge generic in $S$. We rely on functoriality properties §2.2 of geometric and generalised Hecke orbits.\(^6\)

\(^6\)This avoids one difficulty in the approach [33] of Orr.
Theorem 2.4 allows us to use geometric and generalised Hecke orbits interchangeably. We also rely on the functoriality properties §6.3 of the assumption (1).

The final objective of the proof is to apply the geometric part of the André-Oort conjecture [52] (or [40]), and use induction on the number of simple factors of $M^{\text{ad}}$. For every $n$ large enough, we construct a weakly special subvariety $Z_n \subseteq V$ of non-zero dimension such that $s_n \in Z_n$. Then [52, 40] describes $\bigcup Z_n$, and we deduce Conjecture 1.1.

In order to construct the non-zero dimensional $Z_n$, we use the Pila-Zannier strategy. By (3), we identify $\mathcal{H}(s_0)$ with a subset of $W(Q)$ where $W = G \cdot \phi_0 \simeq G/Z_G(M)$ is the algebraic variety of §1.3.3.

Let $\pi : G(\mathbb{R}) \to X \to S$ be the uniformisation map, and $\mathfrak{S} \subseteq G(\mathbb{R})$ is a finite union of Siegel sets such that $S = \pi(\mathfrak{S})$. The goal is to apply the variant Th. 7.1 of Pila-Wilkie theorem, after constructing many rational points of small height in the set

$$\tilde{V} = \left(\pi^{-1}(V) \cap \mathfrak{S}\right)/Z_G(\mathbb{R})(M) \subseteq W(\mathbb{R})$$

which is definable in the o-minimal structure $\mathbb{R}_{\text{an}, \exp}$.

Let $E$ be field of definition of $V$. Then $V$ contains the Galois orbits $\text{Gal}(\overline{E}/E) \cdot s_n$.

We introduce

$$Q_n := \{ \phi \in \mathfrak{S} \cdot \phi_0 \cap W(Q) : [\phi \circ x_0 : 1] \in \text{Gal}(\overline{E}/E) \cdot s_n \} \subseteq \tilde{V}.$$  

Denote by $p$ the map $G(\mathbb{R}) \cdot \phi_0 \to X$, where $G(\mathbb{R}) \cdot \phi_0 \subseteq W(\mathbb{R})$. Each point $s' \in \text{Gal}(\overline{E}/E) \cdot s_n$ lifts to a rational point $s' \in \tilde{V} \cap W(Q)$. We have surjections $Q_n \to p(Q_n) \to \text{Gal}(\overline{E}/E) \cdot s_n$. Thus $\#Q_n \geq \#\text{Gal}(\overline{E}/E) \cdot s_n$.

By §1.3.1, the value of $H_\phi$ is constant as $\phi$ ranges through $Q_n$. By §1.3.3, we also have $H_\phi(\phi) \approx H_\phi(\phi)$. By §1.3.2, we have $\#Q_n \geq \#\text{Gal}(\overline{E}/E) \cdot s_n \approx H_\phi(\tilde{s}_n) \approx H_\phi(\tilde{s}_n)$.

Thus $\tilde{V}$ contains $\#Q_n \approx H_\phi(\tilde{s}_n)$ points of height $\approx H_\phi(\tilde{s}_n)$.

By Th. 7.1, for sufficiently large $n$, there exist $\phi_n \in Q_n$ such that $p(\phi_n) \in Z^{\text{alg}}$, with $Z = p(\tilde{V})$. By Ax-Lindemann-Weierstrass theorem [25], it follows that $s'_n = [\phi_n, 1] \in Z_n \subseteq V$, for a non-zero dimensional weakly special subvariety $Z_n$. Using Galois action, we may assume $s'_n = s_n$.

This concludes the proof of Th. 1.2.

1.5. In Section 2, we introduce and study generalised and geometric Hecke orbits. In Section 3, we recall properties of the representations $\rho_{x_0} : \text{Gal}(\overline{E}/E) \to M(\mathbb{A}_f)$, and we relate Galois orbits to orbits of $U = \rho_{x_0}(\text{Gal}(\overline{E}/E))$. In Section 4, we make precise and prove 1.3.1.
The Section 5 deals with 1.3.2. In Section 6, we introduce and study the weakly adelic Mumford-Tate hypothesis, and establish the estimates 1.3.3. This relies on general estimates on adelic orbits, given in the appendices. The content of Section 7 was outlined in 1.4.

Acknowledgments. The second named author has been contemplating the André-Pink-Zannier problem and how to use the Mumford-Tate conjecture to approach it for twenty years. He had a number of discussions on the subject with Bas Edixhoven, Richard Pink, Yves André, Emmanuel Ullmo, Bruno Klingler, Martin Orr, Christopher Daw,... Both authors would like to thank them all.

Both authors were supported by Leverhulme Trust Grant RPG-2019-180. The support of the Leverhulme Trust is gratefully acknowledged.

2. Generalised and Geometric Hecke orbits.

In this section we define the notions of generalised Hecke orbit and of geometric Hecke orbit, and study their properties. The heart of this section is Theorem 2.4, which in particular implies that generalised and geometric Hecke orbits can be used interchangeably in the statement of Conjecture 1.1.

These notions are naturally compatible with various operations on Shimura data. In particular we prove several statements which will be important in reducing the conjecture 1.1 to the case where the Shimura variety is of adjoint type and $\Sigma$ is Hodge generic in $S$.

Finally §2.5 compares our notions to different notions of generalised Hecke orbits found in the literature.

2.1. Let $(G, X)$ be a Shimura datum. We always assume, as in [54], that our Shimura datum is normalised so that $G$ is the generic Mumford-Tate group of $X$.

Let $x_0$ be a point of $X$ and let $M \leq G$ be the Mumford-Tate group of $x_0$. Recall that $x_0$ is a morphism $S := \text{Res}_{\mathbb{C}/\mathbb{R}}(GL(1)) \to G_{\mathbb{R}}$ and that $M = x_0(S)_{\text{Zar}, \mathbb{Q}}$ is the smallest $\mathbb{Q}$-algebraic subgroup of $G$ containing $x_0(S)$. In the rest of the paper we denote the identity monomorphism $M \hookrightarrow G$ by $\phi_0$.

In the following definition $\text{Hom}(M, G)$ denotes the set of algebraic group morphisms defined over $\mathbb{Q}$.

**Definition 2.1** (Generalised Hecke orbit). *We define the Generalised Hecke orbit $\mathcal{H}(x_0)$ of $x_0$ in $X$ as*

$$\mathcal{H}(x_0) := X \cap \{ \phi \circ x_0 : \phi \in \text{Hom}(M, G) \}.$$
Let \( X_M = M \cdot x_0 \subset X \). Then \((M, X_M)\) is a Shimura datum, and the \( \phi \in \text{Hom}(M, G) \) such that \( \phi \circ x_0 \in X \) are precisely those giving rise to a morphism of Shimura data \((M, X_M) \to (G, X)\). In particular \( \phi(X_M) \subseteq X \).

Let \( K \) be a compact open subgroup of \( G(\mathbb{A}_f) \) and \( \text{Sh}_K(G, X) \) be the Shimura variety associated to this data. There is a natural map
\[
X \times G(\mathbb{A}_f) \longrightarrow \text{Sh}_K(G, X)
\]
and we denote the image of a point \((x, g)\) by \([x, g]\).

**Definition 2.2.** We define the Generalised Hecke orbit \( \mathcal{H}([x_0, g_0]) \) of \([x_0, g_0]\) in \( \text{Sh}_K(G, X) \) by
\[
\mathcal{H}([x_0, g_0]) := \{[x, g] : x \in \mathcal{H}(x_0), g \in G(\mathbb{A}_f)\}.
\]

Let \( W = G \cdot \phi_0 \) be the conjugacy class of \( \phi_0 \) which we view as an algebraic variety defined over \( \mathbb{Q} \). Denoting by \( Z_G(M) \) the centraliser of \( M \) in \( G \), we will identify \( G/Z_G(M) \approx W \). The set \( W(\overline{\mathbb{Q}}) \) is the \( G(\overline{\mathbb{Q}}) \)-conjugacy class of \( \phi_0 \) in \( \text{Hom}(M_{\overline{\mathbb{Q}}}, G_{\overline{\mathbb{Q}}}) \), and the points in \( W(\mathbb{Q}) \) are the \( \mathbb{Q} \)-defined homomorphisms \( \phi \in \text{Hom}(M, G) \) which are conjugated to \( \phi_0 \) by elements of \( G(\overline{\mathbb{Q}}) \).

In Def. 2.1, if we replace \( \text{Hom}(M, G) \) by its subset \( W(\mathbb{Q}) \), we obtain a more restrictive definition: that of a geometric Hecke orbit.

**Definition 2.3.** We define the geometric Hecke orbit \( \mathcal{H}^g(x_0) \) of \( x_0 \) by
\[
\mathcal{H}^g(x_0) = X \cap \{\phi \circ x_0 : \phi \in W(\mathbb{Q})\} \subset \mathcal{H}(x_0)
\]
and the geometric Hecke orbit of \([x_0, g_0]\) by
\[
\mathcal{H}^g([x_0, g_0]) = \{[x, g] : x \in \mathcal{H}^g(x_0), g \in G(\mathbb{A}_f)\}.
\]

The main result of this section is the following.

**Theorem 2.4.** The generalised Hecke orbit \( \mathcal{H}(x_0) \) is a union of finitely many geometric Hecke orbits.

**Lemma 2.5.** Let \( \phi, \phi' \in \text{Hom}(M, G) \) (defined over \( \mathbb{Q} \)) be such that \( \phi \circ x_0 = \phi' \circ x_0 \).

Then \( \phi = \phi' \).

**Proof.** One can check directly that
\[
H := \{m \in M(\mathbb{C}) : \phi(m) = \phi'(m)\}
\]
is a subgroup of \( M(\mathbb{C}) \) (it is the “equaliser” of \( \phi \) and \( \phi' \)). It is algebraic and defined over \( \mathbb{Q} \) because \( \phi \) and \( \phi' \) are. It contains the image \( x_0(\mathbb{C}) \) by hypothesis. But \( M \) is the Mumford-Tate group of \( x_0 \): there is no proper \( \mathbb{Q} \)-algebraic subgroup of \( M \) containing \( x_0(\mathbb{C}) \). Therefore \( H = M \). Thus \( \phi = \phi' \). \( \square \)
The algebraic variety \( W \) is our central object in this article. We will use the notations

\[
W(\mathbb{R})^+ = G(\mathbb{R})/Z_G(M)(\mathbb{R}) = \{ \phi \in W(\mathbb{R}) : \phi \circ x_0 \in X \}
\]

and

\[
W(\mathbb{Q})^+ = W(\mathbb{R})^+ \cap W(\mathbb{Q}) = \{ \phi \in W(\mathbb{Q}) : \phi \circ x_0 \in \mathcal{H}^g(x_0) \}.
\]

The subset \( W(\mathbb{R})^+ \subset W(\mathbb{R}) \) is a union of some connected components of \( W(\mathbb{R}) \). With these notations, Lemma 2.5 implies that we have a bijection

\[
W(\mathbb{Q})^+ \sim \mathcal{H}^g(x_0) \quad \phi \mapsto \phi \circ x_0.
\]

2.2. Functoriality of Generalised and Geometric Hecke orbits.

2.2.1. Restriction to special subvarieties. The following is a set theoretic tautology.

**Proposition 2.6.** Let \((G', X')\) be a Shimura datum with \( M \leq G' \leq G \) and \( X_M \subset X' \subset X \), and define \( K' = G'(\mathbb{A}_f) \cap K \).

1. Let \( \mathcal{H}'(x_0) \) be the generalised Hecke orbit of \( x_0 \) viewed as a point of \( X' \).
   Then
   \[
   \mathcal{H}'(x_0) = \mathcal{H}(x_0) \cap X'.
   \]

2. Let \( \mathcal{H}'([x_0, 1]) \) be the generalised Hecke orbit of \([x_0, 1]\) viewed as a point of \( Sh_{K'}(G', X') \), and \( S' \) the image of
   \[
   f := Sh(\iota) : Sh_{K'}(G', X') \rightarrow Sh_K(G, X)
   \]
   where \( \iota : G' \rightarrow G \) is the inclusion. Then
   \[
   \mathcal{H}([x_0, 1]) \cap S' = f(\mathcal{H}'([x_0, 1])) \quad \text{and} \quad \mathcal{H}'([x_0, 1]) = f^{-1}(\mathcal{H}([x_0, 1])).
   \]

The following corollary can be deduced by combining Lemma 2.5 with Th. 2.4 (it can also be deduced from [45]).

**Corollary 2.7.** We keep previous notations. Then

\[
\mathcal{H}^g(x_0) \cap X'
\]

is a finite union of geometric Hecke orbits in \( X' \).

Accordingly, \( f^{-1}(\mathcal{H}^g([x_0, 1])) \) is the image of finitely many geometric Hecke orbits in \( Sh_{K'}(G', X') \).
2.2.2. **Compatibility to products.** A useful property of geometric Hecke orbits is the compatibility with respect to products of Shimura data.

**Lemma 2.8.** Let \((G, X)\) be an adjoint Shimura datum, and factor \(G = G_1 \times \ldots \times G_f\) as a product of its \(\mathbb{Q}\)-defined simple normal subgroups, and assume \(K = K_1 \times \ldots \times K_f\) for compact open subgroups \(K_i \leq G_i(\mathbb{A})\).

We denote \(X = X_1 \times \ldots \times X_f\) the corresponding factorisation, and choose \(x_0 = (x_1, \ldots, x_f) \in X_1 \times \ldots \times X_f\). We denote \(\mathcal{H}^g(x_i)\) the geometric Hecke orbit of \(x_i\) with respect to the Shimura datum \((G_i, X_i)\).

With respect to the corresponding factorisation of Shimura varieties \(\text{Sh}_K(G, X) = \text{Sh}_{K_1}(G_1, X_1) \times \ldots \times \text{Sh}_{K_f}(G_f, X_f)\)

we have

\[
\mathcal{H}^g(x_0) = \mathcal{H}^g(x_1) \times \ldots \times \mathcal{H}^g(x_f).
\]

It follows from Lemma 2.8 that, at the level of Shimura varieties,

\[
\mathcal{H}^g([x_0, 1]) = \mathcal{H}^g([x_1, 1]) \times \ldots \times \mathcal{H}^g([x_f, 1]).
\]

**Proof.** Since \(G\) is adjoint, we have a factorisation \(X = X_1 \times \ldots \times X_f\).

Let \(M\) be the Mumford-Tate group of \(x_0\) and let \(\phi_0 = (\phi_1, \ldots, \phi_f) : M \to G = G_1 \times \ldots \times G_f\) be the inclusion. As the conjugacy class in a product is the product of conjugacy classes, we have

\[
G \cdot \phi_0 = G_1 \cdot \phi_1 \times \ldots \times G_f \cdot \phi_f.
\]

The Mumford-Tate group of \(x_i\) is \(M_i := \phi_i(M)\). Because \(x_0(S)\) is Zariski dense over \(\mathbb{Q}\) in \(M\) so is \(x_i(S)\) in \(M_i\). Let \(\phi'_i : M_i \to G_i\) be the identity map. We can identify \(G_i \cdot \phi_i \simeq G_i \cdot \phi'_i\), and have

\[
\mathcal{H}^g(x_i) = \{g \cdot \phi'_i \circ x_i : g \in G_i\} \cap X_i = \{g \cdot \phi_i \circ x_i : g \in G_i\} \cap X_i.
\]

The rest follows from the definition of geometric Hecke orbits. \(\square\)

2.2.3. **Passing to the adjoint Shimura datum.** The following property is used to reduced the proof of Conjecture 1.1 and Theorem 1.2 to the case where \(G\) is adjoint.

**Lemma 2.9.** Let \(ad : (G, X) \to (G^\text{ad}, X^\text{ad})\) be the map of Shimura data induced by the natural morphism \(ad : G \to G^\text{ad}\) and choose a compact open subgroup \(K^\text{ad} \leq G^\text{ad}(\mathbb{A}_f)\) containing \(ad(K)\). Let \(ad : x \mapsto x^\text{ad} := ad \circ x\) be the map \(X \to X^\text{ad}\) and

\[
\text{Sh}(ad) : \text{Sh}_K(G, X) \to \text{Sh}_{K^\text{ad}}(G^\text{ad}, X^\text{ad})
\]

the corresponding morphism of Shimura varieties.
Let \( x_0 \in X \). Recall that \( \mathcal{H}^g(x_0) \) and \( \mathcal{H}^g(x_0^{ad}) \) denote the geometric Hecke orbit of \( x_0 \) and \( x_0^{ad} \) with respect to \( G \) and \( G^{ad} \).

We have
\[
(4) \quad \text{ad}(\mathcal{H}^g(x_0)) \subseteq \text{ad}(X) \cap \mathcal{H}^g(x_0^{ad}).
\]

Lemma 2.9 implies the inclusion
\[
\text{ad}(\mathcal{H}^g(x_0)) \times G(\mathbb{A}_f) \subseteq \mathcal{H}^g(x_0^{ad}) \times G^{ad}(\mathbb{A}_f).
\]
Passing to the quotient, we obtain the following.

**Corollary 2.10.** We have \( \text{Sh}(\text{ad})(\mathcal{H}^g([x_0, 1])) \subseteq \mathcal{H}^g([x_0^{ad}, 1]) \).

We now prove Lemma 2.9.

**Proof.** Choose \( x \in \mathcal{H}^g(x_0) \). Clearly \( x' := \text{ad}(x) \in \text{ad}(X) \subset X^{ad} \).

The Mumford-Tate group of \( x'_0 := \text{ad}(x_0) \) is \( M' := \text{ad}(M) \). We denote by \( \phi': M' \to G^{ad} \) the natural injection. We can write \( x = \phi \circ x_0 \) with \( \phi = g\phi_0 g^{-1} \) and \( g \in G(\overline{\mathbb{Q}}) \). Then \( \phi' := \text{ad}(g)\phi'_0 \text{ad}(g)^{-1} \) is defined over \( \mathbb{Q} \) because the map \( G \cdot \phi_0 \to G^{ad} \cdot \phi'_0 \) between conjugacy classes is a morphism of varieties defined over \( \mathbb{Q} \). One computes \( x' = \text{ad}(gx'_0 g)^{-1} = \text{ad}(g)\text{ad}(x_0)\text{ad}(g)^{-1} = \phi' \circ x'_0 \), where \( x'_0 \in X^{ad} \), and \( \phi \) is defined over \( \mathbb{Q} \) and conjugated to \( \phi'_0 \) over \( \overline{\mathbb{Q}} \); that is: \( x' \in \mathcal{H}^g(x'_0) \).

\[\qed\]

**Remarks.** In (4), the reverse inclusion is also true, but it is not used in this paper, and its proof is left to the interested reader. The inclusion (4) and the proof we have given also applies to general morphisms of Shimura data \( (G, X) \to (G', X') \) instead of just \( (G, X) \to (G^{ad}, X^{ad}) \).

### 2.3. Rational conjugacy of linear representations

The following notable fact will be used at several places in this article. We believe this property is also of independent interest.

**Theorem 2.11** ([6, §12.3, third parag.]). For any algebraic group \( M \) over \( \mathbb{Q} \), any two representations \( \phi, \phi' : M \to GL(n) \) which are defined over \( \mathbb{Q} \) and conjugated under \( GL(n, \overline{\mathbb{Q}}) \) are actually conjugated under \( GL(n, \mathbb{Q}) \).

It follows from the theory of linear representations for which references are for example [23, Ch. XI] for \( \overline{\mathbb{Q}} \), and [6, §12] over \( \mathbb{Q} \). We will only need the case where \( M \) is connected and reductive, and this case can be found for instance in [6, §12.3, third paragraph]. They give a Galois cohomology argument, and the same Galois cohomology argument works in general with a reference to [26, 1.7 Ex.1 p.16, 1969] instead. For reductive groups, it is also possible to reduce the result to
Skolem-Noether theorem. For tori, it can be reduced to the fact that any matrix is rationally conjugated to its canonical companion form.

2.4. **Proof of the finiteness Theorem 2.4.** The strategy will combine an argument for semisimple groups and another for algebraic tori.

**Proposition 2.12.** Let $M$ be a semisimple algebraic group over $\mathbb{Q}$ (resp. $\overline{\mathbb{Q}}$).

1. For all $d \in \mathbb{Z}_{\geq 0}$, the set of linear representations defined over $\mathbb{Q}$ (resp. $\overline{\mathbb{Q}}$)

$$\text{Hom}(M, GL(d))$$

is a finite union of conjugacy classes under $GL(d, \mathbb{Q})$ (resp. under $GL(d, \overline{\mathbb{Q}})$.)

2. Let $G$ be a linear algebraic group over $\mathbb{Q}$ (resp. $\overline{\mathbb{Q}}$). Then the set of homomorphisms defined over $\mathbb{Q}$ (resp. $\overline{\mathbb{Q}}$)

$$\text{Hom}(M, G)$$

is contained (resp. is equal to) a finite union of $G(\overline{\mathbb{Q}})$-conjugacy classes.

For simplicity, we will only give an argument which assumes $M$ is Zariski connected, which is the case considered in the proof of Th. 2.4.

**Proof.** We prove the first assertion. By virtue of Theorem 2.11, it is enough to treat the case where everything is defined over $\overline{\mathbb{Q}}$.

Because $M$ is connected it is enough to prove that there are finitely many conjugacy classes of Lie algebra representations $m \rightarrow gl(d)$.

Equivalently there are finitely many isomorphisms classes of linear representations of $m$ of dimension $d$. For this\(^7\), we refer to [19, §7].

For the second assertion we treat the case where everything is defined over $\overline{\mathbb{Q}}$, which implies the case where everything is defined over $\mathbb{Q}$. It is deduced from the first part by using [45].

We prove Theorem 2.4 combining [54, Lem. 2.6] with Prop. 2.13.

**Proof.** We identify $G$ with its image by a faithful representation $G \rightarrow GL(d)$, and we let $\Sigma = \{ \phi \in \text{Hom}(M, G) : \phi \circ x_0 \in X \}$.

\(^7\)These representations are sums of irreducible representations. By the Theorem of the Highest Weight [19, §7.2, Th. 7.15], the irreducible representations is parametrised by dominant weights. The dimension of irreducible representations are given by Weyl dimension formula [19, §7.6.3, Th. 7.43], from which lower bounds for dimensions are easily derived: there are finitely isomorphism classes of irreducible representations.
Thanks\textsuperscript{8} to [54, Lem. 2.6], we may use Proposition 2.13, and deduce that \( \Sigma = \{ \phi \in \text{Hom}(M,G) : \phi \circ x_0 \in X \} \) is contained in finitely many \( GL(d) \)-conjugacy classes. Using [45], we conclude that \( \Sigma \) is contained in finitely many \( G(\mathbb{Q}) \)-conjugacy classes, thus proving Theorem 2.4. \( \square \)

**Proposition 2.13** (Bounding conjugacy classes). Let \( M \) be a connected reductive \( \mathbb{Q} \)-group, \( M^{\text{der}} \) its derived subgroup and \( T = Z_M(M)^0 \) its connected centre.

A subset \( \Sigma \in \text{Hom}(M, GL(d)) \) is contained in finitely many \( GL(d) \)-conjugacy classes if and only if: there is a finite set of characters \( F \subset X(T) \) such that for every \( \rho \in \Sigma \), all the weights of the representation \( \rho \mid_T : T \to GL(d) \) belong to \( F \).

**Proof.** Because the set of characters is invariant under conjugation, the condition is necessary. We prove that this condition is also sufficient.

