²Department of Otorhinolaryngology, Faculty of Medicine, Udayana University/Sanglah Hospital Denpasar from January 2017 to December 2018 were included in the inclusion criteria.

Abstract

Introduction: Nasopharyngeal carcinoma is the most common malignancy in the ENT field. The cause of nasopharyngeal carcinoma is multifactorial. One of the risk factors for an increase in nasopharyngeal carcinoma is the rs2070672 polymorphism of the CYP2E1 gene.

Objective: To determine the rs2070672 CYP2E1 gene polymorphism proportion in early and advanced stage undifferentiated type NPC subjects in Balinese.

Method: This research is a cross-sectional comparative study. The case population was all subjects with undifferentiated type NPC in the ENT outpatient clinic at Sanglah General Hospital Denpasar. This study uses 65 samples. Data collected in the form of subject characteristics and rs2070672 CYP2E1 gene polymorphisms which examined by the ARMS-PCR technique.

Result: The average age of the sample was 48.1 years, the most were male as many as 48 subjects (73.8%), and the highest was the advanced stage as many as 56 subjects (86.2%). In the chi-square test, the proportion of polymorphisms in the advanced stage was 2.357 times higher than the early stages. The results of the multivariate analysis using logistic regression proved that the rs2070672 CYP2E1 gene polymorphism at the advanced stage was 7.469 times higher than the early stage.

Conclusion: There is a difference in the proportion of rs2070672 CYP2E1 gene polymorphism in undifferentiated type NPC of Balinese, where the advanced stage is higher than the early stage.

1. INTRODUCTION

Nasopharyngeal carcinoma (NPC) is a malignancy of the surface epithelium in the nasopharynx. The incidence rate in men has doubled compared to women. The incidence of NPC is 1.2 per 100,000 populations per year, with diverse geographical spreads throughout the world [1]. The prevalence of NPC in Indonesia is highest in the 4-5 decade with a ratio between men and women is 2:3:1 and reaches 4.7 per 100,000 populations per year [2].

Nasopharyngeal carcinoma risk factors consist of internal and external factors. Internal factors are genetic mechanisms. External factors are Epstein-Barr virus (EBV) infection, exposure to cigarette smoke, wood dust, formaldehyde, and consuming preserved food [3].

One of the genes polymorphisms at risk for NPC is the cytochrome P450 family 2 subfamily E polypeptide 1 (CYP2E1) gene that codes for the CYP2E1 enzyme for activation of procarcinogens [4]. The highest prevalence of NPC in Indonesia is in Yogyakarta (4.1‰), followed by Central Java (2.1‰), Bali (2‰), Bengkulu, and Jakarta with 1.9‰ respectively [5]. Study of the relationship of CYP2E1 gene polymorphism with the risk of NPC in Yogyakarta with buffy coat isolation DNA of 119 male NPC patients and 119 controls of Javanese men showed mutant alleles at rs3813865 and rs2070672 increased the risk of NPC and the progression of the disease, whereas the mutant allele of rs3813867 reduced the risk of NPC [6].

The rs2070672 polymorphism of the CYP2E1 gene is one of the NPC biomarkers that need to be investigated because there is a strong association between the polymorphism of the rs2070672 CYP2E1 gene with the incidence of NPC. Research on the rs2070672 polymorphism of the CYP2E1 gene in subjects with NPC in Indonesia is still rare, while it has never been studied in Bali.

2. MATERIAL AND METHODS

A total of 65 undifferentiated type NPC in Balinese subjects who underwent nasopharyngeal biopsy at Sanglah Hospital and histopathological examination at the Anatomy Pathology Laboratory of the Faculty of Medicine, Udayana University/Sanglah Hospital Denpasar from January 2017 to December 2018 were included in the inclusion criteria. Samples were taken by consecutive sampling. The study was conducted in August - September 2019. This is an observational study with cross-sectional comparative study design. Data were analyzed by univariate, bivariate, and multivariate analysis. Characteristics of the study subjects included age, gender, clinical stage of undifferentiated type NPC, and rs2070672 polymorphism of the CYP2E1 gene. The statistical test used was the Chi-Square Test by looking at 95% confidence interval (CI) and the p-value at the significance of 0.05. Multivariate analysis was done using logistic regression. Data processing is performed using the SPSS computer program vers. 22.0 for Windows.

3. RESULT

This study using 65 samples conducted in August-September 2019.

Table 1. Characteristic of subject

| Characteristic | n=65 |
|---------------|------|
| Age (year)    |      |
| Average±SD    | 48±11.1 |
| Min-Max       | 17-73 |
| Gender        |      |
| Male          | 48 (73.8%) |
| Female        | 17 (26.2%) |
Table 1 shows that the average age of the subjects was 48.1 years with a standard deviation of 11.1 years. The youngest is 17 years old and the oldest is 73 years old. The gender proportion is male as many as 48 subjects (73.8%) and female as many as 17 subjects (26.2%).

Table 2. Clinical stage of an undifferentiated type of NPC

| Variable | Clinical stage | n (%) |
|----------|---------------|-------|
| T (Tumor) | Stage I | 1 (1.5%) |
| | Stage II | 2 (3.1%) |
| | Stage III | 14 (21.6%) |
| | Stage IV | 16 (24.6%) |
| | Advanced | 34 (52