We know that two representations of a torus \( T \) are conjugated if and only if they have the same weights, with same multiplicities. As the weights belongs to \( F \), and the dimension \( d \) is fixed, there are only finitely many possibilities for these weights and multiplicities. Hence \( \{ \rho \mid_T : \rho \in \Sigma \} \) is contained in at most finitely many conjugacy classes \( GL(d) \cdot \rho_1 \mid_T, \ldots, GL(d) \cdot \rho_c \mid_T \). Without loss of generality we may assume that there is only one conjugacy class, say \( GL(d) \cdot \rho_1 \mid_T \).

We want to prove that

\[ \text{(5) there are finitely many } \rho \in \Sigma, \text{ up to } GL(d)\text{-conjugation.} \]

Possibly after conjugating, we may assume \( \rho \mid_T = \rho_1 \mid_T \). Because \( M \) is connected, one has \( M = M^{\text{der}} \cdot T \). Thus

\[ \text{(6) } \rho \text{ is determined by } \rho \mid_{M^{\text{der}}} \text{ and } \rho \mid_T. \]

As \( M^{\text{der}} \) and \( T \) commute with each other, \( \rho \mid_{M^{\text{der}}} : M^{\text{der}} \to GL(d) \) factors through \( G' := Z_{GL(d)}(\rho_1(T)) \).

By Proposition 2.12, these \( \rho \mid_{M^{\text{der}}} \) belong to finitely many conjugacy classes \( G' \cdot \rho_{1,1} \mid_{M^{\text{der}}}, \ldots, G' \cdot \rho_{1,e} \mid_{M^{\text{der}}} \). Possibly after conjugating \( \rho \) by some \( g \in G' \), which does not change \( \rho \mid_T \), we have

\[ \rho \mid_T = \rho_1 \mid_T \text{ and } \rho \mid_{M^{\text{der}}} \in \{ \rho_{1,1} \mid_{M^{\text{der}}}; \ldots; \rho_{1,e} \mid_{M^{\text{der}}} \}. \]

In light of (6), this proves (5) and the conclusion follows. \( \square \)

\textsuperscript{8}This is where the property \( \phi \circ x_0 \) is used. This also needs that the image of \( x_0 \) is \( \mathbb{Q} \)-Zariski dense in \( M \).
2.5. **Relation to other notions of Hecke orbits.** The following is not used in the rest of this article, however it clarifies the relation between different notions of Hecke orbits and we believe it to be of independent interest. We compare our generalised and geometric Hecke orbits to the classical Hecke orbits and another notion of “generalised Hecke” orbit found in the literature.

2.5.1. **Relation to the classical definition of Hecke orbit.** Let us recall the notion of the classical Hecke orbit.

**Definition 2.14** (classical Hecke orbit). Define the classical Hecke orbit of \(x_0\) as follows:

\[
\mathcal{H}^c(x_0) = \{ \phi \circ x_0 \in X : \phi \in G(\mathbb{Q})/Z_G(M)(\mathbb{Q}) \} \subset \mathcal{H}(x_0)
\]

and the classical Hecke orbit of \([x_0, 1]\) as

\[
\mathcal{H}^c(x_0) = \{ [x, g] : x \in \mathcal{H}^c(x_0), g \in G(\mathbb{A}_f) \}.
\]

We have a chain of inclusions:

\[
\mathcal{H}^c(x_0) \subset \mathcal{H}^g(x_0) \subset \mathcal{H}(x_0) \tag{7}
\]

\[
\mathcal{H}^c(s_0) \subset \mathcal{H}^g(s_0) \subset \mathcal{H}(s_0). \tag{8}
\]

In general, \(\mathcal{H}^g(x_0)\) is not a finite union of classical Hecke orbits, even when \(G\) is of adjoint type.

**Hecke correspondences.** Recall that the classical Hecke orbit can be described using Hecke correspondences. For \(g \in G(\mathbb{Q})\), the points \(s_0 = [x_0, 1]\) and \(s_g = [g \cdot x_0, 1]\) have a common inverse image by the left, resp. right, finite map in

\[
Sh_K(G, X) \xleftarrow{Sh(Ad_g)} Sh_{K \cap gK \cap g^{-1}}(G, X) \xrightarrow{Sh(Ad_g)} Sh_K(G, X)
\]

where \(Sh(Ad_g)\) is the right map is the Shimura morphism associated to the map of Shimura data \(AD_g : (G, X) \to (G, X)\) induced by the conjugation \(AD_g : G \to G\) and \(Sh(Ad_1)\) is induced by the identity map \(AD_1 : G \to G\).

Likewise generalised Hecke orbits can be interpreted using finite correspondences between Shimura varieties. For a point \(\phi \circ x_0 \in \mathcal{H}(x_0)\), the point \(s_0\) and \(s_{\phi} = [\phi \circ x_0, 1]\) have a common inverse image in

\[
Sh_K(G, X) \xleftarrow{Sh(\phi_0)} Sh_{K \cap \phi \circ K}(M, X_M) \xrightarrow{Sh(\phi)} Sh_K(G, X)
\]

This time the correspondence is induced by a correspondence from the image of \(Sh(\phi_0)\) to that of \(Sh(\phi)\). These are also the smallest special subvarieties containing \(s_0\), resp. \(s_{\phi}\).
2.5.2. Relation to the usual definition of the generalised Hecke orbit.

We compare our notion of generalised Hecke to the “generalised Hecke orbits” used in [24] and [15, 35, 33, 53]. The latter is defined in terms of linear representations.

For any faithful representation $\rho : G \to GL(N)$ over $\mathbb{Q}$, let the “$\rho$-Hecke orbit” be

$$\mathcal{H}^\rho(x_0) := \{ \phi \circ x_0 \in X : \phi \in \text{Hom}(M, G)(\mathbb{Q}), \rho \circ \phi \in GL(N, \mathbb{Q}) \cdot \rho \circ \phi_0 \}.$$

By Theorem 2.11, we also have

$$\mathcal{H}^\rho(x_0) = \{ \phi \circ x_0 \in X : \phi \in \text{Hom}(M, G)(\mathbb{Q}), \rho \circ \phi \in GL(N, \overline{\mathbb{Q}}) \cdot \rho \circ \phi_0 \}.$$

**Proposition 2.15.** The $\rho$-Hecke orbit $\mathcal{H}^\rho(x_0)$ is contained in the generalised Hecke orbit $\mathcal{H}(x_0)$.

The $\rho$-Hecke orbit $\mathcal{H}^\rho(x_0)$ is a finite union of geometric Hecke orbits $\mathcal{H}^\rho(x_0) \cup \ldots \cup \mathcal{H}^\rho(x_k)$.

The first statement is clear from the definition of $\mathcal{H}^\rho(x_0)$. The second statement follows from the second definition of $\mathcal{H}^\rho(x_0)$ and [45].

The number of geometric Hecke orbits is bounded independently from $\rho$ thanks to Theorem 2.4. It is unclear whether we can achieve $\mathcal{H}^\rho(x_0) = \mathcal{H}(x_0)$ for a sufficiently general representation $\rho$.

3. Galois functoriality on the generalised Hecke orbit

In §3.1 and §3.2 we state known definitions and properties for the convenience of the reader. Details can be found, for instance, in [53]. In §3.3 we relate cardinality of Galois orbits and cardinality of orbits in adelic groups. This is essential to our approach to the estimates of §1.3.2 through adelic methods.

3.1. Galois representations. Our statements will use the following terminology.

**Definition 3.1** (Galois representations). Let $(M, X_M)$ be a Shimura datum, let $x_0$ be a point in $X_M$, and let $E \leq \mathbb{C}$ be a subfield.

We say that a continuous homomorphism

$$\rho = \rho_{x_0} : \text{Gal}(\overline{E}/E) \to M(\mathbb{A}_f)$$

is a Galois representation (defined over $E$) for $x_0$ (in $X_M$) if: for any compact open subgroup $K' \leq M(\mathbb{A}_f)$, denoting $[x_0, 1]'$ the image of $(x_0, 1)$ in $\text{Sh}_{K'}(M, X_M)$, we have

$$\sigma([x_0, 1]') = [x_0, \rho_{x_0}(\sigma)]'.$$
In the important case of moduli spaces of abelian varieties, a representation $\rho_{x_0}$ can be directly constructed from the linear Galois action on the Tate module (see [53, 8]).

Here we only need the existence of a $\rho_{x_0}$.

**Proposition 3.2** (Existence of Galois representations). Let $[x_0, 1] \in Sh_{K, M}(M, X_M)(E')$ be a point defined over a field $E' \leq \mathbb{C}$ in a Shimura variety.

Then there exist a finite extension $E/E'$ and a Galois representation defined over $E$ for $x_0$ in $X_M$.

The main ingredient in this proposition is the following, which is part of the definition of canonical models: for any $[x_0, m_0]$, any $m \in M(\mathbb{A}_f)$ and $\sigma \in Aut(\mathbb{C}/E(M, X_M))$,

if $\sigma([x_0, m_0]) = [x', m']$ then $\sigma([x_0, m_0 \cdot m]) = [x', m' \cdot m]$.

The continuity of $\rho_{x_0}$ is used in the following lemma.

**Lemma 3.3.** Let $K$ be an open subgroup of $M(\mathbb{A}_f)$. Then, after possibly replacing $E$ by a finite extension, we have

(11) $\rho_{x_0}(\text{Gal}(\overline{E}/E)) \leq K$.

**Proof.** Such an extension corresponds to the open subgroup $\rho_{x_0}^{-1}(K) \leq \text{Gal}(\overline{E}/E)$. \hfill \Box

**Comments.** If $K$ is sufficiently small so that $K \cap Z_G(M_0)(\mathbb{Q}) = \{1\}$, for instance if $K$ is neat then (see [24]) for any field $E$, there is at most one Galois representation $\rho_{x_0}$ satisfying (11).

3.2. **Functoriality of the Galois representation.** In the next statement we denote by $E(G, X)$ the reflex field of a Shimura datum $(G, X)$. It is a number field over which $Sh(G, X)$ (and hence all the $Sh_K(G, X)$) admits a canonical model.

**Proposition 3.4** (Functoriality). Let $\phi : (M, X_M) \to (G, X)$ be a morphism of Shimura data, and $x_0$ a point in $X_M$.

If $\rho_{x_0}$ is a Galois representation defined over a field $E$ for $x_0$, then

$\phi \circ \rho_{x_0}|\text{Gal}(\overline{E}/E(G, X))$

is a Galois representation defined over $E \cdot E(G, X)$ for $\phi(x_0)$ in $X$.

This follows from the definition and the identity

$\sigma([\phi \circ x, \phi(g)]) = [\phi \circ x', \phi(g')]$ for $[x', g'] = \sigma([x, g])$
which holds when $\sigma \in \text{Aut}(\mathbb{C}/E(M, X_M)E(G, X))$. Equivalently the Shimura morphisms induced by $\phi$ are defined over $E(M, X_M)E(G, X)$. (See [12, 1.14, 5.1].)

The compositum field $E \cdot E(G, X) \leq \mathbb{C}$ is a finite extension of $E$ which does not depend on the morphism $\phi$. With our definition, it also does not depend on the compact open subgroups. As a consequence, Galois representations for points in the same generalised Hecke orbit can be deduced from each other, after passing to the same finite extension $E \cdot E(G, X)/E$.

For future reference we summarise the above statements as follows.

**Proposition 3.5.** We keep the same notations. For any $\sigma \in \text{Gal}(\overline{E}/E(G, X))$, any $g \in G(\mathbb{A}_f)$, and any $\gamma \in G(\mathbb{Q})$, we have

$$\sigma([\gamma \cdot \phi(x_0), g]) = [\gamma \cdot \phi(x_0), \rho'(\sigma) \cdot g]$$

where

$$\rho' := \text{Ad}_\gamma \circ \phi \circ \rho_{x_0} : \sigma \mapsto \gamma \cdot \phi \circ \rho_{x_0}(\sigma) \cdot \gamma^{-1}.$$

is a Galois representation defined over $E \cdot E(G, X)$ for $\gamma \cdot \phi(x_0)$ in $X$.

### 3.3. Galois orbits vs Adelic orbits.

Let $U = \rho_{x_0}(\text{Gal}(\overline{E}/E))$. By definition we have

$$\text{Gal}(\overline{E}/E) \cdot [\phi \circ x_0, g] = [\phi \circ x_0, \phi \circ \rho_{x_0}(\text{Gal}(\overline{E}/E)) \cdot g]$$

$$= G(\mathbb{Q}) \setminus G(\mathbb{Q}) \cdot (\{\phi \circ x_0\} \times \phi(U) \cdot g) \cdot K \cdot /K.$$

The next proposition reduces the estimation of the size of the Galois orbit to that of the $\phi(U)$-orbit $\phi(U) \cdot g \cdot K \cdot /K$.

**Proposition 3.6.** There is a real number $C \in \mathbb{R}_{>0}$ such that

$$\forall (\phi \circ x_0, g) \in \mathcal{H}(x_0) \times G(\mathbb{A}_f), \frac{1}{C} \leq \frac{[\text{Gal}(\overline{E}/E) \cdot [x_0, g]]}{[\phi(U) : \phi(U) \cap K]} \leq 1.$$

After possibly passing to a finite extension of $E$, we may choose $C = 1$.

**Proof.** We want to bound the cardinality of the fibres of the map

$$\phi(U) \cdot g \cdot K/K \rightarrow G(\mathbb{Q}) \setminus G(\mathbb{Q}) \cdot (\{\phi \circ x_0\} \times \phi(U) \cdot g) \cdot K \cdot /K.$$

We first describe the fibres. Let $Z_\phi := Z_G(\phi(M))$. The classical description of Hecke orbits gives an identity

$$G(\mathbb{Q}) \setminus G(\mathbb{Q}) \cdot \{\phi \circ x_0\} \times G(\mathbb{A}_f) \simeq Z_\phi(\mathbb{Q}) \setminus \{\phi \circ x_0\} \times G(\mathbb{A}_f)$$

$$\simeq \{\phi \circ x_0\} \times Z_\phi(\mathbb{Q}) \setminus G(\mathbb{A}_f).$$

(This follows from $G(\mathbb{Q}) \cap \text{Stab}_{G(\mathbb{R})}(\phi \circ x_0) = Z_\phi(\mathbb{Q})$ in $G(\mathbb{R})$. We have embedded $Z_\phi(\mathbb{Q})$ in $G(\mathbb{A}_f)$ in the first line, and in $G(\mathbb{A}_f)$ in the second line.)
Define
\[ \Gamma = Z_{\phi}(\mathbb{Q}) \cap \phi(U). \]
The map (12) can be written as a quotient map
\[ \phi(U) \cdot g \cdot K/K \rightarrow \Gamma \backslash (\phi(U) \cdot g \cdot K/K). \]
It will suffice to bound the order \( |\Gamma| \).

The group \( Z_{\phi}(\mathbb{Q}) \) is discrete in \( G(\mathbf{A}_f) \) because \( Z_{\phi}(\mathbb{R}) \) is compact modulo \( Z(G)(\mathbb{R}) \) and \( Z(G)(\mathbb{Q}) \) is discrete in \( G(\mathbf{A}_f) \) ([53, App. Lem. 5.13]), where \( Z(G) \) is the centre of \( G \). Therefore \( \Gamma \) is compact and discrete, and thus is finite.

We will realise \( \Gamma \) as a finite arithmetic group. We choose a faithful representation \( G \rightarrow GL(N) \) defined over \( \mathbb{Q} \), and identify \( M \) and \( G \) with their images in \( GL(N) \).

We let \( K[m] = \ker(GL(N, \hat{\mathbb{Z}}) \rightarrow GL(N, \mathbb{Z}/(m))) \).

There is a maximal compact subgroup \( K' \) of \( GL(N, \mathbf{A}_f) \) which contains \( K \). In \( GL(N, \mathbf{A}_f) \) all maximal compact subgroups are conjugated: \( K' \) is of the form \( h \cdot GL(N, \hat{\mathbb{Z}}) \cdot h^{-1} \) with \( h \in GL(N, \mathbf{A}_f) \). We may even choose \( h \in GL(N, \mathbb{Q}) \) (this is a consequence of strong approximation for \( GL(N) \)).

Conjugating the representation by \( h^{-1} \) we may assume \( h = 1 \): we have
\[ U \leq K \leq GL(N, \hat{\mathbb{Z}}). \]

If \( m = 3 \) we pass to the finite extension of \( E \) corresponding to the subgroup \( \bar{\rho}_{\varepsilon_0}(U \cap K[m]) \) of \( \text{Gal}(\overline{E}/E) \). In any case we may assume
\[ U \leq K \cap K[m] \leq K[m]. \]

From 3.5, we know that \( \phi = \gamma \phi_{\varepsilon_0} \gamma^{-1} \) for some \( \gamma \in GL(N, \mathbb{Q}) \). It follows that
\[ \phi(U) \leq \gamma K[m] \gamma^{-1}, \]
and thus
\[ \Gamma = Z_{\phi}(\mathbb{Q}) \cap \phi(U) \leq GL(N, \mathbb{Q}) \cap \gamma K[m] \gamma^{-1}. \]
Conjugating by \( \gamma^{-1} \) yields
\[ \gamma^{-1} \cdot \Gamma \cdot \gamma \leq \gamma^{-1} GL(N, \mathbb{Q}) \gamma \cap K[m] \]
\[ = GL(N, \mathbb{Q}) \cap K[m] \]
\[ = \begin{cases} GL(N, \mathbb{Z}) & \text{if } m = 1, \\ \ker(GL(N, \mathbb{Z}) \rightarrow GL(N, \mathbb{Z}/(3))) & \text{if } m = 3. \end{cases} \]
Recall that $|\Gamma| = |\gamma^{-1}\Gamma\gamma|$. We may thus conclude by applying the Lemma below to $\gamma^{-1} \cdot \Gamma \cdot \gamma$. It follows that for $m = 1$, $|\Gamma|$ is bounded independently of $\phi$ and for $m = 3$, $|\Gamma| = 1$. □

**Lemma 3.7.** For every $N$, there is a real number $C(N)$ such that, for every finite subgroup $\Gamma \leq GL(N, \mathbb{Z})$ we have

$$|\Gamma| \leq C(N),$$

and if $\Gamma \leq \ker\left(GL(N, \mathbb{Z}) \to GL(N, \mathbb{Z}/(3))\right)$ then $\Gamma = 1$.

**Proof.** From [38, Lemma 4.19.(Minkowski), p. 232] the kernel has no nontrivial torsion. This implies the second assertion.

This also implies that the reduction map $GL(N, \mathbb{Z}) \to GL(N, \mathbb{Z}/(3))$ is injective on $\Gamma$, thus inducing an embedding of $\Gamma$ in $GL(N, \mathbb{Z}/(3))$.

The first conclusion follows with

$$C(N) = |GL(N, \mathbb{Z}/(3))| = \prod_{i=0}^{N-1} (3^N - 3^i).$$

□

### 4. Invariant Heights on Hecke Orbits.

#### 4.1. Height functions.

**4.1.1. Local affine height functions over $\mathbb{R}$ or $\mathbb{Q}_p$.** Let $W$ be an affine variety over $K = \mathbb{R}$ or $K = \mathbb{Q}_p$. For every affine embedding defined over $K$

$$\iota_K : W \to \mathbb{A}^N_K$$

there is an associated **affine local Weil height** function $H_{\iota_K} : W(K) \to \mathbb{R}_{\geq 0}$ given by

$$H_{\iota_K}(w) = \max\{1; |w_1|_K; \ldots; |w_N|_K\},$$

where $| - |_K$ is the standard absolute value on $K$.

**4.1.2. Affine height functions over $\mathbb{Q}$.** When $W$ and $\iota := \iota_K$ are defined over $\mathbb{Q}$, we can define, for $w \in W(\mathbb{Q})$

$$H_{\iota}(w) = H_{\iota \otimes \mathbb{R}}(w) \cdot H_{\iota, f}(w),$$

with $H_{\iota, f}(w) = \prod_p H_{\iota \otimes \mathbb{Q}_p}(w)$.

We define more generally, for $w = (w_p)_p \in W(\mathbb{A}_f)$,

$$H_{\iota, f}(w) = \prod_p H_{\iota \otimes \mathbb{Q}_p}(w_p).$$
When $W$ and the embedding $\iota_E$, resp. $\iota_{\mathbb{Q}_p}$, resp. $\iota$ are clear from the context, we will simply write

$$H_R = H_{\iota}: H_p = H_{\iota_{\mathbb{Q}_p}}, \quad H_W = H_\iota \quad \text{and} \quad H_f = H_{\iota,f}. \quad (17)$$

Then (14) becomes

$$H_W = H_R \cdot H_f. \quad (18)$$

### 4.2. Polynomial equivalence and functoriality of Heights.

We recall the functoriality properties of heights. See [47] or [5] for corresponding statements about projective Weil heights. See Def. 1.7 for the symbols $\preceq$ and $\simeq$.

**Theorem 4.1** (Functoriality of Heights). Let $\phi: V \to V'$ be a morphism of affine varieties over $\mathbb{R}$, resp. $\mathbb{Q}_p$, resp. $\mathbb{Q}$, and let

$$\iota_R: V \to \mathbb{A}_R^N, \quad \text{resp.} \quad \iota_{\mathbb{Q}_p}: V \to \mathbb{A}_{\mathbb{Q}_p}^N, \quad \text{resp.} \quad \iota: V \to \mathbb{A}_\mathbb{Q}^N$$

be an affine embedding of $V$, and let $\iota'_R: V' \to \mathbb{A}_R^{N'}$, resp. $\iota'_{\mathbb{Q}_p}: V' \to \mathbb{A}_{\mathbb{Q}_p}^{N'}$, resp. $\iota': V' \to \mathbb{A}_\mathbb{Q}^{N'}$ be an affine embedding of $V'$.

Then, as functions on $V(\mathbb{R})$, resp. $V(\mathbb{Q}_p)$, resp. $V(\mathbb{Q})$ and $V(\mathbb{A}_f)$,

$$H_\iota \circ \phi \preceq H_{\iota_E}, \quad \text{resp.} \quad H_{\iota_{\mathbb{Q}_p}} \circ \phi \preceq H_{\iota_{\mathbb{Q}_p}}, \quad \text{resp.} \quad H_\iota \circ \phi \preceq H_{\iota} \quad \text{and} \quad H_{\iota,f} \circ \phi \preceq H_{\iota,f}. \quad (\text{Corollary 4.2})$$

**Corollary 4.2.** Let $V$ be an affine algebraic variety over $\mathbb{R}$, resp. $\mathbb{Q}_p$, resp. $\mathbb{Q}$. Let

$$\iota_R: V \to \mathbb{A}_R^N \quad \text{and} \quad \iota'_R: V \to \mathbb{A}_R^{N'},$$

resp. $\iota_{\mathbb{Q}_p}: V \to \mathbb{A}_{\mathbb{Q}_p}^N$ and $\iota'_{\mathbb{Q}_p}: V \to \mathbb{A}_{\mathbb{Q}_p}^{N'}$,

resp. $\iota: V \to \mathbb{A}_\mathbb{Q}^N$ and $\iota: V' \to \mathbb{A}_\mathbb{Q}^{N'}$

be affine embeddings of $V'$.

Then, as functions on $V(\mathbb{R})$, resp. $V(\mathbb{Q}_p)$, resp. $V(\mathbb{Q})$ and $V(\mathbb{A}_f)$,

$$H_{\iota_E} \simeq H_{\iota_E}, \quad \text{resp.} \quad H_{\iota_{\mathbb{Q}_p}} \simeq H_{\iota_{\mathbb{Q}_p}}, \quad \text{resp.} \quad H_\iota \simeq H_\iota \quad \text{and} \quad H_{\iota,f} \simeq H_{\iota,f}. \quad (\text{Def. 1.7})$$

### 4.3. Galois invariant Height on the Hecke orbit.

Let $S = Sh_K(G, X)$ and $x_0$ be as in §1.1 and $\rho_{x_0}: \text{Gal}(\overline{E}/E) \to M(\mathbb{A}_f)$ be as in (9).

Let $W = G \cdot \phi_0 \subseteq \text{Hom}(M, G)$ be the algebraic variety defined in §2.1. We have $W \cong G/Z_G(M)$. As $M$ is connected, we have an embedding

$$\phi \mapsto d\phi : W \hookrightarrow \text{Hom}(m, g).$$

As $M$ is reductive, the image is closed, by [45].

We choose a lattice $g_\mathbb{Z} \leq g$ such that

$$g_\mathbb{Z} \otimes \mathbb{Z} \leq g \otimes \mathbb{A}_f$$
We choose a basis of $g$s where this induces an affine embedding 
\[ \gamma \in \text{Gal}(E/E) \]  
Hence, there exists $\sigma \in \text{Gal}(E/E)$ such that 
\[ (19) \quad \sigma(s_1) = s_2. \] 
Then 
\[ H_f(g_1^{-1}\phi_1 g_1) = H_f(g_2^{-1}\phi_2 g_2). \] 

Proposition 4.3 \textit{(Galois invariance)}. Let $\phi_1, \phi_2 \in W(\mathbb{Q})$ be such that $s_1 = [\phi_1 \circ x_0, g_1]$ and $s_2 = [\phi_2 \circ x_0, g_2]$ define points in $H^0(s_0)$, where $g_1, g_2 \in G(\mathbb{A}_f)$, and assume that there exists a $\sigma \in \text{Gal}(E/E)$ such that 
\[ (19) \quad \sigma(s_1) = s_2. \] 
Then 
\[ H_f(g_1^{-1}\phi_1 g_1) = H_f(g_2^{-1}\phi_2 g_2). \] 

Proof of Prop. 4.3. We define $u = \rho_{x_0}(\sigma) \in M(\mathbb{A}_f) \cap K$. From (19) and the functoriality of Galois action Prop. 3.4, we have 
\[ [\phi_1 \circ x_0, \phi_1(u) \cdot g_1] = [\phi_2 \circ x_0, g_2]. \] 
Hence, there exists $\gamma \in G(\mathbb{Q})$ and $k \in K$ such that 
\[ (\gamma \cdot \phi_1 \circ x_0, \gamma \cdot \phi_1(u)g_1 k) = (\phi_2 \circ x_0, g_2). \] 
By Lemma 2.5, we also have $\gamma \cdot \phi_1 \circ \gamma^{-1} = \phi_2$. Thus 
\[ g_2^{-1}\phi_2 g_2 = (k^{-1}g_1^{-1}\phi_1(u)^{-1}\gamma^{-1}) \cdot (\gamma \cdot \phi_1 \circ \gamma^{-1}) \cdot (\gamma \cdot \phi_1(u)g_1 k) \] 
\[ = k^{-1}g_1^{-1}\phi_1(u^{-1}) \cdot \phi_1 \circ \phi_1(u)g_1 k. \]
We have
\[ \forall m \in M(A_f), \phi_1(u)^{-1} \cdot \phi_1(m) \cdot \phi_1(u) = \phi_1(u^{-1}mu) = \phi_1 \circ AD_{u^{-1}}(m) \]
and hence
\[ k^{-1}g_1^{-1}\phi_1(u)^{-1} \cdot \phi_1 \cdot \phi_1(u)g_1k = AD_{k^{-1}} \circ (g_1^{-1} \cdot \phi_1 \cdot g_1) \circ AD_{u^{-1}}. \]
We finally have, using (22),
\[ H_f(g_2^{-1}g_1g_2) = H_f(AD_{k^{-1}} \circ (g_1^{-1} \cdot \phi_1 \cdot g_1) \circ AD_{u^{-1}}) = H_f(g_1^{-1} \phi_1 g_1). \]

4.3.1. **Height function on the generalised Hecke orbit** $H([x_0, 1])$. The function $H'_f$ on $\text{Hom}(m_{A_f}, g_{A_f})$ induces, at the level of the $Sh_K(G, X)$, a function $H_{s_0}$ on the generalised Hecke orbit $H(s_0)$, given as follows. For $\phi \in \text{Hom}(m_Q, g_Q)$ such that $\phi \circ x_0 \in X$ and $g \in G(A_f)$, we define
\[ H_{s_0}([\phi \circ x_0, g]) = H'_f(d(g^{-1} \phi g)). \]
The function $H_{s_0}$ depends on the choices we have made, but different choices will produce the same function, up to a bounded factor.

The case $\sigma = 1$ of Prop. 4.3 implies that $H_{s_0}$ is well defined. Proposition 4.3 can then be rephrased as follows.

**Lemma 4.4.** For every $\sigma \in \text{Gal}(\overline{E}/E)$ and $s \in H(s_0)$ we have
\[ H_{s_0}(\sigma(s)) = H_{s_0}(s). \]

5. **Height comparison on Siegel sets**

The main result of this section, Th. 5.16, compares, for rational points of $W = G/Z_G(M)$ contained in a given Siegel set (as in Def. 5.11), the global height $H_W$ of (4.1.2), with its factor $H_f$ in (18) (coming from the finite places). The height $H_W$ is the one appearing in our variant (Th. 7.1) of the Theorem of Pila-Wilkie, and $H_f$ is the height appearing in our Galois bounds (see Theorem 6.4).

Our Th. 5.16 extends a result of Orr, in [34], which is only applicable to elements in $G(Q)$. We work with elements of $W(Q)$ instead. This is crucial to us as, in our strategy §1.4, we are working with geometric Hecke orbits.\(^9\)

This section develops different arguments than those of [34]. They are more flexible, which allows us to obtain a more general result.

\(^9\)In general, when $Z_G(M) \neq \{1\}$, the height of an element $g \in G(Q)$ is not bounded by the height of its image $g \phi_0 g^{-1}$ in $W(Q)$ and not every element of $W(Q)$ is the image of an element of $G(Q)$. 
5.1. **Polynomial equivalence and archimedean height.** We use Def. 1.7.

**Lemma 5.1.** Let $A \subset \mathbb{R}^n$ be a semialgebraic subset, and let $f, g: A \rightarrow \mathbb{R}_{\geq 0}$ be semialgebraic and continuous functions. Assume that $f$ is a proper map.

Then

$$g \preccurlyeq f.$$  

**Proof.** We claim that the following function

$$h: ]\inf_A(f), \infty[ \rightarrow \mathbb{R}_{\geq 0}$$

$$t \mapsto \sup\{g(a) : a \in A, f(a) \leq t\}$$

is well defined. Fix an arbitrary $t$ be in $]\inf_A(f), \infty[$. The set $\{a \in A : f(a) \leq t\}$ is compact since $f$ is proper. It is nonempty since $t > \inf_A(f)$. As $g$ is continuous, $\{g(a) : a \in A, f(a) \leq t\}$ is compact and nonempty, and its maximum belongs to $\mathbb{R}_{\geq 0}$, which proves the claim.

The function $h$ is also semialgebraic (see [3, Prop 2.2.4.]). By [57] (§ 4.1 ‘Notes and comments’ and references therein), $h$ is polynomially bounded. The conclusion follows. \hfill \Box

The following uses Lemma 5.1 for $f$ and $g$, and again after swapping $f$ and $g$.

**Corollary 5.2.** On a semialgebraic subset $A \subset \mathbb{R}^n$, two proper semialgebraic continuous functions $f, g: A \rightarrow \mathbb{R}$ are polynomially equivalent.

We will also encounter the following situation.

**Lemma 5.3.** Let $A \subset \mathbb{R}^n$ and $B \subset \mathbb{R}^m$ be semialgebraic subsets, and $f: A \rightarrow \mathbb{R}_{\geq 0}$ and $g: B \rightarrow \mathbb{R}_{\geq 0}$ be two proper semialgebraic continuous functions, and $p: A \rightarrow B$ be a proper and continuous semialgebraic function. Then $g \circ p \approx f$.

**Proof.** We note that $g \circ p$ is proper and continuous because $g$ and $p$ are. We can apply the Corollary 5.2 to $f$ and $g \circ p$. \hfill \Box

5.1.1.

**Lemma 5.4.** Let $V$ be an affine algebraic variety over $\mathbb{R}$. Let $\phi: V \rightarrow \mathbb{A}^N$, and $\phi': V \rightarrow \mathbb{A}^M$ be two closed embeddings, and let $H_{\phi}$ and $H_{\phi'}$ be defined as in (13).

Then $H_{\phi}$ and $H_{\phi'}$ are semialgebraic continuous proper functions, and

$$H_{\phi} \approx H_{\phi'}.$$
Proof. The real algebraic map \( V(\mathbb{R}) \to \mathbb{R}^N \) induced by the Zariski closed embedding \( \phi \) is a closed embedding for the real topology. The functions \( \| \|_\infty : \mathbb{R}^N \to \mathbb{R}_{\geq 0} \) and \( t \mapsto \max\{1; t\} : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0} \) are semialgebraic continuous proper maps. The composite map \( H_\phi \), and likewise \( H_{\phi^*} \), are thus semialgebraic continuous and proper on \( V(\mathbb{R}) \).

We conclude with Cor. 5.2.

5.1.2.

Lemma 5.5. Let \( p : U \to V \) be a morphism of affine algebraic varieties over \( \mathbb{R} \), and \( \phi_U : U \to \mathbb{A}^N_\mathbb{R} \) and \( \phi_V : V \to \mathbb{A}^M_\mathbb{R} \) be closed embeddings. Let \( H_{\phi_U} \) and \( H_{\phi_V} \) be defined as in (13).

Let \( A \subset U(\mathbb{R}) \) be a semialgebraic subset such that \( p|_A : A \to V(\mathbb{R}) \) is proper. Then, as functions \( A \to \mathbb{R}_{\geq 0} \),

\[
H_{\phi_U}|_A \approx H_{\phi_V} \circ p|_A.
\]

Proof. We know that \( H_{\phi_U} \) and \( H_{\phi_V} \) are proper continuous and semi-algebraic. As \( p|_A \) is proper, \( \tilde{t} : A \to U(\mathbb{R}) \) is closed. It follows that \( H_{\phi_U}|_A = H_{\phi_U} \circ \tilde{t} \) is continuous, proper and semi-algebraic. We apply Lemma 5.3 with \( A = U(\mathbb{R}) \), and \( B = V(\mathbb{R}) \), and \( p|_A \) as \( p \), and \( f = H_{\phi_U}|_A \) and \( g = H_{\phi_V} \).

5.2. Comparison of archimedean and finite height.

Lemma 5.6. Let \( \iota : V \to \mathbb{A}^M_\mathbb{R} \) be a closed embedding with \( V = \mathbb{G}_m^N \).

Then \( H_{\iota; \mathbb{R}} \preceq H_{\iota; \mathbb{R}} \) on \( \mathbb{Q}^\times \times \mathbb{N} \), where \( H_{\mathbb{R}} \) and \( H_f \) are as in §4.1.2 (17).

Proof. Thanks to Cor. 4.2, we may substitute \( \iota \) with the closed embedding

\[
(24) \quad \iota_N : \mathbb{G}_m^N \oplus \mathbb{A}^N_\mathbb{R} \to \mathbb{A}^N_\mathbb{R}.
\]

We start with the case \( N = 1 \). We write an element \( t \in \mathbb{Q}^\times \) as a reduced fraction \( n/m \). We can compute

\[
H_{\iota_1; \mathbb{R}}(t) = \max\{|t|; |1/t|\} \quad \text{and} \quad H_{\iota_1; \mathbb{R}}(t) = |n \cdot m|.
\]

It follows \( H_{\iota_1; \mathbb{R}}(t) \leq H_{\iota_1; \mathbb{R}}(t) \).

For general \( \tilde{t} = (t_1, \ldots, t_N) \in \mathbb{Q}^\times \times \mathbb{N} \) there is some \( 1 \leq i \leq N \) such that

\[
H_{\iota_N; \mathbb{R}}(\tilde{t}) = \max\{|t_1|; |1/t_1|; \ldots; |t_N|; |1/t_N|\} = \max\{|t_i|; |1/t_i|\}.
\]

By the previous computation we have

\[
H_{\iota_N; \mathbb{R}}(\tilde{t}) = H_{\iota_1; \mathbb{R}}(t_i) \leq H_{\iota_1; \mathbb{R}}(t_i).
\]

We conclude by observing that

\[
H_{\iota_1; \mathbb{R}}(t_i) \leq H_{\iota_N; \mathbb{R}}(\tilde{t}),
\]
as can be seen prime by prime. □

**Lemma 5.7.** For $V = \mathbb{G}_m^N \subset W = \mathbb{A}^N$, and affine embeddings $\iota_V : V \to \mathbb{A}^M$, resp. $\iota_W : W \to \mathbb{A}^{M'}$, we have $H_{\iota_V \cdot f} \leq H_{\iota_W \cdot f}$ on $\mathbb{Q}^N$.

**Proof.** By Cor. 4.2, we may assume that $\iota_V$ is $\iota_N$ of (24), and that $\iota_W$ is the identity map. We can again reduce the problem to the case $N = 1$. We write $t_i = n/m$ as an irreducible fraction and then we have

$$H_{\iota_V \cdot f}(n/m) = |n \cdot m| \leq \max\{|n|, |m|\}^2 = H_{\iota_W}(n/m)^2.$$ □

**Corollary 5.8.** Let $C \in \mathbb{R}_{>0}$. We have

$$H_{\iota_V \cdot f} \leq H_{\iota_W \cdot f} \text{ on } (\mathbb{Q}^\times \cap [-C; C])^N.$$ 

**Proof.** In the Lemma, we decompose $H_{\iota_W} = H_{\iota_W \otimes \mathbb{R}} \cdot H_{\iota_W \cdot f}$. By hypothesis, $H_{\iota_W \otimes \mathbb{R}} \leq C$, hence $H_{\iota_W} \leq H_{\iota_W \cdot f}$ on $(\mathbb{Q}^\times \cap [-C; C])^N$ which allows us to conclude. □

We establish the following.

**Proposition 5.9.** Let $W$ be an affine variety over $\mathbb{Q}$ and let $p : W \to \mathbb{A}^r$ be an algebraic map and $\mathcal{S} \subset W(\mathbb{R})$ be a semialgebraic closed subset such that

1. we have $p(\mathcal{S}) \subseteq (\mathbb{R}^\times)^r$;
2. the restriction $p|_{\mathcal{S}} : \mathcal{S} \to \mathbb{R}^r$ is a proper map;
3. the image $p(\mathcal{S})$ is bounded in $\mathbb{R}^r$.

We fix an affine embedding $\iota$ of $W$ and use notations (17). Then

$$H_{\mathcal{S}}|_{\mathbb{Q} \cap W(\mathbb{Q})} \leq H_{f|_{\mathcal{S} \cap W(\mathbb{Q})}}.$$ 

In particular

$$H_{W|_{\mathcal{S} \cap W(\mathbb{Q})}} \approx H_{f|_{\mathcal{S} \cap W(\mathbb{Q})}}.$$ 

**Proof.** We denote by $\mathbb{G}_m^r \subset \mathbb{A}^r$ the affine open subset on which every coordinate is invertible.

We fix affine embeddings $\iota_W$ of $W$, and $\iota_{\mathbb{G}^r_m}$ of $\mathbb{G}_m^r$ and $\iota_{\mathbb{A}^r}$ of $\mathbb{A}^r$.

Because $p|_{\mathcal{S}}$ is continuous real algebraic, and (as a function to $\mathbb{R}^r$) is proper, by Lemma 5.5 we have

$$H_{\iota_W \otimes \mathbb{R}}|_{\mathcal{S}} \approx H_{\iota_{\mathbb{G}^r_m} \otimes \mathbb{R}} \circ p|_{\mathcal{S}}.$$ 

By functoriality of heights Th. 4.1, we have, on $W(\mathbb{Q})$,

$$H_{\iota_{\mathbb{A}^r} \cdot f} \circ p \leq H_{\iota_W \cdot f}.$$ 

As $p(\mathcal{S})$ is bounded in $\mathbb{R}^r$, we have, by Lemma 5.6,

$$H_{\iota_{\mathbb{G}^r_m} \otimes \mathbb{R}} \leq H_{\iota_{\mathbb{G}^r_m} \cdot f}.$$
By hypothesis 3 we can use Corollary 5.8 and get

\[(28) \quad H_{\iota_\mathfrak{g}\mathfrak{m}_r\cdot f|p(\mathfrak{g})\cap Q^{x r}} \leq H_{\iota_\mathfrak{g}_r\cdot f|p(\mathfrak{g})\cap Q^{x r}}.\]

Combining these we get, using (25), (27), (28) and then (26),

\[H_{\iota_\mathfrak{w}\otimes R} \otimes W(Q) \approx H_{\iota_\mathfrak{g}_M\cdot R} \circ p(\mathfrak{w}^\otimes W(Q) \leq H_{\iota_\mathfrak{g}_r\cdot f} \circ p(\mathfrak{w}^\otimes W(Q) \leq H_{\iota_\mathfrak{w} \cdot f} \otimes R \otimes W(Q). \]

\[\square\]

5.3. Construction of Siegel sets. We start by recalling some facts about parabolic subgroups and Siegel sets. A general reference is [4].

Let \( G_\mathbb{Q} \) be a semisimple \( \mathbb{Q} \)-algebraic group of adjoint type. We fix a minimal \( \mathbb{Q} \)-defined parabolic\(^1\) subgroup \( P_\mathbb{Q} \). Let \( G_\mathbb{R} \) and \( P_\mathbb{R} \) be the corresponding \( \mathbb{R} \)-algebraic groups.

Let \( X \) be the associated symmetric space\(^2\), and choose \( x \in X \) and let \( \Theta : G_\mathbb{R} \to G_\mathbb{R} \) be the Cartan involution associated with \( x \). The orbit map \( g \to g \cdot x \) induces the identification \( G(\mathbb{R})/K \simeq X \) where \( K \) is the maximal compact subgroup \( \{ g \in G(\mathbb{R}) : g = \Theta(g) \} \). We denote \( K_\infty = K^+ \) the neutral component.

We let \( N_\mathbb{Q} \) be the unipotent radical of \( P_\mathbb{Q} \): thus \( P_\mathbb{Q}/N_\mathbb{Q} \) is the maximal reductive quotient of \( P_\mathbb{Q} \). The \( \mathbb{R} \)-algebraic group

\[L := P_\mathbb{R} \cap \Theta(P_\mathbb{R})\]

is a maximal \( \mathbb{R} \)-algebraic reductive subgroup of \( P_\mathbb{R} \) (cf. [4, §III.1.9]), not necessarily defined over \( \mathbb{Q} \), and the map \( L \to P_\mathbb{R} \to (P_\mathbb{Q}/N_\mathbb{Q})_\mathbb{R} \) is an isomorphism. We denote by \( A'_\mathbb{Q} \) the maximal central \( \mathbb{Q} \)-split torus of \( P_\mathbb{Q}/N_\mathbb{Q} \), and define \( A \leq L \) as the inverse image of \( A_\mathbb{R} \) in \( L \). We denote by \( A^+ = A(\mathbb{R})^+ \) the neutral component as a real Lie group.

We denote by \( \Phi \) the set of non-zero weights of the adjoint action of \( A \) on \( \mathfrak{g} \otimes \mathbb{R} \) (the “(relative) roots”), and \( \Phi^+ \) the subset of weights of the action on \( \mathfrak{n} \otimes \mathbb{R} \) (the “positive” ones). The eigenspaces are not necessarily defined over \( \mathbb{Q} \). There exists a unique subset \( \Delta = \{ \alpha_1; \ldots ; \alpha_r \} \subset \Phi^+ \) such that \( \alpha_1, \ldots , \alpha_r \) is a basis of \( X(A) = \text{Hom}(A, \mathbb{G}_{m, \mathbb{R}}) \) and \( \Phi^+ \subset \alpha_1 \cdot \mathbb{Z}_{\geq 0} + \cdots + \alpha_r \cdot \mathbb{Z}_{\geq 0} \). The \( \alpha_i \) are known as the (relative) simple roots, and \( r \) is equal to the \( \mathbb{Q} \)-rank of \( G_\mathbb{Q} \).

\(^{10}\)Non necessarily proper: we have \( P_\mathbb{Q} = G_\mathbb{Q} \) when \( G_\mathbb{Q} \) is of \( \mathbb{Q} \)-rank zero.

\(^{11}\)The space \( X \) in this section is of the form \( G(\mathbb{R})/K \) with \( K \) a non necessarily connected maximal compact subgroup. This \( G(\mathbb{R})/K \) is connected and is a quotient of the space \( X = G(\mathbb{R})/K_\infty \) from other sections of this article: when \( x \) is the image of \( x_0 \in G(\mathbb{R})/K_\infty \), we have \( K_\infty = K^+ \), where for simplicity we assume \( G \) is of adjoint type. The point \( x_0 \) determines and is determined by a Hodge cocharacter \( h : \mathbb{S} \to G_\mathbb{R} \), and the image point \( x \in G(\mathbb{R})/K \) determines and is determined by the corresponding Cartan involution \( \Theta = Ad_{h(i)} \).
The positive Weyl chamber in $A^+$ is
\[(29) \quad A^+_{\geq 0} = \{ a \in A^+ : \forall 1 \leq i \leq r, \alpha_i(a) \geq 1 \}.
\]
We define
\[(30) \quad H_Q := \cap_{\chi \in X(P_Q)} \ker(\chi^2).
\]
We note that, for every one-dimensional representation $Q \cdot \eta$ of $H_P$, we have
\[(31) \quad \forall h \in H_P(\mathbb{R}), \; h \cdot \eta \in \{ +\eta; -\eta \}.
\]
We first define Siegel sets in $G_Q(\mathbb{R})$.

**Definition 5.10 (Siegel set).** A $Q$-Siegel set $\mathcal{S}$ in $G_Q(\mathbb{R})$ with respect to $P_Q$ and $x$ is a subset $\mathcal{S} \subseteq G(\mathbb{R})$ of the following form.

There is a nonempty open and relatively compact subset $\Omega \subseteq P_Q(\mathbb{R})$ and an element $a \in A^+$ such that
\[
\mathcal{S} = \Omega \cdot A^+_{\geq 0} \cdot a \cdot K^\infty.
\]
We will always assume that $\Omega \subseteq H_Q(\mathbb{R})$ and that $\Omega$ is semialgebraic.

Usually Siegel sets are defined in $G_Q(\mathbb{R})$ or in $X = G_Q(\mathbb{R})/K$. Working with Geometric Hecke orbits as defined in Def. 2.3, we use the variety $W(\mathbb{R})^+ = G(\mathbb{R})/Z_G(M)(\mathbb{R})$. We can view $W(\mathbb{R})^+$ as an intermediary space in the sequence of maps $G(\mathbb{R}) \to W = G(\mathbb{R})/Z_G(M)(\mathbb{R}) \to X$. The following definition allows us to work with Siegel sets in a greater generality.

**Definition 5.11.** Let $Z$ be a compact subgroup of $K$, and $W = G_R/Z$. We define a $Q$-Siegel set $\mathcal{S}_W$ with respect to $P_Q$ and $x$ in $W^+ := G_R(\mathbb{R})/Z(\mathbb{R})$ to be the image of $Q$-Siegel set $\mathcal{S}$ in $G_Q(\mathbb{R})$ with respect to $P_Q$ and $x$.

We note that if $Z$ is defined over $\mathbb{Q}$ then so is $W$ and we can consider the subset $W^+(\mathbb{Q}) \cap \mathcal{S}_W$.

### 5.4. Divergence in Siegel sets.

In the rest of this section we use the notations $\tilde{G} = G_Q$.

#### 5.4.1. We say that an infinite sequence, in an appropriate topological space, is divergent if it does not contain an infinite convergent subsequence. A continuous map is proper if it maps divergent sequences to divergent sequences.
5.4.2. We will use the closure of a Siegel set.

**Proposition 5.12.** Consider $\mathcal{S} = \Omega \cdot A^+_{\geq 0} \cdot a \cdot K_\infty$ as in Def. 5.10. Then its closure in $G(\mathbb{R})$ is given by

$$S = \overline{\mathcal{S}} = \Omega \cdot A^+_{\geq 0} \cdot a \cdot K_\infty. \quad (32)$$

and $\overline{\mathcal{S}}$ is contained in a $\mathbb{Q}$-Siegel set $\mathcal{S}'$ in $G(\mathbb{R})$ with respect to $P$ and $x$.

**Proof.** The set $\mathcal{S}$ is obviously dense in the right-hand side of (32). It is the image of the proper map in Lemma 5.13, and thus it is a closed subset in $G(\mathbb{R})$. This proves the first assertion. Let $U$ be a nonempty relatively compact semialgebraic open neighbourhood of 1 in $H(\mathbb{R})$, for instance a small euclidean open ball in a faithful representation $H \to GL(N)$. Then $\Omega' = U \cdot \overline{\mathcal{S}}$ is an open relatively compact semialgebraic open neighbourhood of $\overline{\mathcal{S}}$ in $H(\mathbb{R})$, and the Siegel set $\Omega' \cdot A^+_{\geq 0} \cdot a \cdot K$ contains $\overline{\mathcal{S}}$. □

We used the following.

**Lemma 5.13.** The map

$$(\omega, a, k) \mapsto \omega \cdot a \cdot k : \Omega \times A^+_{\geq 0} \cdot a \times K \to G(\mathbb{R})$$

is proper.

**Proof.** It suffices to prove that the image of every divergent sequence in the left hand-side is not a convergent sequence in the right hand-side. We prove the contrapositive.

Let $(\omega_n, a_n, k_n)_{n\in\mathbb{Z}_{\geq 1}}$ be a sequence in the left-hand-side such that $(\omega_n \cdot a_n \cdot k_n)_{n\in\mathbb{Z}_{\geq 1}}$ is a convergent sequence in $G(\mathbb{R})$. Because $\Omega$ and $K$ are compact, after possibly extracting a subsequence we may assume that $(\omega_n)_{n\in\mathbb{Z}_{\geq 1}}$ and $(k_n)_{n\in\mathbb{Z}_{\geq 1}}$ are convergent sequences. It follows that $(a_n)_{n\in\mathbb{Z}_{\geq 1}}$ is a convergent subsequence. We recall that $(\alpha_1, \ldots, \alpha_r) : A^+ \to \mathbb{R}_{>0}^r$ is an isomorphism. It follows that $A^+_{\geq 0}$ is closed in $A^+$. Because $A(\mathbb{R})$ is a closed subgroup of $G(\mathbb{R})$, that $A^+$ is a closed subgroup of $A(\mathbb{R})$, this $A^+_{\geq 0}$ is closed in $G(\mathbb{R})$. One deduces that $A^+_{\geq 0} \cdot a$ is closed in $G(\mathbb{R})$ and that the limit of $(a_n)_{n\in\mathbb{Z}_{\geq 1}}$ in $G(\mathbb{R})$ belongs to $A^+_{\geq 0} \cdot a$.

We proved that the original sequence $(\omega_n, a_n, k_n)_{n\in\mathbb{Z}_{\geq 1}}$ contains a convergent infinite subsequence. Thus it is not a divergent sequence. □

These results have the following consequence.

**Corollary 5.14.** A sequence $(\omega_n \cdot a_n \cdot k_n)_{n\in\mathbb{Z}_{\geq 1}}$ is divergent in $\overline{\mathcal{S}}$ if and only if $a_n$ is divergent in $A^+_{\geq 0}$. 

Proof. Because $\overline{\mathfrak{S}}$ is closed, $(\omega_n \cdot a_n \cdot k_n)_{n \in \mathbb{Z}_{\geq 1}}$ is also divergent in $G(\mathbb{R})$. It follows that the sequence $(\omega_n, a_n, k_n)_{n \in \mathbb{Z}_{\geq 1}}$ contains no convergent subsequence. Because $\overline{\Omega}$ and $K$ are compact, the projection map

$$\overline{\Omega} \times A_{\geq 0}^+ \cdot a \times K \to A_{\geq 0}^+ \cdot a$$

is proper. It follows that the image sequence $(a_n)_{n \in \mathbb{Z}_{\geq 1}}$ is divergent in $A_{\geq 0}^+ \cdot a$. $\square$

5.4.3. Let $P_1, \ldots, P_r$ be the maximal $\mathbb{Q}$-defined proper parabolic subgroups of $G$ containing $P$. We denote by $N_i$ their unipotent radicals, and $n_i$ the (Q-linear) Lie algebra of $N_i$. The adjoint representation of $G$ induces an action of $G$ on the Q-vector space $V_i = \bigwedge^{\dim(N_i)} \mathfrak{g}$. Then the Q-vector subspace $\bigwedge^{\dim(N_i)} n_i \leq V_i$ is of dimension 1, and we choose a generator $\eta_i$ of this Q-line.

Then the $\mathbb{R}$-line $\mathbb{R} \cdot \eta_i$ is an eigenspace of $A$ acting on $V_i \otimes \mathbb{R}$, and this eigenspace is defined over $\mathbb{Q}$. Let $\chi_i$ be the corresponding eigencharacters of $A$: we have

$$\forall a \in A(\mathbb{R}), \forall 1 \leq i \leq r, a \cdot \eta_i = \chi_i(a) \cdot \eta_i.$$  

For $1 \leq i \leq r$ the $\chi_i$ are positive multiples $k_1 \cdot \omega_1, \ldots, k_r \cdot \omega_r$ of the (relative) fundamental weights of $\omega_1, \ldots, \omega_r \in X(A) \otimes \mathbb{Q}$. In particular

$$\forall \alpha \in A^+_{\geq 0}, \forall 1 \leq i \leq r, \chi_i(a)^{-1} \leq 1.$$  

One knows that the fundamental weights are positive $\mathbb{Q}$-linear combinations of the $\alpha_i$ and that they form a basis of $X(A) \otimes \mathbb{Q}$. The same holds for the $\chi_i$. We deduce the following.

Lemma 5.15. Let $(a_n)_{n \in \mathbb{Z}_{\geq 0}}$ be a sequence in $A^+_{\geq 0} \cdot a$. Then the sequence is divergent (no infinite subsequence is convergent) if and only if

$$\lim_{n \to \infty} \min_{1 \leq i \leq r} \chi_i(a_n)^{-1} = 0.$$  

Proof. If $(a_n)_{n \in \mathbb{Z}_{\geq 0}}$ contains a convergent infinite subsequence, then the sequence $(\min_{1 \leq i \leq r} \chi_i(a_n)^{-1})_{n \in \mathbb{Z}_{\geq 0}}$ contains a convergent infinite subsequence in $\mathbb{R}_{\geq 0}$ and we cannot have (35).

This proves one implication and we now prove the other.

Assume that (35) fails. Equivalently

$$L := \limsup_{n \to \infty} \min_{1 \leq i \leq r} \chi_i(a_n)^{-1} > 0.$$  

There are none if $r = 0$.  

The “weights lattice” $\omega_1 \cdot \mathbb{Z} + \ldots + \omega_r \cdot \mathbb{Z} \subseteq X(A)$ can be identified with $X(\tilde{A})$ where $\tilde{A}$ is the torus in a simply connected cover $\tilde{G}_\mathbb{R} \to G_\mathbb{R}$ which maps onto $A$.  

---

12There are none if $r = 0$.  

13The “weights lattice” $\omega_1 \cdot \mathbb{Z} + \ldots + \omega_r \cdot \mathbb{Z} \subseteq X(A)$ can be identified with $X(\tilde{A})$ where $\tilde{A}$ is the torus in a simply connected cover $\tilde{G}_\mathbb{R} \to G_\mathbb{R}$ which maps onto $A$.  

---
After possibly extracting a subsequence, we have
\begin{equation}
\lim_{n \to \infty} \min_{1 \leq i \leq r} \chi_i(a_n)^{-1} = L \neq 0.
\end{equation}
Because the \(a_n\) belong to \(A^+\), we have \(\sup_{n \in \mathbb{Z}_{\geq 0}} a_i(a_n)^{-1} \leq \alpha_i(a)^{-1}\) for every \(1 \leq i \leq r\). Because the \(\chi_i\) are positive linear combination of the \(\alpha_i\), the \(\chi_i(a_n)^{-1}\) are bounded above. According to (36) they are bounded below in \(\mathbb{R}_{>0}\). Because the \(\chi_i\) form a basis of \(X(A) \otimes \mathbb{Q}\), the \(\alpha_i\) are linear combination of the \(\chi_i\). Hence the \(\alpha_i(a_n)\) are bounded above and below in \(\mathbb{R}_{>0}\). Equivalently \((a_n)_{n \in \mathbb{Z}_{\geq 0}}\) is bounded in \(A^+\).

This proves the other implication. \(\square\)

5.5. **Height on Siegel sets.** The following statement is the main objective of §5.

**Theorem 5.16.** Let \(G_W\) as in Def. 5.11 with \(Z\) defined over \(\mathbb{Q}\), let \(\iota : G/Z \to \mathbb{A}_\mathbb{Q}^N\) be an affine embedding and let \(H_W = H_{\mathbb{R}} \cdot H_f\) be as in (18). Then, as functions \(G_W \cap W(\mathbb{Q}) \to \mathbb{R}_{\geq 0}\) we have
\[H_W \approx H_f.\]

This will be deduced from Proposition 5.9. We first construct the map \(p\) to which we apply the Proposition, and then verify the assumptions of the Proposition.

5.5.1. **Construction of the morphism \(p\).** Let the \(\eta_i \in V_i = \bigwedge^\dim_n g\) and the \(\chi_i\) be as in §5.4.3.

For each \(1 \leq i \leq r\), we choose a positive definite quadratic form \(Q_i' : V_i \to \mathbb{Q}\).

We denote by \(dz\) the Haar probability measure on \(Z(\mathbb{R})\) we define the real quadratic form
\begin{equation}
Q_i(v) = \int_{Z(\mathbb{R})} Q_i'(z \cdot v) \, dz : V_i \otimes \mathbb{R} \to \mathbb{R}.
\end{equation}

The following is central in our argument.

**Lemma 5.17.** The quadratic form \(Q_i\) is invariant under \(Z(\mathbb{R})\), is definite positive, and is defined over \(\mathbb{Q}\).

**Proof.** The two first properties are immediate from (37). We prove that \(Q_i\) is defined over \(\mathbb{Q}\). Let \(V\) be the \(\mathbb{Q}\)-vector space of quadratic forms, as a representation of \(Z\), and \(V^Z\) be the subspace of elements
fixed by \(Z\). As \(Z(\mathbb{R})\) is compact, the \(\mathbb{Q}\)-group \(Z\) is reductive, and there is a \(Z\)-stable \(\mathbb{Q}\)-subspace \(W\) such that we can decompose
\[V = V^Z \oplus W.\]

Let us write correspondingly
\[Q_i' = Q_i' + Q_W\]
with \(Q_Z\) in \(V^Z\) and \(Q_W\) in \(W\).

Because \(Q_Z\) is invariant under \(Z(\mathbb{R})\) and \(W \otimes \mathbb{R}\) is stable under \(Z(\mathbb{R})\),
\[\int_{Z(\mathbb{R})} z \cdot Q_Z \, dz = Q_Z\] and \(\int_{Z(\mathbb{R})} z \cdot Q_W \, dz \in W \otimes \mathbb{R}\).

By construction \(\int_{Z(\mathbb{R})} z \cdot Q_W \, dz\) is fixed by \(Z(\mathbb{R})\), and thus it belongs to \(W \otimes \mathbb{R} \cap V^Z \otimes \mathbb{R} = \{0\}\). We compute
\[Q_i = \int_{Z(\mathbb{R})} z \cdot Q_i' \, dz = \int_{Z(\mathbb{R})} z \cdot Q_Z \, dz + \int_{Z(\mathbb{R})} z \cdot Q_W \, dz = Q_Z + 0.\]

Because \(Q_Z\) is defined over \(\mathbb{Q}\), so is \(Q_i\). □

We can now define \(p : W \rightarrow \mathbb{A}_\mathbb{Q}^r\) by
\[(38) \quad p(gZ) = (Q_1(g^{-1} \cdot \eta_1), \ldots, Q_r(g^{-1} \cdot \eta_r)).\]

As the \(Q_i\) are defined over \(\mathbb{Q}\) so is \(p\), and as the \(Q_i\) are \(Z\)-invariant, \(p\) is well defined.

5.5.2. Properties of the morphism \(p\). Our next task is to verify the assumptions of Proposition 5.9.

(1) We have \(p(\mathbb{S}_W) \subset (\mathbb{R}^x)^r\).

(2) As a map \(\mathbb{S}_W \rightarrow (\mathbb{R}^x)^r\), \(p|_{\mathbb{S}_W}\) is proper with respect to the real topologies.

(3) the image \(p(\mathbb{S})\) is bounded in \(\mathbb{R}^r\).

Proof of 1. Every point of \(\mathbb{S}_W\) is of the form \(gZ\) with \(g \in G(\mathbb{R})\). The vector \(g \cdot \eta_i\) is thus in \(V_i \otimes \mathbb{R}\). As \(\eta_i \neq 0\) and \(g\) is invertible, \(g^{-1} \cdot \eta_i \neq 0\). As \(Q_i\) is positive definite by Lem. 5.17, we have \(Q_i(g^{-1} \eta_i) \in \mathbb{R}_{>0}\). □

We will use that there exists \(C \in \mathbb{R}_{>0}\) such that for every \(1 \leq i \leq r\),
\[(39) \quad \forall (h, \alpha, k) \in H_P \times A_{\geq 0}^r \times K_\infty, 0 \leq p_i(h \cdot a \cdot \alpha \cdot k) \leq C \cdot \chi_i(\alpha)^{-2}.\]

Proof of (39). We write \(\sigma = h \cdot a \cdot \alpha \cdot k\). By (31), we have \(h^{-1} \cdot \eta_i = \pm \eta_i\). Thus
\[\sigma^{-1} \cdot \eta_i = \pm k^{-1} \cdot \alpha^{-1} \cdot a^{-1} \cdot \eta_i = \pm k^{-1} \cdot \chi_i(\alpha)^{-1} \cdot \eta_i.\]
Because $K$ is compact there exists a $K$-invariant euclidean norm $\| \cdot \|$ on $V_i \otimes \mathbb{R}$. The two norms $\sqrt{Q_i}$ and $\| \cdot \|$ on $V_i \otimes \mathbb{R}$ are comparable: there is $C_i \in \mathbb{R}_{>0}$ such that for any $v \in V_i \otimes \mathbb{R}$,

$$Q_i(v) \leq C_i \cdot \|v\|^2.$$

We deduce (39) with $C = \max_{i \in \{1, \ldots, r\}} C_i \cdot \|a^{-1} \cdot \eta_i\|^2$ from

$$p_i(\sigma) = Q_i(\sigma^{-1} \cdot \eta)$$

$$\leq C_i \cdot \|\pm k^{-1} \cdot \chi_i(\alpha)^{-1} \cdot a^{-1} \cdot \eta_i\|^2$$

$$= C_i \cdot \|\pm \chi_i(\alpha)^{-1} \cdot a^{-1} \cdot \eta_i\|^2$$

$$= C_i \cdot \chi_i(\alpha)^{-2} \cdot \|a^{-1} \cdot \eta_i\|^2 \geq 0. \quad \square$$

**Proof of 2.** For a divergent sequence $\sigma_n = \omega_n a \cdot \alpha_n k_n$ in $\overline{\mathcal{S}}_W$, Cor. 5.14 and Lem. 5.15 imply that $\min_{1 \leq i \leq r} \chi_i(\alpha_n) \to 0$. Using (39), we deduce that

$$\min_{1 \leq i \leq r} p_i(\omega_n a_n a k_n) \to 0.$$

and thus $p(\omega_n a_n k_n)$ is divergent in $\mathbb{R}^r$. This proves the properness. \quad \square

**Proof of 3.** For $\sigma = h \cdot \alpha \cdot a \cdot k \in \overline{\mathcal{S}}$, we have $0 \leq \chi_1(\alpha), \ldots, \chi_r(\alpha) \leq 1$ by (34), and deduce from (39) that

$$\max_{1 \leq i \leq r} |p_i(\omega_n a_n a k_n)| \leq C. \quad \square$$

We now use Proposition 5.9 with $\mathcal{S} = \overline{\mathcal{S}}_W$. This concludes the proof of Theorem 5.16.

6. **Weak adelic Mumford-Tate hypothesis and Lower bounds on Galois orbits.**

This section is central to the proof of the André-Pink-Zannier conjecture under our assumptions (Theorem 1.2). In this section, we state a precise form of the “weak adelic Mumford-Tate hypothesis”.

We then translate lower and upper bounds on adelic orbits of Appendices B and C into estimates for sizes of the Galois orbits in terms of the height functions of §4 (when the Mumford-Tate hypothesis holds).

For simplicity we will in the sequel refer to the ‘Mumford-Tate hypothesis’ or simply ‘MT hypothesis’.

Finally we provide some natural functoriality properties of the Mumford-Tate hypothesis, which will be needed for the reduction steps in the proof of our main theorem.
6.1. The Mumford-Tate hypothesis. We start with a property applicable in more general situations.

Definition 6.1. Let $M$ be a linear algebraic group over $Q$, let $K_M$ be a compact open subgroup, and let $U \leq M(\mathbb{A}_f)$ be a compact subgroup.

We say that $U$ is MT in $M$ if the indices

$$[K_M \cap M(Q_p) : U \cap K_M \cap M(Q_p)]$$

are finite and and bounded as $p$ ranges through primes, where $M(Q_p) \leq M(\mathbb{A}_f)$ is understood as a factor subgroup of $M(\mathbb{A}_f)$.

Note that the definition does not depend on the choice of $K_M$, as any two compact open subgroups are commensurable. We may always enlarge $K_M$ so that it takes the product form $K_M = \prod_p K_p$ in which case the indices become

$$[K_p : U \cap K_p].$$

Likewise if $U' \leq M(\mathbb{A}_f)$ is a compact subgroup commensurable to $U$, then $U$ is MT in $M$ if and only if $U'$ is MT in $M$. Note (and this is very important) that the condition that $U$ is MT in $M$ does not imply that $U$ is open in $M(\mathbb{A}_f)$.

The following observation is an immediate consequence of the definition.

Lemma 6.2. In the Definition 6.1, let

$$U_p := U \cap K_M \cap M(Q_p)$$

and

$$U' = \prod_p U_p \leq \prod_p M(Q_p).$$

Then $U$ is MT in $M$ if and only if $U'$ is MT in $M$.

We specialise the above definition to the context of images of Galois representations.

Definition 6.3. Let $(G, X)$ be a Shimura datum, let $x_0 \in X$ and let $M$ be the Mumford-Tate group of $x_0$, let $\rho_{x_0}$ be a Galois representation for $x_0$ defined over a field $E$ in the sense of Definition 3.1, and let $U = \rho_{x_0}(\text{Gal}(\overline{E}/E)) \leq M(\mathbb{A}_f)$ be the image of $\rho_{x_0}$.

(1) We say that $x_0$ satisfies the MT hypothesis, if $U$ is MT in $M$.

(2) Let $K \leq G(\mathbb{A}_f)$ be a compact open subgroup, and $s_0 = [x_0, 1] \in \text{Sh}_K(G, X)$. We say that $s_0$ satisfies the MT hypothesis if $U$ is MT in $M$. 
6.2. Lower bounds for Galois orbits in terms of finite heights under the MT hypothesis. The following statement is an essential ingredient in the proof of the main theorem §7. We also believe it to be of independent interest.

**Theorem 6.4.** Let $M$ be a connected reductive group over $\mathbb{Q}$ and $U \leq M(\mathbb{A}_f)$ be a compact subgroup which is MT in $M$ in the sense of Def. 6.1. We use the notations of Def. 1.7.

(1) Let $\phi_0 : M \to GL(N)$ be a representation over $\mathbb{Q}$, and let $W$ be the $GL(N)$-conjugacy class of $\phi_0$. We consider an affine embedding $\iota : W \to \mathbb{A}_Q^N$ and the corresponding function $H_f : W(\mathbb{Q}_f) \to \mathbb{Z}_{\geq 1}$ defined by (16). Then, as $\phi$ ranges through $W(\mathbb{A}_f)$, we have

$$[\phi(U) : \phi(U) \cap GL(N, \hat{\mathbb{Z}})] \approx H_f(\phi).$$

(2) Let $\phi_0 : M \to G$ be a morphism of algebraic groups over $\mathbb{Q}$ and let $W$ be the $G$-conjugacy class of $\phi_0$. We consider an affine embedding $\iota : W \to \mathbb{A}_Q^N$ and the corresponding function $H_f : W(\mathbb{Q}_f) \to \mathbb{Z}_{\geq 1}$ defined by (16). We also consider an open compact subgroup $K \leq G(\mathbb{A}_f)$. Then, as $\phi$ ranges through $W(\mathbb{A}_f)$, we have

$$[\phi(U) : \phi(U) \cap K] \approx H_f(\phi).$$

Let us first reduce the second assertion to the first one.

**Proof.** We identify $G$ with its image by a faithful representation $G \to GL(N)$. We may replace $K$ by a commensurable group, and assume $K$ is a maximal compact subgroup of $G(\mathbb{A}_f)$. For any maximal compact subgroup $K'$ of $GL(N, \mathbb{A}_f)$ such that $K \leq K' \leq GL(N, \mathbb{A}_f)$, we then have

$$K = K' \cap G(\mathbb{A}_f).$$

We choose such a $K'$, and, possibly conjugating by an element of $GL(N, \mathbb{Q})$, we may assume $K' = GL(N, \hat{\mathbb{Z}})$.

Consider $\phi : M \to G$ in (44). From $\phi(U) \leq G(\mathbb{A}_f)$ and (45), we deduce

$$[\phi(U) : \phi(U) \cap K] = [\phi(U) : \phi(U) \cap K'] = [\phi(U) : \phi(U) \cap GL(N, \hat{\mathbb{Z}})].$$

We have identified the left hand side of (45) with the left hand side of (44).

It will be enough to identify the right hand sides. We will show that a Height function $H_f$ on the $GL(N)$-conjugacy class of $\phi$, when
restricted to the $G$-conjugacy class, is a Height function on this $G$-conjugacy class.

If $H_f : GL(N, \mathbb{A}_f) \cdot \phi \to \mathbb{Z}_{\geq 1}$ is associated to $\iota : GL(N) \cdot \phi \to \mathbb{A}_Q^N$, then its restriction to $GL(N, \mathbb{A}_f) \cdot \phi$ is associated to $\iota' : G \cdot \phi \to GL(N) \cdot \phi \to \mathbb{A}_Q^N$, provided $\iota'$ is a closed embedding.

It is equivalent to proving that $G \cdot \phi \subseteq GL(N, \mathbb{A}_f) \cdot \phi$ is Zariski closed.

To do this, we choose the map

$$\iota : GL(N) \cdot \phi \xrightarrow{\iota' \mapsto d\phi'} \text{Hom}(m, gl(N)).$$

Because $G$ and $GL(N)$ are Zariski connected, this map is injective. As $M$ is reductive, according to [45], the image of $G \cdot \phi$ is closed in $\text{Hom}(m, gl(N))$, and thus $G \cdot \phi \subseteq GL(N, \mathbb{A}_f) \cdot \phi$ is Zariski closed. □

We now reduce the first assertion to Cor. B.2 and Th. B.1 and B.4.

Proof. Writing $K = GL(N, \mathbb{Z})$ for short, we may rewrite the left hand-side of (43) as

$$[\phi(U) : \phi(U) \cap K] = [\phi(U) \cdot K / K] = [U / \phi(K)] = [U : \phi(K)].$$

Theorem C.1 implies $[\phi(U) : \phi(U) \cap K] \leq H_f(\phi)$. We now prove $H_f(\phi) \leq [\phi(U) : \phi(U) \cap K]$.

It is enough to obtain a lower bound after replacing $U$ by the smaller group $U'' \leq U$ as in Lem. 6.2: without loss of generality we may assume $U = U''$. We thus assume that $U = \prod_p U_p$ as in (42).

The left hand-side is the product of the $K_p = GL(N, \mathbb{Z}_p)$, hence we have

$$[\phi(U) : \phi(U) \cap K] = \prod_p [\phi(U_p) : \phi(U_p) \cap K_p].$$

We apply definition 6.1 for $K_M = M(\mathbb{Z}) = M(\mathbb{A}_f) \cap GL(d, \mathbb{Z})$: the upper bound $C = \sup_p[M(\mathbb{Z}_p) : U_p]$ is finite. Using (82) we have

$$[\phi(M(U_p)) : \phi(M(U_p)) \cap GL(N, \mathbb{Z}_p)] \geq \frac{H_p(d\phi)}{c \cdot C}. 

(46)$$

As in the proof of (77) of Theorem B.1, we can deduce

$$[\phi(U) : \phi(U) \cap GL(N, \mathbb{Z})] \geq \frac{1}{(c \cdot C)^{\omega(H_f(d\phi))}} \cdot H_f(d\phi). 

(47)$$

Arguing as in the proof of (78) and (79) of Corollary B.2, we obtain

$$H_{W, f}(\phi) \approx H_f(d\phi) \leq [\phi(U) : \phi(U) \cap GL(N, \mathbb{Z})]. 

(48)$$
6.3. Functoriality properties of the MT hypothesis. The following uses general properties of adelic topologies on algebraic groups. A good reference is [38].

**Lemma 6.5.** Let \( \phi : M \to G \) be a morphism of linear algebraic groups over \( \mathbb{Q} \), and let \( U \leq M(\mathbb{A}_f) \) be a compact subgroup.

1. If \( U \) is MT in \( M \) then \( \phi(U) \) is MT in \( \phi(M) \).
2. If \( \phi \) is an isogeny onto its image (i.e., \( \ker(\phi) \) is finite), then \( U \) is MT in \( M \) if \( \phi(U) \) is MT in \( \phi(M) \).
3. We assume \( M \) is reductive. Let \( \text{ad}_M : M \to M^{ad} = M/Z_M(M) \) be the adjoint map, and \( \text{ab}_M : M \to M^{ab} = M/[M,M] \) be the abelianisation map. Then \( U \) is MT in \( M \) if and only if: \( \text{ad}_M(U) \) is MT in \( M^{ad} \) and \( \text{ab}_M(U) \) is MT in \( M^{ab} \).

The proof of Lemma 6.5 will rely on the following.

**Theorem 6.6.** Let \( \phi : H \to G \) be an epimorphism of \( \mathbb{Q} \)-algebraic groups and \( C \) be the number of components of \( \ker(\phi) \) for the Zariski topology.

1. Let \( K \leq H(\mathbb{A}_f) \) and \( K' \leq G(\mathbb{A}_f) \) be compact open subgroups of the form \( \prod_p K_p \) and \( \prod_p K'_p \). Then
   \[
   \forall p \gg 0, \phi(K_p) \leq K'_p \text{ and } [K'_p : \phi(K_p)] \leq C.
   \]
2. If \( C = 1 \) then the map \( p : H(\mathbb{A}_f) \to G(\mathbb{A}_f) \) is open: for any open subgroup \( K \leq H(\mathbb{A}_f) \), the image \( \phi(K) \) is open in \( G(\mathbb{A}_f) \).

The second assertion, which is [38, p.296, §6.2, Prop. 6.5], is a corollary of the first assertion. The first assertion follows from [38, p.,296, §6.2, Prop. 6.4] and [38, p.296, §6.2, Prop. 6.5] (using their exact sequence (6.9.) under conditions of their Lemma 6.6.).

Let us prove 1 of Lemma 6.5.

**Proof.** We choose a maximal compact subgroup \( K_M \leq M(\mathbb{A}_f) \), and a maximal compact subgroup \( K' \leq \phi(M)(\mathbb{A}_f) \) containing \( \phi(K_M) \). By maximality, they have a product form \( K_M = \prod_p K_p \) and \( K' = \prod_p K'_p \). According to Definition 6.1, there exists \( c \in \mathbb{R}_{>0} \) such that for all primes \( p \), we have \( c \geq [K_p : U_p \cap K_p] \). Applying \( \phi \) we deduce

\[
c \geq [\phi(K_p) : \phi(U_p \cap K_p)] = [\phi(K_p) : \phi(U_p) \cap \phi(K_p)].
\]

Let \( C \in \mathbb{R}_{>0} \) be given by Th. 6.6. Using natural inclusions \( \phi(U_p) \subseteq \phi(U)_p \) and \( \phi(K_p) \subseteq K'_p \), we have

\[
[K'_p : \phi(U)_p \cap K'_p] \leq [K'_p : \phi(U_p) \cap \phi(K_p)]
= [K'_p : \phi(K_p)] : [\phi(K_p) : \phi(U_p) \cap \phi(K_p)] \leq C \cdot [\phi(K_p) : \phi(U_p) \cap \phi(K_p)].
\]
Thus, for every prime \( p \), we have \([K'_p : \phi(U)_p \cap K'_p] \leq c \cdot C.\) \(\square\)

We now prove 2 of Lemma 6.5.

**Proof.** We write \( K_M = \prod K_p \) and \( K' = \prod K'_p \) as before.

We choose a set of generators \( \phi(u_1), \ldots, \phi(u_k) \) for \( \phi(U)_p \) and let \( U' \leq U \) be the compact subgroup topologically generated by the \( u_i \). Let us prove that \( k \) can be chosen independently of \( p \).

**Proof.** For a fixed \( p \) we use 1 of Lem. 6.8 with \( V = \phi(U)_p \). For large \( p \), the group \( V' := \exp(p\phi(m_{Z_p})) \) and the reduction map \( M(Z_p) \to M(F_p) \) are well defined and, by 3 of Lem. 6.8, we have \( V' \leq V \leq M(Z_p) \).

Applying the remark from the proof of Prof. 6.7 to the exact sequence \( 1 \to V' \to V \to M(F_p) \), it follows from Prop. 6.7 for the image of \( V \) and 2 of Lem. 6.8 for \( V' \).

Let \( F \) be the kernel of \( \phi \). This is a finite algebraic group by hypothesis. We define \( U'_p = U' \cap M(Q_p) \). Then \( U'_p \) is also the kernel of the map

\[
U' \ni \phi^{-1} (\phi(M(A_f))) \phi^{-1} (\phi(M(Q_p)))
\]

\[
\to \phi^{-1} (\phi(M(Q_p))) / M(Q_p) \xrightarrow{\sim} F(A_f)/(F \cap M)(Q_p).
\]

The last group is a commutative group isomorphic to a subgroup of \( (Z/(C))^{\infty} \) where \( C = |F(\overline{Q})| \). Because \( U' \) is generated by \( k \) elements, the size of the image of \( U' \) is bounded by \( C^k \).

We deduce

\[
[\phi(U)_p : \phi(U_p)] \leq [\phi(U') : \phi(U_p)]
\]

\[
\leq [\phi(U') : \phi(U_p')] \leq [U' : U'_p] \leq C^k. \quad \square
\]

**Proposition 6.7.** For all \( N \in \mathbb{Z}_{\geq 0} \) there exists \( k = k(N) \) such that for every prime \( p \) and every subgroup \( \hat{U} \leq GL(N, F_p) \), there exist \( u_1, \ldots, u_k \) in \( U \) which generate \( U \).

**Proof.** We fix \( N \). There exists \( p(N) \) such that \( p \geq p(N) \), so that we can apply Nori theory [51].

For \( p \leq p(N) \) we have \( \#U \leq \#GL(N, F_p) \leq p(N)^{N^2} \) and we take \( k(N) = p(N)^{N^2} \).

We assume that \( p \geq p(N) \) and apply Nori theory [51].

According to Jordan theorem [51, Th. C] there exist normal subgroups \( U^+ \leq U' \leq U \) with \( U^+ \) generated by the unipotent elements of \( U \), and \( U'/U^+ \) abelian of order prime to \( p \), and \( [U : U'] \leq d(N) \).

According to [51], there exists \( \hat{U} \leq GL(N)_p \) such that \( \hat{U}(F_p)^+ = U^+ \).
Define $U'' = \tilde{U}(\mathbb{F}_p) \cap U$. Moreover, one knows that there exists an injective morphism $U'/U'' \hookrightarrow GL(N', \mathbb{F}_p)$, where $N'$ is bounded in terms of $N$.

We will use the following remark. For every exact sequence $1 \to K \to G \to Q \to 1$, if $K$ and $Q$ are generated by $k_N$ and $k_Q$ elements, then $G$ is generated by $k_K + k_Q$ elements. Thus, in order to bound the size of a generating subset of $G$, it suffices to do it for $K$ and for $Q$.

Using the remark, it will be enough to prove that $U/U'$, $U'/U''$, $U''/U^+$ and $U^+$ can be generated by $k_1(N), k_2(N), k_3(N), k_4(N)$ elements. Then the proposition will be satisfied with $k(N) = \max\{k_1(N) + k_2(N) + k_3(N) + k_4(N); p(N)^N\}$.

As $\#U/U' \leq d(N)$, we can take $k_1(N) = d(N)$.

As $\tilde{U}$ is generated by unipotent subgroups, we can write $\tilde{U} = \tilde{S} \cdot \tilde{N}$ where $\tilde{S}$ is semisimple and $\tilde{N}$ is the unipotent radical. According to [51, Rem. 3.6, 3.6(v)], we have $\tilde{S}(\mathbb{F}_p)/\tilde{S}(\mathbb{F}_p)^+ \leq 2^N$. We deduce that $\#U''/U^+ \leq \#U(\mathbb{F}_p)/U(\mathbb{F}_p)^+ = \#S(\mathbb{F}_p)/S(\mathbb{F}_p)^+ \leq 2^N$.

We can thus take $k_2(N) = 2^N$.

The factor $U'/U''$ is isomorphic to an abelian subgroup of $GL(N', \mathbb{F}_p)$ of order prime to $p$. It is thus diagonalisable over some extension $\mathbb{F}_q$. Because $\mathbb{F}_q^\times$ is cyclic, every subgroup of $(\mathbb{F}_q^\times)^{N'}$ is generated by at most $N'$ elements.

We can thus take $k_3(N) = N'$.

Let $\tilde{U} \geq GL(N)_{\mathbb{F}_p}$ be the algebraic group associated to $U$ and let $\tilde{u} \leq \mathfrak{gl}(N, \mathbb{F}_p)$ be its Lie algebra. By [51], $\tilde{u} \leq \mathfrak{gl}(N, \mathbb{F}_p)$ is linearly generated by nilpotents. Let $X_1, \ldots, X_d$, with $d \leq N^2$ be a linear basis of nilpotent elements. Denote by $U' = \langle \exp(X_1), \ldots, \exp(X_d) \rangle$ the group generated by their exponentials, and consider the associated $\tilde{u}' \leq \tilde{u}$ and $\tilde{U}' \leq \tilde{U}$. We have $X_1, \ldots, X_d \in \tilde{u}'$. Thus $\tilde{u}' = \tilde{u}$ and $\tilde{U}' = \tilde{U}$. From [51, Th. B], we get $U = U^+ = \tilde{U}(\mathbb{F}_p)^+ = \tilde{U}'(\mathbb{F}_p)^+ = U^+ = U'$.

Thus $U$ is generated by at most $N^2$ elements $\exp(X_1), \ldots, \exp(X_d)$.

We can thus take $k_4(N) = N^2$.

We used the following.

**Lemma 6.8.** Let $M \leq GL(N)$ be an algebraic subgroup defined over $\mathbb{Q}_p$ and let $\mathfrak{m} \leq \mathfrak{gl}(N, \mathbb{Q}_p)$ be its Lie algebra.

1. Let $V \leq GL(N, \mathbb{Z}_p)$ a compact subgroup. Then $V$ is topologically finitely generated.
2. Then $V' := \exp(\mathfrak{m} \cap 2p\mathfrak{gl}(N, \mathbb{Z}_p))$ is topologically generated by at most $N^2$ elements if $p$ is large enough.
3. Let $M(\mathbb{Z}_p) := M(\mathbb{Q}_p) \cap GL(N, \mathbb{Z}_p)$ and $V \leq M(\mathbb{Z}_p)$ an open subgroup such that $C := [M(\mathbb{Z}_p) : V] \in \mathbb{Z}_{\geq 1}$. Then for $p > C$,
we have
\[ V' \leq V. \]

**Proof.** The first assertion is [50, Prop. 2].

Let \( G = \exp(2p\mathfrak{gl}(N, \mathbb{Z}_p)) = 1 + 2p\mathfrak{gl}(N, \mathbb{Z}_p) \) and \( H = V' \leq G \).

According to [14, Th. 5.2] the pro-\( p \) group is powerful and \( d(G) = N^2 \).

We can thus apply [14, Th. 2.9]. This proves the second assertion.

As \( G \) is a pro-\( p \) group, by [38, Lem 4.8, p. 138], \( V' \) is a pro-\( p \) group.

We also have
\[ [V' : V' \cap V] \leq [M(\mathbb{Z}_p) : V] = C. \]

Assume \( p > C \) and assume by contradiction that there exists \( w \in V' \setminus V \). We denote by \( w^\mathbb{Z} \) the subgroup generated by \( w \). Then \( c := [w^\mathbb{Z} : w^\mathbb{Z} \cap V] \neq 1 \) and \( c \leq C \). But \( c \) is a power of \( p \) because \( V' \) is a pro-\( p \) group: thus \( c \geq p \). We deduce that \( C \geq c \geq p \). This contradicts our assumptions. \( \square \)

We prove 3 of Lemma 6.5. We will make use of Goursat’s Lemma.

**Proof.** As \( M \) is reductive, the map \((ad_M, ab_M) : M \rightarrow M' := M^\text{ad} \times M^\text{ab}\) is an isogeny. From (2) of Lemma 6.5 it follows that it is enough to prove that the image \( V \) of \( U \) in \( M'(\mathbb{A}_f) \) is MT in \( M' \). We may thus assume \( M = M^\text{ad} \times M^\text{ab} \).

Using Lemma 6.2 we may assume \( U = \prod_p U_p \). Let
\[ K_M = \prod K_{M,p} = \prod K_{M^\text{ad,p}} \times K_{M^\text{ab,p}} \leq M(\mathbb{A}_f) \]
be a maximal compact subgroup containing \( U \).

By assumption there is an upper bound \( C \in \mathbb{Z}_{\geq 1} \) for \([K_{M^\text{ab,p}} : ab_M(U_p)] \) and \([K_{M^\text{ad,p}} : ad_M(U_p)]\), independent of \( p \).

Let \( H_1 = ad_M(U_p) \) and \( H_2 = ab_M(U_p) \) and \( \Gamma = (ad_M, ab_M)(U_p) \leq H_1 \times H_2 \). Let \( N_1 = \Gamma \cap H_1 \) and \( N_2 = \Gamma \cap H_2 \). By Goursat’s Lemma, \( N_1 \) and \( N_2 \) are normal subgroups in \( H_1 \) and \( H_2 \) and there is an isomorphism (whose graph is \( \Gamma/(N_1 \times N_2) \))
\[ (52) \quad H_1/N_1 \overset{\sim}{\rightarrow} H_2/N_2. \]

Because \( H_2 \) is abelian, \( N_1 \) contains the derived subgroup \([H_1, H_1] \).

By the first part of Lemma 6.9, \([H_1 : N_1] \) is finite for every prime \( p \), and by the second part of Lemma 6.9, \([H_1 : N_1] \) is bounded by \( C(M^\text{ad}) \) for almost every prime \( p \).

As a result there exists \( C' \in \mathbb{Z}_{\geq 1} \) such that \([H_1 : N_1] \leq C' \) for every prime \( p \). Using (52), we also have \([H_2 : N_2] \leq C' \) for every prime \( p \).

Recall that \( N_1 \times N_2 \leq \Gamma \). It follows
\[ [H_1 \times H_2 : \Gamma] \leq [H_1 : N_1] \cdot [H_2 : N_2] = C'^2. \]
By definition of $C$, 
$$[K_{M,p} : H_1 \times H_2] \leq C^2.$$ 
We deduce 
$$[K_{M,p} : (ad_M, ab_M)(U_p)] = [K_p : H_1 \times H_2] \cdot [H_1 \times H_2 : \Gamma] \leq C^2C''^2.$$ 
The bound is independent of $p$, which concludes. ---

**Lemma 6.9.** Let $G$ be a semisimple algebraic group over $\mathbb{Q}$, and for every prime $p$, let $U_p, K_p \leq G(\mathbb{Q}_p)$ be compact open subgroups such that $K = \prod_p K_p \leq G(\mathbb{A}_F)$ is open. Let $[U_p, U_p]$ be the subgroup generated by commutators.

1. For every prime $p$, the quotient $U_p/[U_p, U_p]$ is finite.
2. There exists $C(G) \in \mathbb{Z}_{\geq 1}$ such that, for almost all $p$, if $[K_p : U_p \cap K_p] < p$ then $U_p/[U_p, U_p] < C(G)$.

**Proof.** The first assertion follows from the fact that $[U_p, U_p]$ is open, because $G$ is semisimple.

We prove the second assertion. We may replace $U_p$ by $K_p \cap U_p$ and assume $U_p = K_p \cap U_p \leq K_p$. Thus $[K_p : K_p \cap U_p] = [K_p : U_p] < p$.

Let us identify $G$ with its image by a faithful linear representation $G \rightarrow GL(N)$. For $p$ large enough, we have $K_p = G(\mathbb{Z}_p) := G(\mathbb{Q}_p) \cap GL(N, \mathbb{Z}_p)$.

Let $G(\mathbb{Z}_p)^+$ and $G(\mathbb{F}_p)^+$ be as in Lemma 6.10 below.

Then $U_p \cap G(\mathbb{Z}_p)^+$ is an open subgroup of $G(\mathbb{Z}_p)^+$ and,
$$[G(\mathbb{Z}_p)^+ : U_p \cap G(\mathbb{Z}_p)^+] \leq [G(\mathbb{Z}_p) : U_p] < p.$$ (Recall the assumption $[K_p : U_p] < p$.)

As $G(\mathbb{Z}_p)^+$ is generated by pro-$p$-groups, we have, for every subgroup $L \leq G(\mathbb{Z}_p)^+$, 
$$[G(\mathbb{Z}_p)^+ : L] > 1 \Rightarrow [G(\mathbb{Z}_p)^+ : L] \geq p.$$ 
Therefore, with $L = U_p$, 
$$[G(\mathbb{Z}_p)^+ : U_p \cap G(\mathbb{Z}_p)^+] = 1.$$ 
At the level of derived subgroups, we have 
$$[G(\mathbb{Z}_p)^+ : G(\mathbb{Z}_p)^+] \subseteq [U_p, U_p].$$ 

We deduce 
$$[G(\mathbb{Z}_p) : [U_p, U_p]] \leq [G(\mathbb{Z}_p) : G(\mathbb{Z}_p)^+] \cdot [G(\mathbb{Z}_p)^+ : [G(\mathbb{Z}_p)^+, G(\mathbb{Z}_p)^+]].$$ 

We note that $G(\mathbb{Z}_p)^+ \leq G(\mathbb{Z}_p)$ is an open subgroup of index prime to $p$. It follows that the image of $G(\mathbb{Z}_p)^+$ in $G(\mathbb{F}_p)$ contains $G(\mathbb{F}_p)^+$. Thus 
$$[G(\mathbb{Z}_p) : G(\mathbb{Z}_p)^+] \leq [G(\mathbb{F}_p) : G(\mathbb{F}_p)^+].$$
We have, by [32, p. 270],

\[(53) \quad [G(\mathbb{F}_p) : G(\mathbb{F}_p)^+] \leq 2^N.\]

For \(p\) large enough:

- We have \(G(\mathbb{F}_p) = \tilde{G}(\mathbb{F}_p)\) for a connected semisimple \(\mathbb{F}_p\)-algebraic subgroup \(\tilde{G} \leq GL(N)_{\mathbb{F}_p}\);
- We have \([G(\mathbb{F}_p)^+, G(\mathbb{F}_p)^+] = [\tilde{G}, \tilde{G}]_{\mathbb{F}_p} = \tilde{G}(\mathbb{F}_p)^+\), using [51].

Thus \([G(\mathbb{Z}_p)^+, G(\mathbb{Z}_p)^+]\) maps surjectively onto

\([G(\mathbb{F}_p)^+, G(\mathbb{F}_p)^+] = G(\mathbb{F}_p)^+.\]

We apply Lemma 6.10 to \(H = [G(\mathbb{Z}_p)^+, G(\mathbb{Z}_p)^+]\). We deduce

\([G(\mathbb{Z}_p)^+, G(\mathbb{Z}_p)^+] = G(\mathbb{Z}_p)^+.\]

This implies

\[(54) \quad [G(\mathbb{Z}_p)^+: [G(\mathbb{Z}_p)^+, G(\mathbb{Z}_p)^+]] = 1.\]

The second assertion of Lemma 6.9 follows from (53) and (54). \(\square\)

**Lemma 6.10** ([7, Fact 2.4 and its proof]). Let \(G \leq GL(N)_{\mathbb{Q}}\) be a connected semisimple algebraic subgroup. For every prime \(p\), define \(G(\mathbb{Z}_p) := G(\mathbb{Q}_p) \cap GL(N, \mathbb{Z}_p)\) and denote by \(G(\mathbb{F}_p)\) the image of \(G(\mathbb{Z}_p)\) in \(GL(N, \mathbb{F}_p)\). We denote by \(G(\mathbb{F}_p)^+ \leq G(\mathbb{F}_p)\) and \(G(\mathbb{Z}_p)^+ \leq G(\mathbb{Z}_p)^+\) the subgroups generated by \(p\)-Sylow subgroups, resp. \(pro-p\)-Sylow.

Then, for \(p\) large enough: if \(H \leq G(\mathbb{Z}_p)^+\) maps surjectively onto \(G(\mathbb{F}_p)^+\), then \(H = G(\mathbb{Z}_p)^+\).

### 6.4. MT hypothesis for Images of Galois representations.

We use the notations of Def. 6.3. We assume furthermore that \(E\) is of finite type over \(\mathbb{Q}\). In this case we have the following.

**Lemma 6.11.** If \(x_0\) is a special point (i.e., \(M = M^{ab}\)), then \(x_0\) satisfies the MT hypothesis.

The Galois representation \(Gal(\overline{E}/E) \rightarrow M^{ab}(\mathbb{A}_f)\) is prescribed by Deligne-Shimura reciprocity law, which is part of the definition of a Canonical model [13, 2.2.5]. In this case, we know that \(M = M^{ab}\) is the Zariski closure of the image of \(x_0\). It follows that the morphism [13, 2.2.2.1] is an epimorphism, and we can apply Th. 6.6.\(^{14}\)

\(^{14}\)If the kernel of \(\mu_h : GL(1)_E \rightarrow T_E\) is connected, then the Galois image is actually open for the topology induced by the adelic topology on \(T(\mathbb{A}_f)\). This is also the \(H\)-maximality condition. See [8].
The following is not needed but can help relate our MT hypothesis to other notions found in literature.

**Theorem 6.13.** Assume $M$ is a semisimple and simply connected algebraic group over $\mathbb{Q}$. Then a subgroup $U \leq M(\mathbb{A}_f)$ is MT in $M$ if and only if it is an open subgroup.

This relies on strong approximation, Hasse principle and Kneser-Tits properties for $M$. See [12] for related discussions.

6.4.1. For moduli spaces of abelian varieties or more generally for Shimura varieties of abelian type, a Galois representation associated to a point $x_0 \in X$ can be deduced from the Galois representation on the Tate module of an abelian variety.

We have the following.

**Theorem 6.14** ([8, Th. A(i)] [22, Th. 10.1]). Let $S$ be a Shimura variety of Hodge type, let $s \in S$ be a point.

If the abelian variety $A$ associated to $s$ satisfies the classical Mumford-Tate conjecture at some prime $\ell$, then $s$ satisfies the weakly adelic Mumford-Tate hypothesis.

Using Lemma 6.12 we can deduce

**Theorem 6.15.** Let $S$ be a Shimura variety of abelian type, let $s \in S$ be a point.

If $s$ satisfies the Mumford-Tate conjecture at some prime $\ell$ in the sense of [53], then $s$ satisfies the weakly adelic Mumford-Tate hypothesis.

6.4.2. As observed in [2], the combination of a theorem of Deligne-André and with a theorem of Weisfeiler [29] and Nori [32] produces, in any Shimura variety, many examples of (non algebraic) points for which the MT hypothesis is satisfied. With our terminology it is stated as follows.

**Theorem 6.16** ([2, Th.1.2]). Let $M$ be the Mumford-Tate group of a point $x_0 \in X$ for a Shimura datum $(G, X)$. We decompose the adjoint datum $(M^{ad}, X_{M^{ad}})$ of $(M, X_M) := (M, M(\mathbb{R}) \cdot x_0)$ as a product

$$(p_1, \ldots, p_f) : (M^{ad}, X_{M^{ad}}) \cong (M_1, X_1) \times \cdots \times (M_f, X_f)$$

with respect to the $\mathbb{Q}$-simple factors $M_i$ of $M^{ad}$.

Assume that for some compact open subgroups $K_i \leq M_i(\mathbb{A}_f)$

$\forall i \in \{1; \ldots; f\}$, $[p_i \circ ad_M(x_0)] \in Sh_{K_i}(M_i, X_i)(\mathbb{C}) \setminus Sh_{K_i}(M_i, X_i)(\overline{\mathbb{Q}})$.

Then $x_0$ satisfies the MT hypothesis.
7. Proof of the main result

In this section we prove the Theorem 1.2, following the strategy outlined in §1.4. We then give in §7.3 a variant of Pila-Wilkie Theorem.

7.1. Reduction steps. We put ourselves in the situation of Theorem 1.2 and Conjecture 1.1.

Let $Z$ be an irreducible component of $\Sigma^{\text{Zar}}$. The aim is to prove that $Z$ is weakly special. We may replace $\Sigma$ by $\mathcal{H}(x_0) \cap Z$.

7.1.1. Reduction to the Hodge generic case. We will reduce the theorem to the case where $Z$ is Hodge generic in $\text{Sh}_K(G, X)$. For convenience we will assume that $s_0 = [x_0, 1] \in Z$. We choose a Hodge generic point $z$ in $Z$. One knows that one can choose a lift $\tilde{z}$ of $z$ in $X$ such that the Mumford-Tate group $G'$ of $\tilde{z}$ contains $M$. We write $X' = G'(\mathbb{R}) \cdot \tilde{z}$. We have a Shimura morphism

$$\Psi : \text{Sh}_{K \cap G'(\mathbb{A}_f)}(G', X') \rightarrow \text{Sh}_K(G, X).$$

(The smallest special subvariety of $\text{Sh}_K(G, X)$ containing $Z$ is the image of one component of $\text{Sh}_{K \cap G'(\mathbb{A}_f)}(G', X')$.) Let $Z'$ be the inverse image of $Z$ by $\Psi$. It is known that $Z$ is weakly special if and only if any component of $Z'$ is weakly special.

In the notations of Prop. 2.6, we have

$$\Sigma' := \tilde{\Psi}^{-1}(\Sigma) = \mathcal{H}'([x_0, 1]) \cap Z'.$$

Because $\text{Sh}_{K \cap G'(\mathbb{A}_f)}(G', X') \rightarrow \Psi(\text{Sh}_{K \cap G'(\mathbb{A}_f)}(G', X'))$ is flat, and because $Z$ is in the image of $\Psi$, we deduce that $\Sigma'$ is dense in $Z'$, and hence dense in every component of $Z'$.

Thus, in proving the conclusion of the theorem we may replace $Z$ by a component of $Z'$, and $(G, X)$ by $(G', X')$, and $K$ by $\mathcal{K} \cap G'(\mathbb{A}_f)$.

On the other hand, the Mumford-Tate hypothesis depends only on $M$, and thus is insensitive to such substitutions.

In other words, we can, and will, assume that $Z$ is Hodge generic in $\text{Sh}_K(G, X)$.

7.1.2. Reduction to the adjoint datum. We will reduce the theorem to the case where $G = G^{\text{ad}}$ is of adjoint type. Here we use geometric Hecke orbits.

Using Theorem 2.4, we write our generalised Hecke orbit

$$\mathcal{H}([x_0, 1]) = \mathcal{H}^a([x_0, 1]) \cup \ldots \cup \mathcal{H}^a([x_k, 1])$$

as a finite union of geometric Hecke orbits. We define accordingly

$$\Sigma_i = Z \cap \mathcal{H}^a([x_i, 1]).$$
As \( Z \) is irreducible there is at least one \( i \in \{0, \ldots, k\} \) such that \( \Sigma_i \) is Zariski dense in \( Z \).

Because the Galois representations \( \rho_{x_1}, \ldots, \rho_{x_k} \) of \( x_1, \ldots, x_k \) can be deduced from \( \rho_{x_0} \) using § 3, the Mumford-Tate hypothesis will still be valid even if we replace \( x_0 \) by \( x_i \). We assume for simplicity that \( x_i = x_0 \).

We choose an open compact subgroup \( K' \leq G^{ad}(\mathbb{A}_f) \) so that we can consider the Shimura morphism
\[
\Psi : Sh_K(G, X) \rightarrow Sh_{K'}(G^{ad}, X^{ad}).
\]

Let \( Z' \) be the image of \( Z \). One knows that \( Z \) is weakly special in \( Sh_K(G, X) \) if and only if \( Z' \) is weakly special in \( Sh_{K'}(G^{ad}, X^{ad}) \).

Then \( \Psi(\Sigma_0) \) is dense in \( Z' \). Denote \( x_0^{ad} \) the image of \( x_0 \) in \( X^{ad} \), and define
\[
\Sigma' := H^0([x_0^{ad}, 1]).
\]

Using § 2.2.3, we get
\[
\Psi(\Sigma_0) \subset \Sigma' \subset Z'
\]
and thus \( \Sigma' \) is Zariski dense in \( Z' \).

Let \( M' \) be the image of \( M \) by \( ad_G : G \rightarrow G^{ad} \). Then \( M^{ad} \simeq M'^{ad} \) because \( \ker(ad_G) \) is commutative and central in \( G \). In view of § 6, the Mumford-Tate hypothesis will still hold for \( x_0^{ad} \in X^{ad} \).

Thus, we can, and will, assume \( G = G^{ad} \).

7.1.3. Induction argument for factorisable subvarieties. The following reduction will be useful at the very end of the whole proof.

We recall that \( G \) is a direct product \( G_1 \times \ldots \times G_f \) of its \( \mathbb{Q} \)-simple subgroups.

It can be easily proved that in the Theorem 1.2 we can replace \( K \) by any other compact open subgroup. After possibly replacing \( K \) by the open subgroup \( \prod_{i=1}^f K_i := \prod_{i=1}^f K \cap G_i(\mathbb{A}_f) \), there are factorisations
\[
X = \prod_{i=1}^f X_i
\]
and
\[
Sh_K(G, X) = \prod_{i=1}^f Sh_{K_i}(G_i, X_i).
\]

The factorisation (55) is defined over the reflex field \( E(G, X) \), hence over \( E \). Consider a nontrivial partition \( \{1; \ldots; f\} = I \cup J \) and the corresponding nontrivial factorisation of Shimura data
\[
(G, X) \xrightarrow{(\rho_I, \rho_J)} (G_I, X_I) \times (G_J, X_J)
\]
with
\[
(G_I, X_I) = \prod_{i \in I} (G_i, X_i) \text{ and } (G_J, X_J) = \prod_{i \in J} (G_j, X_j).
\]
By functoriality §3.2 for $\phi = p_I \circ \phi_0$ (resp. $\phi = p_J \circ \phi_0$), we will have
\[
\rho_{p_I(x_0)} = p_I \circ \rho_{x_0} \quad \text{and} \quad \rho_{p_J(x_0)} = p_J \circ \rho_{x_0}.
\]
As explained in § 6, the Mumford-Tate hypothesis will hold for $p_I(x_0)$ and for $p_J(x_0)$.

Suppose that $Z$ factors as a Cartesian product
\[
Z_I \times Z_J \subseteq Sh_{K_I}(G_I, X_I) \times Sh_{K_J}(G_J, X_J)
\]
in the corresponding factorisation of Shimura varieties. From §2.2.2, we have
\[
\mathcal{H}^g(x_0) = \mathcal{H}^g(p_I(x_0)) \times \mathcal{H}^g(p_J(x_0))
\]
and
\[
\mathcal{H}^g([x_0, 1]) = \mathcal{H}^g([p_I(x_0, 1])] \times \mathcal{H}^g([p_J(x_0), 1])
\]
Recall that the partition $\{1; \ldots; f\} = I \cup J$ is not trivial. Arguing by induction on $f$, we can assume that the Theorem 1.2 proven for $Z_I$ and $Z_J$. Then $Z_I \times Z_J$ is also a weakly special subvariety and we are done.

Henceforth we assume that for every non trivial partition $\{1; \ldots; f\} = I \cup J$, the variety $Z$ is not a product of the form (56).

7.2. Central arguments. Let us recollect some of the notations and notions we will be using.

We have an irreducible subvariety $Z$ of $Sh_K(G, X)$ containing a Zariski dense subset $\Sigma$ contained in the generalised Hecke orbit $\mathcal{H}([x_0, 1])$ of the point $[x_0, 1]$. Let $E$ be a field of finite type over $\mathbb{Q}$ such that $Z$ and $[x_0, 1]$ are defined over $E$, and passing to a finite extension we have a Galois representation $\rho : \text{Gal}(\overline{E}/E) \rightarrow M(A_f) \cap K$ as in Def. 3.1 and our main hypothesis is that its image $U := \rho(\text{Gal}(\overline{E}/E))$ satisfies Def. 6.3. Passing to a finite extension we also assume that $E$ is a field of definition for every geometric component of $Sh_K(G, X)$.

We reduce the Theorem 1.2 to the case where $\Sigma$ is contained in a single geometric Hecke orbit. According to Th. 2.4 the generalised Hecke orbit is a finite union of geometric orbit,
\[
\mathcal{H}([x_0, 1]) = \mathcal{H}^g([x_0, 1]) \cup \mathcal{H}^g([\phi_I \circ x_0, 1]) \cup \ldots \cup \mathcal{H}^g([\phi_k \circ x_0, 1]).
\]
As $Z$ is irreducible, at least one of the intersections $Z \cap \mathcal{H}^g([\phi_I \circ x_0, 1])$ is Zariski dense in $Z$. From §3.2, we obtain $\rho_{\phi_I \circ x_0} = \phi_I \circ \rho_{x_0}$ and the MT Hypothesis is still valid for $\phi(U)$ in $\phi(M) = M_{\phi_I \circ x_0}$. Without loss of generality may assume $\phi_I = \phi_0$, that is $\phi_I \circ x_0 = x_0$.

We may also assume that $[x_0, 1] \in Z$ and thus that $Z$ is contained in the image of $X \times \{1\}$ in $Sh_K(G, X)$.
7.2.1. Covering by Siegel sets. We choose a minimal $\mathbb{Q}$-parabolic subgroup $P$ of $G$ and a maximal compact subgroup $K_\infty$ of $G(\mathbb{R})^+$, for instance $K_{x_0} = Z_{G(\mathbb{R})}(x_0)$. We define

$$X^+ = G(\mathbb{R})^+ \cdot x_0 \subset X$$

and denote by

$$S^+ \subset Sh_K(G, X)$$

the geometric component of $Sh_K(G, X)$ which is the image of $X^+ \times \{1\}$.

See Def. 5.10 for the definition of a Siegel set associated to $P$ and $K_\infty$.

It is known that there is a finite set $\{g_1; \ldots; g_c\} \subseteq G(\mathbb{Q})$ and Siegel sets $\mathcal{S}_1, \ldots, \mathcal{S}_c$ associated to $g_1, \ldots, g_c$ and $K_\infty$ such that $S^+$ is the image of $\mathcal{S} := \mathcal{S}_1 \cup \ldots \cup \mathcal{S}_c$.

For each $\mathcal{S}_i$, it is assumed that $\Omega$ from Def. 5.10 is a bounded semi-algebraic subset.

Let $\mathcal{S}_W = \mathcal{S}/Z_{G(\mathbb{R})}(M)$ be the image of $\mathcal{S}$ in $W^+(\mathbb{R})$.

The maps

$$G(\mathbb{R}) \xrightarrow{g \rightarrow gZ_{G(\mathbb{R})}(M)} G(\mathbb{R})/Z_{G(\mathbb{R})}(M) \xrightarrow{gZ_{G(\mathbb{R})}(M) \rightarrow gK_\infty} X = G(\mathbb{R})/K_\infty$$

are real algebraic and thus semi-algebraic. It follows that $\mathcal{S}_W$ is semi-algebraic, that its image $\mathcal{S}_X$ in $X$ is semi-algebraic and that the map

$$(58) \quad p_{W,X} : \mathcal{S}_W \rightarrow \mathcal{S}_X$$

is semi-algebraic.

7.2.2. O-minimality. We use the theory of o-minimal structures and recall that the map

$$\pi_{\mathcal{S},X} : \mathcal{S}_X \rightarrow S^+$$

is definable in the o-minimal structure $\mathbb{R}_{an,\exp}$ by [25]. As (58) is semi-algebraic, it is definable in $\mathbb{R}_{an,\exp}$, and the following is definable in $\mathbb{R}_{an,\exp}$ as well

$$\pi_{\mathcal{S},W} := p_{W,X} \circ \pi_{\mathcal{S},X} : \mathcal{S}_W \rightarrow \mathcal{S}_X \rightarrow S^+.$$ 

The algebraic variety $Z$ is definable in $\mathbb{R}_{an,\exp}$ and its inverse image

$$\tilde{Z}_W = \pi_{\mathcal{S},W}^{-1}(Z)$$

is definable in $\mathbb{R}_{an,\exp}$ as well.

Because $E$ is a field of definition for $Z$, for every $\sigma \in Gal(\overline{E}/E)$ and $z \in Z(\overline{E})$ we have $\sigma(z) \in Z$, and finally

$$Gal(\overline{E}/E) \cdot z \subset Z.$$ 

Assume now that $z$ also belongs to $\mathcal{H}^g(x_0)$. For every

$$z' \in Gal(\overline{E}/E) \cdot z$$
we have $z' \in Z \subset S^+$ and we can find $\phi_{z'} \in W(\mathbb{Q})$ such that
\[
\phi_{z'} = [\phi_{z'} \circ x_0, 1].
\]
Because $\mathcal{S}_X$ maps onto $S^+$ we may assume that $\phi_{z'} \circ x_0 \in \mathcal{S}_X$. Equivalently, we have
\[
\phi_{z'} \in \mathcal{S}_W.
\]
The set
\[
Q(z) = W(\mathbb{Q}) \cap \pi^{-1}_{\mathcal{S}_W} (Gal(\overline{E}/E) \cdot z)
\]
maps onto $Gal(\overline{E}/E) \cdot z$ and we deduce
\[
|Q(z)| \geq |Gal(\overline{E}/E) \cdot z|.
\]

7.2.3. Height bounds. We consider the affine embedding $\iota : W \to A_{\dim(M) \cdot \dim(G)}$ of §4.3. Let $H_W$ and $H_f$ be as in (17).

We can of course assume that $Z$ is infinite, and because
\[
\Sigma := Z \cap H^p(x_0)
\]
is Zariski dense, it is infinite as well, and we can choose an infinite sequence $(z_n)_{n \in \mathbb{Z}_{\geq 1}}$ of pairwise distinct $z_n \in \Sigma$. We also assume that this sequence is Zariski generic in $Z$.

By hypothesis, Def. 6.1 and 6.3 apply, and thus we invoke Th. 6.4 and, by Prop. 3.6, use it for Galois orbits. We have
\[
H_f(\phi) \preceq |Gal(\overline{E}/E) \cdot [\phi \circ x_0, 1]| \text{ on } W(\mathbb{Q}).
\]
Thanks to the height comparison Th. 5.16, we have
\[
H_W(\phi) \preceq H_f(\phi) \text{ on } W(\mathbb{Q}) \cap \mathcal{S}_W.
\]
It follows
\[
H_W(\phi) \preceq |Gal(\overline{E}/E) \cdot [\phi \circ x_0, 1]| \text{ on } W(\mathbb{Q}) \cap \mathcal{S}_W.
\]
More precisely, there are $a, b \in \mathbb{R}_{>0}$ such that
\[
\forall \phi \in W(\mathbb{Q}) \cap \mathcal{S}_W, a + H_W(\phi)^b \leq |Gal(\overline{E}/E) \cdot [\phi \circ x_0, 1]|.
\]
Using (59) we deduce
\[
a + H_W(\phi_{z_n})^b \leq |Q(z_n)|.
\]
From Prop. 4.3 we have
\[
\forall z' \in Gal(\overline{E}/E) \cdot z_n, H_f(\phi_{z'}) = H_f(\phi_{z_n})
\]
and because $H_f(\phi)$ only depends on $[\phi \circ x_0, 1]$ we have
\[
\forall \phi \in Q(z_n), H_f(\phi) = H_f(\phi_{z_n}).
\]
We make (60) precise by choosing $a', b'$ such that
\[
\forall \phi \in W(\mathbb{Q}) \cap \mathcal{S}_W, H_W(\phi) \leq a' + H_f(\phi)^b'.
\]
For $\phi \in Q(z_n) \subset W(\mathbb{Q}) \cap \mathcal{G}_W$ we get

$$H_W(\phi) \leq a' + H_f(\phi)^b' = a' + H_f(\phi_{z_n})^b'.$$

Writing $k(n) = H_f(\phi_{z_n})$, we deduce from the above that the subset $Q(z_n) \subseteq \tilde{Z} \cap W(\mathbb{Q})$ contains at least $a + k(n)^b$ points of $H_W$-height at most $a' + k(n)^{b'}$.

Because the $z_n$ are distinct, so are the inverse images $\phi_{z_n}$, and by Northcott theorem we deduce that $H_W(\phi_{z_n}) \to +\infty$, and thus $k(n) \to +\infty$.

We are ready to use the Pila-Wilkie theorem.

7.2.4. Pila-Wilkie theorem. We use the form Theorem 7.1 of the Pila-Wilkie theorem. We denote $K^{\mathbb{R}}_\infty$ the real algebraic group corresponding to $K_\infty$, and $X_{\mathbb{R}}$ the algebraic variety $G_{\mathbb{R}}/K^{\mathbb{R}}_\infty$ over $\mathbb{R}$ (we have $X \subset X_{\mathbb{R}}(\mathbb{R})$). We apply Theorem 7.1 to the morphism $p : W = G_{\mathbb{R}}/Z_{G_{\mathbb{R}}}(M) \to X_{\mathbb{R}} = G_{\mathbb{R}}/K^{\mathbb{R}}_\infty$ and the definable subset

$$\tilde{Z}_X := \pi_{E, X}^{-1}(Z) \subset X \subset X_{\mathbb{R}}(\mathbb{R}).$$

We deduce for every $n$ that

$$|Q(z_n) \cap (\tilde{Z}_X \setminus \tilde{Z}_X^{alg})| = (a' + H_f(\phi_{z_n})^b')^{o(1)} = o(|Q(z_n)|).$$

Thus, for $n \gg 0$, we have

$$Q(z_n) \cap \tilde{Z}_X^{alg} \neq \emptyset.$$

In other terms, for almost every $n$, there exist $\phi \in Q(z_n)$, and a non-zero dimensional semialgebraic subset $A_n \subset \tilde{Z}_X$, such that $\phi \circ x_0 \in A_n$.

We will now use the Hyperbolic Ax-Lindemann-Weierstrass theorem.

7.2.5. Functional transcendance. According to Ax-Lindemann-Weierstrass theorem (see [25]), that for $n \gg 0$, there exists a weakly special subvariety $S'_n$ of $S^+$ such that

$$z'_n \in \pi_{E, X}(A_n) \subset S_n \subset Z.$$

One can check that a weakly special subvariety containing a $\overline{E}$-valued point is defined over $\overline{E}$. It follows that this $S'_n$ is defined over $\overline{E}$, and applying $\sigma \in Gal(\overline{E}/E)$ such that $\sigma(z'_n) = z_n$, the conjugated subvariety $S_n = \sigma(S'_n)$ will be: weakly special, contained in $\overline{Z}$ and containing $z_n$.

Because the sequence $z_n$ is generic in $Z$, the family $(S_n)_{n \geq 0}$ is Zariski dense in $Z$.

Because $A_n$ has non-zero semialgebraic dimension, and $\pi_{E, X}$ has finite fibers, the image $\pi_{E, X}(A_n)$ has non-zero semialgebraic dimension, and $S'_n$ has non-zero dimension as a variety, and $S_n$ also.
We are ready the so-called geometric part of André-Oort conjecture.

7.2.6. Geometric André-Oort. We reuse the notations of §7.1.3 From the Geometric part of André-Oort conjecture from [52, 40], there exists a partition \( \{1; \ldots; c\} = I \sqcup J \), with \( I \neq \emptyset \), but possibly \( J = \emptyset \), such that we have a factorisation

\[
Z = S_1 \times Z_J \subset Sh_{K_I}(G_I, X_I) \times Sh_{K_J}(G_J, X_J),
\]

where \( S_1 \) is a geometric component of \( Sh_{K_I}(G_I, X_I) \), and \( Z_J \) is a subvariety of \( Sh_{K_J}(G_J, X_J) \).

Because we assumed that \( Z \) has no non trivial factorisation, the partition \( \{1; \ldots; c\} = I \sqcup J \) is trivial. We must have \( J = \emptyset \), \( I = \{1; \ldots; c\} \). Equivalently \( Z = S_1 \). In other words \( Z \) is special, and in particular is weakly special.

This finishes the proof of Theorem 1.2.

7.3. Refined Pila-Wilkie theorem. The following is a variant of Pila-Wilkie Theorem, which replaces the “block version” of Pila-Wilkie Theorem used by Orr. We believe this variant is easier to understand and use, and will be of independent interest.

We deduce the following from [37, Th. 1.7].

**Theorem 7.1.** Let \( W \) be an affine algebraic variety defined over \( \mathbb{Q} \), let \( X \) be an affine algebraic variety over \( \mathbb{R} \) and let \( p : W_{\mathbb{R}} \to X \) be a morphism of algebraic varieties defined over \( \mathbb{R} \).

Let \( Z \subset X(\mathbb{R}) \) be a definable subset, and denote \( Z^{alg} \) be the union of the semialgebraic subsets of \( X(\mathbb{R}) \) which are contained in \( Z \) and of non-zero dimension.

We consider a height function \( H_W \) on \( W(\mathbb{Q}) \) associated to some affine embedding. Then

\[
|Z \setminus Z^{alg} \cap p(\{w \in W(\mathbb{Q}) : H_W(w) \leq T\})| = T^{o(1)}.
\]

Explicitly, for every \( \epsilon \in \mathbb{R}_{>0} \), there exists \( C(\epsilon, Z) \in \mathbb{R}_{>0} \), such that

\[
\forall T \gg 0, |Z \setminus Z^{alg} \cap p(\{w \in W(\mathbb{Q}) : H_W(w) \leq T\})| \leq C(\epsilon, Z) \cdot T^\epsilon.
\]

**Comment.** The theorem still holds with a semi-algebraic map \( p : W(\mathbb{R}) \to X(\mathbb{R}) \) instead of the real algebraic \( p : W_{\mathbb{R}} \to X \). This slight generalisation will not be needed.

The height function we use here is denoted \( H^{proj} \) by Pila, and is not the Height function he uses in his statements. As mentioned in the introduction of [37], it is possible to invoke his statements with \( H^{proj} \) instead.
Proof. We choose affine embeddings
\[ W \subseteq \mathbb{A}^n \quad \text{and} \quad X \subseteq \mathbb{A}^m \]
defined over \( \mathbb{Q} \) and \( \mathbb{R} \). We can then write the morphism
\[ p(w_1, \ldots, w_n) = (P_1(w_1, \ldots, w_n), \ldots, P_m(w_1, \ldots, w_n)) \]
with polynomials \( P_1, \ldots, P_m \in \mathbb{R}[T_1, \ldots, T_n] \). Let \( E \) be the finite dimensional \( \mathbb{Q} \)-vector subspace of \( \mathbb{R} \) generated by the coefficients of these polynomials.

We have
\[ p(W(\mathbb{Q})) \subseteq E^m. \]
We choose an isomorphism \( \iota : E \to \mathbb{Q}^d \) of \( \mathbb{Q} \)-vector spaces. For every \( P_i \) the map
\[ \iota \circ P_i : W(\mathbb{Q}) \to E \to \mathbb{Q}^d \]
is polynomial with coefficients in \( \mathbb{Q} \). This can be checked for every monomial of \( P_i \). The height on \( E^m \) considered in [37, Th. 1.7] can be written, with our notations,
\[ H_E = H \circ (\iota, \ldots, \iota) \]
where \( H \) is the usual height on \( \mathbb{Q}^{d \cdot m} \). It follows from the general “functoriality” properties of heights of §4.2 that
\[ H_E \circ p \preccurlyeq H_W \text{ on } W(\mathbb{Q}). \]
Explicitly, for some \( a, b \in \mathbb{R}_{>0} \) we have
\[ p(\{ W \in W(\mathbb{Q}) : H_W(w) \leq T \}) \subseteq \{ e \in E^m : H_E(e) \leq a + T^b \}. \]
We apply [37, Th. 1.7] and obtain
\[ |(Z \setminus Z^a) \cap p(\{ w \in W(\mathbb{Q}) : H_W(w) \leq T \})| \leq |(Z \setminus Z^a) \cap \{ e \in E^m : H_E(e) \leq a + T^b \}| = T^{o(1)}. \]

Appendix A. Exponentials of \( p \)-adic matrices

In this section we fix a prime \( p \), an integer \( d \in \mathbb{Z}_{\geq 1} \) and denote by \( M_d(\mathbb{Q}_p) \) the space of square matrices of size \( d \) with entries in \( \mathbb{Q}_p \). For \( Z \in M_d(\mathbb{Q}_p) \) we denote by \( \chi_Z(T) = \det(TZ - 1) \in \mathbb{Q}_p[T] \) its characteristic polynomial. Let \( | \cdot | \) be the normalised absolute value on \( \mathbb{Q}_p \), extended to \( \mathbb{T}_p \): we have \( |p| = 1/p \) and \( |1/d| \leq d \) for \( d \in \mathbb{Z}_{\geq 1} \). We denote the norm of \( Z \), and the local height of \( Z \) by
\[ \|Z\| = \max_{1 \leq i,j \leq d} |Z_{i,j}| \quad \text{and} \quad H_p(Z) = \max\{1; \|Z\|\} = H_p(1 + Z). \]
We define, whenever the corresponding series converges in $M_d(\mathbb{Q}_p)$,
\[
\exp(Z) = \sum_{n \in \mathbb{Z}_{\geq 0}} \frac{1}{n!} \cdot Z^n \quad \text{and} \quad \log(1 + Z) = - \sum_{n \in \mathbb{Z}_{\geq 1}} \frac{(-1)^n}{n} \cdot Z^n.
\]

It is well known (see [46, Ch. 5. §4.1]) that, on $\mathbb{C}_p$, the series $\exp(T)$ has radius of convergence $|p|^{-\frac{1}{p-1}}$ and the series $\log(1 + T)$ has radius of convergence 1. It is also true that $\exp(Z)$, resp. $\log(1 + Z)$ converges if and only if the eigenvalues of $Z$ are in the open disc of convergence of $\exp(T)$ resp. $\log(1 + T)$. (For the archimedean case, see [21, §1]. The relevant arguments carry over to ultrametric fields.)

**Proposition A.1.** Let $Y \in M_d(\mathbb{Q}_p)$ be such that $\log(1 + Y)$ converges. Then

\[(63) \quad \chi_Y(T) \in T^d + p\mathbb{Z}_p[T]. \]

Let $Y \in M_d(\mathbb{Q}_p)$ be such that

\[(64) \quad \chi_Y(T) \in T^d + p\mathbb{Z}_p[T]. \]

Then $\log(1 + Y)$ converges and we have

- in general,

\[(65) \quad \|\log(1 + Y)\| \leq d \cdot H_p(Y)^{d-1}, \]

- and for $p > d$, the sharper estimate

\[(66) \quad \|\log(1 + Y)\| \leq H_p(Y)^{d-1}. \]

We deal with the first conclusion (63).

**Proof.** Let $\lambda_1, \ldots, \lambda_d$ be the eigenvalues of $Y$, with repetitions. As can be seen on a Jordan form after passing to $\mathbb{C}_p$, the series $\log(1 + Y)$ converges if and only if every $\log(\lambda_1), \ldots, \log(\lambda_d)$ converges. As the radius of convergence of $\log(1 + T)$ is 1, this means

\[(67) \quad \forall i \in \{1; \ldots; d\}, |\lambda_i| < 1. \]

Let $K = \mathbb{Q}_p(\lambda_1, \ldots, \lambda_d)$, let $O_K$ be its ring of integers, and $\mathfrak{m}_K$ be the maximal ideal of $O_K$. Then (67) means

\[\{\lambda_1; \ldots; \lambda_d\} \subseteq \mathfrak{m}_K. \]

We deduce that the non leading coefficients of

\[\chi_Y(T) = \prod_{i=1}^d (T - \lambda_i)\]
are in $\mathfrak{m}_K$. We recall that $\mathbb{Q}_p \cap \mathfrak{m}_K = p\mathbb{Z}_p$ and $\chi_Y(T) \in \mathbb{Q}_p[T]$. We conclude that

$$\chi_Y(T) \in \mathbb{Q}_p[T] \cap (T^d + \mathfrak{m}_K \cdot O_K[T]) = T^d + p \cdot \mathbb{Z}_p[T].$$

We have proved (63) and before proving the rest of Prop. A.1, we prove an estimate on $\|Y^n\|$ for $n \in \mathbb{Z}_{\geq 0}$.

**Proof.** We consider

$$A := \mathbb{Z}_p + \mathbb{Z}_p \cdot Y + \ldots + \mathbb{Z}_p \cdot Y^{d-1}.$$ 

By hypothesis, we have $\chi_Y(T) = c_0 + \ldots + c_{d-1} T^{d-1} + T^d$ with $c_0, \ldots, c_{d-1} \in p\mathbb{Z}_p$. Let us first check that

$$YA \subseteq A$$

on a generating family: for $0 \leq i < d - 1$ we have $Y \cdot Y^i \in A$ by construction; for $i = d - 1$ the identity $\chi_Y(Y) = 0$ can be rearranged into

$$Y^d = -c_0 + \ldots - c_{d-1} Y^{d-1} \in pA.$$ 

Repeated use of (68) implies that, for $i \in \mathbb{Z}_{\geq 0}$, we have $Y^iA \subseteq pA$. But $Y^d \in pA$ by (69), hence $Y^d \cdot Y^i = Y^i \cdot Y^d \in pA$. Applied to $i = 0, \ldots, d - 1$ it implies $Y^dA \subseteq pA$ and by induction $(Y^d)^kA \subseteq p^kA$. We deduce again that $Y^i \cdot (Y^d)^k \in p^kA$. Writing $n = k \cdot d + i$ with $k = \left\lfloor \frac{n}{d} \right\rfloor$, we get the formula

$$Y^n \in p^{\left\lfloor \frac{n}{d} \right\rfloor} A$$

and the bound

$$\|Y^n\| \leq |p|^{\left\lfloor \frac{n}{d} \right\rfloor} \cdot \|A\|$$

where $\|A\| := \max_{a \in A} \|a\|$. Using the ultrametric inequality $\|X + Z\| \leq \max\{\|X\|; \|Z\|\}$ and sub-multiplicativity $\|X \times Z\| \leq \|X\| \cdot \|Z\|$ of the norm, we get

$$\|A\| \leq \max\{\|Y^0\|; \ldots; \|Y^{d-1}\|\} \leq \max\{1; \ldots; \|Y\|^{d-1}\} = H_p(\|Y\|^{d-1}).$$

We apply our estimate to the series $\log(1 + T)$ and finish the proof of Proposition A.1.

**Proof.** For the series $\log(1 + Y)$ the above (70) and (71) imply the bound

$$\left\| \frac{(-1)^n}{n} \cdot Y^n \right\| \leq \left| \frac{1}{n} \right| \cdot |p|^{\left\lfloor \frac{n}{d} \right\rfloor} \cdot H_p(\|Y\|^{d-1}).$$
We note that \( \lim_{n \to \infty} \left| \frac{1}{n} \right| \cdot |p|^{\left| \frac{n}{d} \right|} = 0 \) which implies that \( \log(1 + Y) \) converges, and that
\[
\max_{n \in \mathbb{Z}_{\geq 1}} \left| \frac{1}{n} \right| \cdot |p|^{\left| \frac{n}{d} \right|} = \left| \frac{1}{d - 1} \right| = \left| \frac{1}{d - 1} \right|.
\]
By the ultrametric inequality and previous estimates,
\[
\log(1 + Y) \leq \sup_{n \in \mathbb{Z}_{\geq 1}} \left\| \frac{(-1)^n}{n} \cdot Y^n \right\| \leq \left| \frac{1}{d - 1} \right| \cdot H_p(Y)^{d - 1}.
\]
As we used the normalised \( p \)-adic norm, we have \( \left| \frac{1}{d - 1} \right| \leq d - 1 \leq d \) in general, and \( \left| \frac{1}{d - 1} \right| = 1 \) if \( p \geq d \). This gives (65) and (66) respectively. 

The main statement of this section will require the following observation.

**Lemma A.2.** Let \( Z \in M_d(\mathbb{Q}_p) \) be such that \( \exp(Z) \) converges and let us write \( \exp(Z) = 1 + Y \). Then \( \log(1 + Y) \) converges and
\[
\log(1 + Y) = Z.
\]

**Proof.** For \( d = 1 \), it is [46], §5, prop. 3.

For \( d > 1 \), it is [46] §6.1.1 applied to \( (\partial/\partial Y)^i \log(1 + Y) \circ \exp \). 

The following statement is one of our main tools for proving lower bounds for Galois orbits.

**Theorem A.3** (Lemma of the exponentials). Let \( X \in M_d(\mathbb{Q}_p) \) be such that \( \exp(X) \) converges and denote by \( \exp(X)^\mathbb{Z} \) the subgroup generated by \( \exp(X) \) in \( GL_d(\mathbb{Q}_p) \).

Then

- in general, we have
\[
\left[ \exp(X)^\mathbb{Z} : \exp(X)^\mathbb{Z} \cap GL_d(\mathbb{Z}_p) \right] \geq H_p(X)/d
\]
- and, if \( p > d \), we have more sharply
\[
\left[ \exp(X)^\mathbb{Z} : \exp(X)^\mathbb{Z} \cap GL_d(\mathbb{Z}_p) \right] \geq H_p(X).
\]

**Proof.** For every \( i \in \mathbb{Z} \), we know that if \( \exp(X) \) converge, then \( \exp(iX) \) converges as well, and we have
\[
\exp(iX) = \exp(X)^i.
\]
By A.2, with \( Y_i = \exp(i \cdot X) - 1 \), we have convergence and identity
\[
\log(1 + Y_i) = i \cdot X.
\]
The Proposition A.1 gives
\[ \| i \cdot X \| = \| \log(1 + Y_i) \| \leq d \cdot H_p(1 + Y_i)^{d-1} \] (75)
and, if \( d \leq p \), \[ \| i \cdot X \| = \| \log(1 + Y_i) \| \leq H_p(1 + Y_i)^{d-1}. \] (76)

Assume that
\[ i = [\exp(X)^Z : \exp(X)^Z \cap GL_d(Z_p)] < +\infty. \]
Then \( H_p(1 + Y_i) = H_p(\exp(X)^i) = 1 \), resp. (75), and (76), specialises to
\[ |i| \cdot \| X \| \leq d, \text{ resp. } |i| \cdot \| X \| \leq 1. \]

Recall that \(|i| \leq \frac{1}{p}\) as we use the normalised \( p \)-adic absolute value. The conclusions (73), resp. (74), follow. \( \square \)

We finish with a sufficient criterion for \( \exp(X) \) to converge.

**Theorem A.4.** Let \( X \) be a matrix in \( M_d(Q_p) \) and \( b \in \mathbb{Z}_{\geq 1} \) be such that
\[ \chi_X(T) \in T^d + p^k Z_p[T] \text{ and } d < k(p - 1). \]
Then \( \exp(X) \) converges.

**Proof.** By the usual criterion, it is sufficient to prove that every eigenvalue \( \lambda \) of \( X \) is in the open disc of convergence for \( \exp(T) \). This amounts to proving the inequality \( |\lambda| < |p|^{\frac{1}{p-1}}. \)

For any eigenvalue \( \lambda \) of \( X \), we have \( \chi_X(\lambda) = 0 \) hence \( \lambda^d \in p^k Z_p[\lambda] \) by assumption. It follows \( |\lambda|^d \leq |p|^k \), that is \( |\lambda| \leq |p|^\frac{k}{d}. \) Using the inequality \( d < k(p - 1) \), it implies \( |\lambda| < |p|^\frac{1}{p-1}. \) \( \square \)

**Appendix B. Heights bounds for adelic orbits of linear groups**

Our bound on \( p \)-adic exponentials is combined with structure theory of linear algebraic groups to obtain the following general lower bound. It is applied to Galois orbits in section 6.

**Theorem B.1.** Let \( M \leq GL(N) \) be a linear algebraic subgroup defined over \( \mathbb{Q} \), denote by \( \phi_0 : M \to GL(N) \) the identity morphism and \( W \) the \( GL(N) \)-conjugacy class of \( \phi_0 \). We define
\[ M(\hat{Z}) = M(\mathbb{A}_f) \cap GL(N, \hat{Z}) \] and \( m_{\hat{Z}} = m \otimes \mathbb{A}_f \cap gl(N, \hat{Z}) \).

We consider the standard Weil \( \mathbb{A}_f \)-height function, see (16),
\[ H_f : \text{Hom}(m \otimes \mathbb{A}_f, gl(N) \otimes \mathbb{A}_f) \to \mathbb{Z}_{\geq 1} \]
given for instance by \( H_f(\Phi) = \min\{ n \in \mathbb{Z}_{\geq 1} : n\Phi(m_{\hat{Z}}) \subset gl(N, \hat{Z}) \}. \)
There exists \( c = c(\phi_0) \in \mathbb{R}_{>0} \) such that, as \( \phi \) ranges through \( W(\mathbb{A}_f) \), we have

\[
\tag{77} [\phi(M(\hat{\mathbb{Z}})) : \phi(M(\hat{\mathbb{Z}})) \cap GL(N, \hat{\mathbb{Z}})] \geq \frac{1}{c \omega(f, d\phi)} \cdot H_f(d\phi).
\]

(Where \( \omega(n) \) counts the number of prime factors of \( n \).)

**Corollary B.2.** We have

\[
\tag{78} [\phi(M(\hat{\mathbb{Z}})) : \phi(M(\hat{\mathbb{Z}})) \cap GL(N, \hat{\mathbb{Z}})] \geq H_f(d\phi)^{1-o(1)}
\]

and, if \( M \) is reductive and connected and \( \iota : W \to \mathbb{A}^d \) is an affine embedding, then, as \( \phi \) ranges through \( W(\mathbb{A}_f) \),

\[
\tag{79} H_{\iota,f}(\phi) \approx H_f(d\phi) \approx [\phi(M(\hat{\mathbb{Z}})) : \phi(M(\hat{\mathbb{Z}})) \cap GL(N, \hat{\mathbb{Z}})].
\]

Furthermore, for every \( \Phi \in \text{Hom}(m \otimes \mathbb{A}_f, \mathfrak{gl}(N) \otimes \mathbb{A}_f) \), we have

\[
\tag{80} \forall m \in M(\hat{\mathbb{Z}}), g \in G(\hat{\mathbb{Z}}), H_f(g \circ \Phi \circ m) = H_f(\Phi).
\]

**Proof.** One passes from (77) to (78) by recalling the known estimate (see [20, 22.10])

\[
c_2^{\omega(n)} \leq n^{\frac{\log(c_2)}{\log \log n}} \cdot \frac{1+o(1)}{\log \log n} = n^{o(1)}.
\]

As for (79), we know that \( W \) is affine as \( M \) is reductive, and \( \phi \mapsto d\phi \) is an affine embedding because \( M \) is connected. Lastly, two heights functions on \( W \) are polynomially equivalent, so we may replace \( H_{W,f}(\phi) \) by \( H_f(d\phi) \) and this follows from (78).

The identity in (80) follows from the observations

\[
m \cdot m_{\hat{\mathbb{Z}}} = m_{\hat{\mathbb{Z}}}, \text{ and } k^{-1} \cdot \mathfrak{gl}(N, \hat{\mathbb{Z}}) = \mathfrak{gl}(N, \hat{\mathbb{Z}})
\]

and the defining property we provided: we have \( n \cdot k \cdot \Phi(mm_{\hat{\mathbb{Z}}}) \subset \mathfrak{gl}(N, \hat{\mathbb{Z}}) \) if and only if

\[
n\Phi(m_{\hat{\mathbb{Z}}}) = n\Phi(mm_{\hat{\mathbb{Z}}}) \subset k^{-1}\mathfrak{gl}(N, \hat{\mathbb{Z}}) = \mathfrak{gl}(N, \hat{\mathbb{Z}}).
\]

\[\square\]

The combination of Th. C.1 (100) with (79) gives the following.

**Theorem B.3.** Let \( M \leq GL(N) \) be a connected reductive linear algebraic subgroup defined over \( \mathbb{Q} \), denote \( \phi_0 : M \to GL(N) \) the identity morphism and \( W \) the \( GL(N) \)-conjugacy class of \( \phi_0 \), and let \( \iota : W \to \mathbb{A}^d \) be an affine embedding. Then, as \( \phi \) ranges through \( W(\mathbb{A}_f) \),

\[
\tag{81} H_{\iota,f}(\phi) \approx H_f(d\phi) \approx [\phi(M(\hat{\mathbb{Z}})) : \phi(M(\hat{\mathbb{Z}})) \cap GL(N, \hat{\mathbb{Z}})].
\]
B.1. The global theorem B.1 will follow directly from (82) in the analogous local theorem below.

**Theorem B.4.** We keep $M$, $\phi_0$, $W$ and $H_f$ as in Theorem B.1.

For every prime $p$, let $H_f: \text{Hom}(m \otimes \mathbb{A}_f, \mathfrak{gl}(N) \otimes \mathbb{A}_f) \to \mathbb{Z}_{\geq 1}$ be given by $H_f(\Phi) = \min\{p^k \in p^{Z_{\geq 1}} : p^k \Phi(m_{Z_p}) \subset \mathfrak{gl}(N, \mathbb{Z}_p)\}$.

There exists $c = c(\phi_0) \in \mathbb{R}_{>0}$ such that, for every prime $p$, and every $\phi \in W(\mathbb{Q}_p)$,

$$[\phi(M(\mathbb{Z}_p)) : \phi(M(\mathbb{Z}_p)) \cap \text{GL}(N, \mathbb{Z}_p)] \geq \frac{H_f(d\phi)}{c}$$

and if $m_{Z_p}$ is generated over $\mathbb{Z}_p$ by nilpotent elements and $p > N$,

$$[\phi(M(\mathbb{Z}_p)) : \phi(M(\mathbb{Z}_p)) \cap \text{GL}(N, \mathbb{Z}_p)] \geq H_f(d\phi).$$

Here is how to deduce Th. B.1 from Th. B.4.

**Proof.** Let us multiply the inequalities (82) for the $\omega(H_f(d\phi))$ primes dividing $H_f(d\phi)$ with the trivial inequalities

$$[\phi(M(\mathbb{Z}_p)) : \phi(M(\mathbb{Z}_p)) \cap \text{GL}(N, \mathbb{Z}_p)] \geq 1$$

for all the other primes. Then one can identify the product on both sides with the corresponding sides of (77). \hfill \Box

Theorem B.4 will follow from different cases gathered in Theorem B.5.

**Theorem B.5.** We keep the notations from Theorem B.4. For every prime $p$, let $K_p := \text{GL}(N, \mathbb{Z}_p)$ and, for any $U \leq G(\mathbb{Q}_p)$, let $[U]_p := [U : U \cap K_p]$. We write $N^* = \text{lcm}(1, \ldots, N)$ so that $|1/N^*|_p = p^{[\log_p(N)]}$ and $|N^*|_p = 1$ if $p > N$.

1. For every prime $p$ we have $\exp(2p m_{Z_p}) \leq M(\mathbb{Z}_p)$ and

$$[\phi(\exp(2p m_{Z_p})))_p \geq [2p N^*]_p H_f(d\phi) \geq \frac{1}{2N_p} \cdot H_f(d\phi).$$

2. Assume that $M$ is unipotent or more generally that $m_{Z_p}$ is generated over $\mathbb{Z}_p$ by nilpotent elements, then

$$[\phi(M(\mathbb{Z}_p))]_p \geq [N^*]_p H_f(d\phi).$$

3. Assume that $M$ is an algebraic torus. There is $c_2 = c_2(\phi_0) \in \mathbb{R}_{>0}$ such that for every prime $p$, and every $\phi \in W(\mathbb{Q}_p)$,

$$\frac{\phi(M(\mathbb{Z}_p))}{\phi(\exp(2p m_{Z_p})) \cdot \phi(M(\mathbb{Z}_p)) \cap K_p} \geq \frac{p}{c_2}.$$
Proof. The bound (83) follows from (85), and the observation that $|N^*|_p = p^{\log_p(N)} = p^0 = 1$ for $p > N$.

Let $U$ be the unipotent radical of $M^0$ and $L$ be a reductive Levi subgroup of $M^0$ so that we have the Levi decomposition $\mathfrak{m} = \mathfrak{u} + \mathfrak{l}$. By the principle B.1.1 we may assume $M = U$ or $M = L$.

In the first case $M = U$, one deduces (82), with $c = N^* \geq |1/N^*|_p$, from (85).

In the second case, $M = L$ is reductive, and thus generated by algebraic tori. By the principle B.1.1 we may assume that $M$ is a torus.

Let us mention a simpler argument giving the following weaker conclusion, which is sufficient for the purpose of this article:

\begin{equation}
\phi(M(\mathbb{Z}_p)) : \phi(M(\mathbb{Z}_p)) \cap GL(N, \mathbb{Z}_p) \geq \frac{H_p(d\phi)^{1/2}}{c_2}.
\end{equation}

Proof. We know that $H_p(d\phi)$ is a power $p^k$ of $p$. For $k = 0$, we may take $c = 1$. For $k = 1$ we deduce from conclusion (3) of Th. B.5 that\footnote{The bound (88) is from [15, Prop. 4.3.9].}

\begin{equation}
[\phi(M(\mathbb{Z}_p))]_p \geq p/c_2 = \frac{H_p(d\phi)}{c_2}.
\end{equation}

For $k \geq 2$, we have $H_p(d\phi)/p \geq \sqrt{H_p(d\phi)}$ and we take $c_2 = 2N$ and use (84).

We now explain how to improve upon the exponent $1/2$.

We suppose that $p$ large enough, that $p \neq 2$, and that the reduction $T_{\mathbb{F}_p}$ of $T$ is a torus over $\mathbb{F}_p$. Then $T_{\mathbb{F}_p}(\mathbb{F}_p)$ is diagonalisable over $\mathbb{F}_p$ and its elements have order prime to $p$, and thus the order $|T_{\mathbb{F}_p}(\mathbb{F}_p)|$ is prime to $p$.

Form the exact sequence

\[0 \to p \cdot t_{\mathbb{Z}_p} \xrightarrow{\exp} T(\mathbb{Z}_p) \to T_{\mathbb{F}_p}(\mathbb{F}_p)\]

we deduce that $U := \exp(pt_{\mathbb{Z}_p}) \leq T(\mathbb{Z}_p)$ is a topological $p$-group and $\frac{T(\mathbb{Z}_p)}{U_p} \hookrightarrow T(\mathbb{F}_p)$ has order prime to $p$.

Thus for any open subgroup $H \leq T(\mathbb{Z}_p)$, we have

\begin{equation}
[T(\mathbb{Z}_p) : H] = [T(\mathbb{Z}_p) : U_p \cdot H] \cdot [U_p : U_p \cap H].
\end{equation}

We now choose $H$ defined by $\phi(H) = K_p \cap \phi(T(\mathbb{Z}_p))$. We have

\begin{equation}
[T(\mathbb{Z}_p) : H] = [T(\mathbb{Z}_p)]_p, \quad [U_p : U_p \cap H] = [U_p]_p
\end{equation}

and

\begin{equation}
[T(\mathbb{Z}_p) : U_p \cdot H] = \left| \frac{\phi(T(\mathbb{Z}_p))}{\phi(\exp(2pt_{\mathbb{Z}_p})) \cdot \phi(M(\mathbb{Z}_p)) \cap K_p} \right|.
\end{equation}
Substituting (90) and (91) in (89) yields

\[
T(Z_p)_p = [U_p)_p \cdot \left( \frac{\phi(T(Z_p))}{\phi(\exp(2ptZ_p)) \cdot \phi(M(Z_p)) \cap K_p} \right).
\]

We now use (89) and (84) and (86) from Theorem B.5 and conclude

\[
[T(Z_p)]_p \geq \frac{1}{2N} \cdot H_p(d\phi) \cdot \frac{p}{c} = \frac{1}{2cN} H_p(d\phi).
\]

We now prove Theorem B.5.

**Proof of conclusion 1.** Assume for now the claim that \(\exp\) converges on \(2p_m\{m\}\) and \(U := \exp(2p_m\{m\}) \leq M(Z_p).\) Let \(X_1, \ldots, X_k\) be generators of \(m_{Z_p}\), then

\[
H_p(d\phi) = \max\{H_p(d\phi X_1); \ldots; H_p(d\phi X_k)\}.
\]

As \(U_i := \exp(2pX_i) \leq U\) for every \(i \in \{1; \ldots; k\}\) we have

\[
[\phi(U)]_p = [\phi(U) \cdot K_p/K_p] \geq [\phi(U_i) \cdot K_p/K_p] = [\phi(U_i)]_p,
\]

and thus

\[
[\phi(U)]_p \geq \max\{\exp(2p \cdot d\phi(X_i))^Z\}_p.
\]

According to Th. A.3 for \(X = 2p \cdot d\phi(X_i)\) we have

\[
[\exp(2p d\phi(X_i))^Z]_p \geq |N^*_p \cdot H_p(2p \cdot d\phi(X_i))|.
\]

We remark

\[
H_p(2p \cdot d\phi(X_i)) = \max\{1; \|2p \cdot d\phi(X_i)\|\}
\geq |2p|_p \cdot \max\{1; \|d\phi(X_i)\|\} = |2p|_p \cdot \|d\phi(X_i)\|.
\]

Substituting (96) into (95) and (95) into (94), we get

\[
[\phi(U_p)]_p \geq |2pN^*_p \cdot \max_{i=1,\ldots,k} H_p(d\phi(X_i)) = |2pN^*_p \cdot H_p(d\phi).
\]

We now recall why, for \(2pX \in 2pm_{Z_p}\), the series \(\exp(2pX)\) converges and \(\exp(2pX) \in M(Z_p)\) for \(2pX \in 2xm_{Z_p}\).

**Proof.** We remark that \(\exp(2pT) \in \mathbb{Z}[[X]]\) and recall that the \(p\)-adic radius of \(\exp(2pT)\) is \(2 \cdot p/p_\infty > 1\). For \(2pX \in 2pm_{Z_p}\), we have \(\|X\| \leq 1\) and so \(\exp(2pX)\) converges. We have \(\exp(2pX) \in M(d, Z_p)\) because \(\exp(2pT) \in \mathbb{Z}[[X]]\) has \(Z_p\) entries. Likewise \(\exp(2pX)^{-1} = \exp(-2pX) \in M(d, Z_p)\) and we conclude \(\exp(2pX) \in GL(N, Z_p)\). □

Conclusion 1 has been proved. □
Proof of conclusion 2. Let $X_1, \ldots, X_k$ be a nilpotent basis of $m_{\mathbb{Z}_p}$. Then the $d\phi(X_1), \ldots, d\phi(X_k)$ generate $d\phi(m_{\mathbb{Z}_p})$ and there exists an $i \in \{1; \ldots; k\}$ such that $H_p(d\phi) = H_p(d\phi(X_i))$. Because $X_i$ is nilpotent, we have
\[
\exp(N^* \cdot X_i) = 1 + N^* \cdot X_i + \ldots + \frac{1}{(N - 1)!}(N^* \cdot X_i)^{N - 1}
\]
and thus $\exp(N^* \cdot X_i) \in M(\mathbb{Z}_p)$.

Thus
\[
[\phi(M(\mathbb{Z}_p))]_p \geq [\phi(\exp(N^* \cdot X_i))]_p.
\]
Finally, by (73), we have
\[
[\phi(\exp(N^* \cdot X_i \cdot \mathbb{Z}_p))]_p \geq H_p(d\phi(N^* \cdot X_i))/N.
\]
Because $H_p(d\phi(N^* \cdot X_i))$ and $[\phi(\exp(N^* \cdot X_i \cdot \mathbb{Z}_p))]_p$ are powers of $p$, we actually have
\[
[\phi(\exp(N^* \cdot X_i \cdot \mathbb{Z}_p))]_p \geq |N|_p \cdot H_p(d\phi(N^* \cdot X_i)) \geq |N|^p \cdot H_p(d\phi).
\]

Conclusion 3 is due to [15] and we detail how their formulation [15, Prop. 4.3.9] relates to ours.

Proof of conclusion 3. We can discard finitely many primes and assume $p$ is big enough so that [15, Prop. 4.3.9] and its proof applies.

We first notice that, in the matrix algebra $M(N, \mathbb{Q})$, the subalgebra $\mathbb{Q}[T(\mathbb{Q})]$ contains $t$.

Proof. The inclusion of vector spaces can be checked after passing to $\mathbb{R}/\mathbb{Q}$. We know that
\[
\mathbb{R}[T(\mathbb{Q})] = \mathbb{R}[T(\mathbb{R})]
\]
because, by weak approximation, $T(\mathbb{Q})$ is dense in $T(\mathbb{R})$. Let $t$ be a sufficiently small element in $t \otimes \mathbb{R}$, so that $\log(\exp(t))$ converges and $\log(\exp(t)) = t$. Then $t \in \mathbb{R}[\exp(t)]$, as is seen using Jordan forms, and $\exp(t) \in T(\mathbb{R})$. Because $t \otimes \mathbb{R}$ admits a basis of such elements, we can conclude.

We can choose $t_1, \ldots, t_k$ in $\mathbb{Q}[T(\mathbb{Q})]$ so that
\[
t \subset t_1 \cdot \mathbb{Q} + \ldots + t_k \cdot \mathbb{Q}
\]
and thus $t_1 \cdot \mathbb{Z} + \ldots + t_k \cdot \mathbb{Z}$ contains a lattice of $t$. It will hence contain $n \cdot (t \cap \mathfrak{gl}(N, \mathbb{Z}))$ for some commensurability index $n \in \mathbb{Z}_{\geq 1}$.

As we discard finitely many primes $p$, we may assume that $p$ do not divide the denominators of the $t_i$ and do not divide $n$. We will then have
\[
t_1, \ldots, t_k \in T(\mathbb{Z}_p)
\]
and
\[(97)\quad \mathfrak{t}_{Z_p} = \mathfrak{t} \cap \mathfrak{gl}(N, Z_{(p)}) \subset t_1 \cdot Z_{(p)} + \ldots + t_k \cdot Z_{(p)},\]
and, applying \(\otimes_{Z_{(p)}} Z_p\), we may replace \(Z_{(p)}\) by \(Z_p\).

Let \(\phi \in W(Q_p)\). Using Th. 2.11, we can write
\[\phi = g\phi_0 g^{-1}\]
for some \(g \in GL(N, Q_p)\). We assume \(H_p(d\phi) \neq 1\), that is
\[gt_{Z_p}g^{-1} \not\subset \mathfrak{gl}(N, Z_p),\]
and, by \((97)\), there is at least one \(i \in \{1; \ldots; k\}\) such that
\[gt_i g^{-1} \not\subset \mathfrak{gl}(N, Z_p).\]
Equivalently \(gt_i g^{-1} \not\subset GL(N, Z_p)\), which also means
\[t_i \cdot gZ_p^d \neq gZ_p^d.\]
As \(t_i \in T(Z_p)\), this implies, in the sense of [15, Prop. 4.3.9] (for \(W_{Z_p} = gZ_p^d\)),
\[“T_{Z_p} \text{ does not fix } \{W_{Z_p}\}”\]
Looking into the proof of [15, Prop. 4.3.9] we notice that their lower bound is given by a lower bound of some orbit of \(T(F_p)\), thus, in \((88)\), there exists \(n \in \mathbb{Z}_{\geq 1}\) such that \(n\) divides \(|T(F_p)|\) and
\[\left[\phi(T(Z_p))\right]_p \geq n \geq p/c.\]
In the factorisation \((92)\) the first factor in the right-hand side is a power of \(p\) and prime to \(n\). Thus the inequality \(\left[\phi(T(Z_p))\right]_p \geq n\) comes from the second factor, i.e. we have inequality of Conclusion 3. \(\square\)

B.1.1. **Subgroup principle.** The following elementary lemmas were useful in passing to subgroups in the proofs of Theorems B.1, B.4 and B.5. Proofs are left to the reader.

**Lemma B.6** (Global subgroup principle). Let \(M_1, \ldots, M_k \leq M \leq GL(N)\) be algebraic groups over \(\mathbb{Q}\) such that \(m_1 + \ldots + m_k = m\).

\[\text{(1) Then}\]
\[(98a)\quad \Lambda := m_1 \cap \mathfrak{gl}(N, \mathbb{Z}) + \ldots + m_k \cap \mathfrak{gl}(N, \mathbb{Z}) \leq m \cap \mathfrak{gl}(N, \mathbb{Z})\]
and the index
\[(98b)\quad c = [m \cap \mathfrak{gl}(N, \mathbb{Z}) : \Lambda]\]
is finite. For every prime \(p\), we have
\[(98c)\quad \Lambda \otimes Z_p = m_1 \otimes Q_p \cap \mathfrak{gl}(N, Z_p) + \ldots + m_k \otimes Q_p \cap \mathfrak{gl}(N, Z_p) \leq m \otimes Q_p \cap \mathfrak{gl}(N, Z_p)\]
and

\[(98d)\quad [m \otimes \mathbb{Q}_p \cap \mathfrak{gl}(N, \mathbb{Z}_p) : \Lambda \otimes \mathbb{Z}_p] = \frac{1}{|c|_p} \]

with \(|1/c|_p \leq c\) and \(|1/c|_p = 1\) if \(\gcd(c, p) = 1\).

(2) Assume moreover that, for some morphism \(\phi : M \to \text{GL}(d)\) defined over \(\mathbb{Q}\), we have

\[(98e)\quad [\phi(M_i(\widehat{\mathbb{Z}})) : \phi(M_i(\widehat{\mathbb{Z}})) \cap \text{GL}(d, \widehat{\mathbb{Z}})] \geq \frac{H_f(d\phi)}{c_i}.\]

Then we have, with \(c = n \cdot \max\{c_1; \ldots; c_k\}\),

\[(98f)\quad [\phi(M(\widehat{\mathbb{Z}})) : \phi(M(\widehat{\mathbb{Z}})) \cap \text{GL}(d, \widehat{\mathbb{Z}})] \geq \frac{H_f(d\phi)}{c}.\]

**Lemma B.7** (Local subgroup principle). Let \(p\) be a prime and \(M_1, \ldots, M_k \leq M \leq \text{GL}(N)\) be algebraic groups over \(\mathbb{Q}_p\).

(1) Then

\[(99a)\quad [M(\mathbb{Z}_p)]_p \geq \max_{i \in \{1; \ldots; k\}} [M_i(\mathbb{Z}_p)]_p.\]

(2) Assume that \(m_1 + \ldots + m_k = m\), then the index

\[(99b)\quad [m_{\mathbb{Z}_p} : \Lambda] = n\]

is a finite power of \(p\).

(3) With \(n\) as above, for any \(\mathbb{Q}_p\) linear map \(\Phi : m \to \mathfrak{gl}(d, \mathbb{Q}_p)\), we have

\[(99c)\quad \frac{1}{n} H_p(\Phi) \leq \max_{i \in \{1; \ldots; k\}} H_p(\Phi|_{m_i}) \leq H_p(\Phi).\]

(4) Assume moreover, for some morphism \(\phi : M \to \text{GL}(N)\) defined over \(\mathbb{Q}_p\), that we have \((99c)\) for \(\Phi = d\phi\) and that

\[(99d)\quad \forall i \in \{1; \ldots; k\}, [M_i(\mathbb{Z}_p)]_p \geq \frac{1}{c_i} \cdot H_p(d\phi).\]

Then we have, with \(c = n \cdot \max\{c_1; \ldots; c_k\}\),

\[(99e)\quad [M(\mathbb{Z}_p)]_p \geq \frac{1}{c} \cdot H_p(d\phi).\]

**APPENDIX C. Upper bound on Adelic orbits**

In this appendix, we prove upper bounds on adelic orbits. Combined with Prop. 3.6 this implies corresponding upper bounds on Galois orbits. This is not used in the proof of our main result but we believe can be useful in other contexts.
Theorem C.1. Let $M \leq G$ be reductive groups over $\mathbb{Q}$, and $K \leq G(\mathbb{A}_f)$ be a compact open subgroup and $K_M \leq K \cap M(\mathbb{A}_f)$ be a compact subgroup.

Let $\phi_0 : M \to G$ be the inclusion monomorphism, and $W = G : \phi_0$ be the conjugacy class of $\phi_0$, as an algebraic variety.

Let $\iota : W \hookrightarrow \mathbb{A}_N$ be an affine embedding, and let $H_f$ be as defined in (16). Then we have, as $\phi$ describes $W(\mathbb{A}_f)$,

$$[\phi(K_M) : \phi(K_M) \cap K] \leq H_{\iota,f}(\phi). \tag{100}$$

We prove a more precise version. Let $\rho : G \hookrightarrow GL(d)$ be a faithful representation and let us identify $G$ with $\rho(G)$. In the associative algebra $\text{End}(\mathbb{Q}^N)$, we denote the subalgebras linearly generated by $M(\mathbb{Q})$ and $G(\mathbb{Q})$ by

$$B_M := \sum_{m \in M(\mathbb{Q})} \mathbb{Q} \cdot m \quad \text{and} \quad B_G := \sum_{g \in G(\mathbb{Q})} \mathbb{Q} \cdot g.$$ 

Let $\Phi_0 : B_M \to B_G$ denote the inclusion. We have $M(\mathbb{Q}) \subseteq B_M$, and $G(\mathbb{Q}) \subseteq B_G$, and $\phi_0 : M(\mathbb{Q}) \to G(\mathbb{Q})$ is the restriction of $\Phi_0$.

For every field extension $L/\mathbb{Q}$, and $\phi = g \cdot \phi_0 \cdot g^{-1} \in W(L)$, with $g \in G(L)$, the map

$$B_\phi = g \cdot \Phi_0 \cdot g^{-1} : B_M \otimes L \to B_G \otimes L$$

is a $L$-linear extension of $\phi$ to $B_M \otimes L$, and is the unique $L$-linear extension.

We choose linear bases of $B_M$ and $B_G$ generating $B_M \cap \text{End}(\mathbb{Z}^d)$ and $B_G \cap \text{End}(\mathbb{Z}^d)$ respectively, and we consider the corresponding isomorphism $\text{Hom}(B_M, B_G) \simeq \mathbb{Q}^{\dim(B_M) \cdot \dim(B_G)}$. Then $\phi \mapsto B_\phi$ induces an affine embedding $\iota_\rho : W \hookrightarrow \text{Hom}(B_M, B_G) \simeq \mathbb{Q}^{\dim(B_M) \cdot \dim(B_G)}$.

Theorem C.2. Define $G(\widehat{\mathbb{Z}}) := G(\mathbb{A}_f) \cap GL(d, \widehat{\mathbb{Z}})$ and $M(\widehat{\mathbb{Z}}) := M(\mathbb{A}_f) \cap GL(d, \widehat{\mathbb{Z}})$. Then, for every $\phi \in W(\mathbb{A}_f)$, we have

$$[\phi(M(\widehat{\mathbb{Z}})) : \phi(M(\widehat{\mathbb{Z}})) \cap G(\widehat{\mathbb{Z}})] \leq H_{\iota_{\rho,p}}(\phi)^{2+d^2}.$$ 

We note that if $G$ is of adjoint type, we can use the adjoint representation and pick $d = \dim(G)$.

Let us prove Th. C.2.

Proof. We endow $\text{Hom}(B_M \otimes \mathbb{Q}_p, B_G \otimes \mathbb{Q}_p)$ with the norm

$$\|\Phi\| = \min\{p^k \in p^{\mathbb{Z}} : \forall m \in B_M \otimes \mathbb{Q}_p \cap \text{End}(\mathbb{Z}_p^d), p^k \cdot \Phi(m) \in B_G \otimes \mathbb{Q}_p \cap \text{End}(\mathbb{Z}_p^d)\}. \tag{101}$$

We note that $H_{\iota_{\rho,p}}(\phi) = \max\{1; \|B_\phi\|\}$. 
It suffices to prove that, for every prime \( p \), and \( \phi \in W(\mathbb{Q}_p) \), we have
\[
\tag{102} [\phi(M(\mathbb{Z}_p)) : \phi(M(\mathbb{Z}_p)) \cap G(\mathbb{Z}_p)] \leq \|B_\phi\|_p^{2+d^2}. \]
Let us write \( \|B_\phi\|_p = p^k \). Then, in the notations of Lemma C.3, we have
\[
\phi(M(\mathbb{Z}_p)) \subseteq S(d, p, p^k). \]
Thus (102) follows from (103). \( \square \)
We deduce Th. C.1 from Th. C.2.

**Proof.** The assumptions imply the finiteness of
\[
C_M := [K_M : K_M \cap M(\hat{\mathbb{Z}})] = [\phi(K_M) : \phi(K_M) \cap \phi(M(\hat{\mathbb{Z}}))] \]
and
\[
C_G := [G(\hat{\mathbb{Z}}) : K \cap G(\hat{\mathbb{Z}})]. \]
We have
\[
[\phi(K_M) : \phi(K_M) \cap K] \leq C_M \cdot C_G \cdot [\phi(M(\hat{\mathbb{Z}})) : \phi(M(\hat{\mathbb{Z}})) \cap G(\hat{\mathbb{Z}})]. \]
By Prop. 4.1, we have \( H_f \approx H_{\psi,f} \). Using (101), we conclude
\[
[\phi(K_M) : \phi(K_M) \cap K] \leq C_M \cdot C_G \cdot H_{\psi,f}(\phi)^{2+d^2} \approx H_f(\phi). \]
\( \square \)

**Lemma C.3.** Let \( p \) be a prime, \( d \) be in \( \mathbb{Z}_{\geq 0} \), and \( k \) be in \( \mathbb{Z}_{\geq 0} \).
Define \( S(d, p, p^k) = \{ b \in \text{End}(\mathbb{Q}_p^d) : \|b\| \leq p^k, \det(b) \in \mathbb{Z}_p^x \} \).
Then \( S(d, p, p^k) = S(d, p, p^k) \cdot GL(d, \mathbb{Z}_p) \) and
\[
\tag{103} #S(d, p, p^k)/GL(d, \mathbb{Z}_p) \leq (p^k)^{2+d^2}. \]

**Proof.** We endow \( \text{End}(\mathbb{Q}_p^d) \) with the additive Haar measure \( \mu \) normalised by \( \mu(B(1)) = 1 \), where \( B(p^k) \), for \( k \in \mathbb{Z}_{\geq 1} \) is the ball of radius \( p^k \). One knows that the Haar measure satisfies \( \mu(g \cdot A) = \|\det(g)\| \cdot \mu(A) \).
For \( A = B(1) \) and \( g = p^k \cdot \text{Id} \) this yields
\[
\mu(S(d, p, p^k)) \leq \mu(B(p^k)) = (p^k)^{d^2}. \]
For \( b \in GL(N, \mathbb{Q}_p) \) such that \( \det(b) \in \mathbb{Z}_p^x \) this yields
\[
\mu(b \cdot GL(d, \mathbb{Z}_p)) = \mu(GL(d, \mathbb{Z}_p)). \]
One can also check
\[
\tag{104} \mu(GL(d, \mathbb{Z}_p)) = \frac{\#GL(d, \mathbb{F}_p)}{\#\text{End}(\mathbb{F}_p^d)} = \prod_{i=1}^d 1 - \frac{1}{p^i} \geq \prod_{i=1}^\infty 1 - \frac{1}{2^i} \geq 0.25 \geq 1/p^2. \]
The norm multiplicativity $\|b \cdot g\| = \|b\| \cdot \|g\|$ implies the right invariance
\begin{equation}
S(d, p, p^k) = S(d, p, p^k) \cdot GL(d, \mathbb{Z}_p).
\end{equation}
Equivalently, we can write $S(d, p, p^k) = b_1 \cdot GL(d, \mathbb{Z}_p) \sqcup \ldots \sqcup b_c \cdot GL(d, \mathbb{Z}_p)$, with $c = \#S(d, p, p^k)/GL(d, \mathbb{Z}_p)$.

Using (104), we deduce
\[
\#S(d, p, p^k)/GL(d, \mathbb{Z}_p) = \mu(S(d, p, p^k))/\mu(GL(d, \mathbb{Z}_p)).
\]

Assume $k = 0$. Then (103) follows from $S(d, p, p^k) = GL(d, \mathbb{Z}_p)$ and $\#S(d, p, p^k)/GL(d, \mathbb{Z}_p) = 1 \leq 1^{2+d^2}$.

We may now assume $k \geq 1$. Then (103) follows from
\[
\#S(d, p, p^k)/GL(d, \mathbb{Z}_p) \leq p^2 \cdot (p^k)^{d^2} \leq (p^k)^{2+d^2}.
\]

\hfill \Box
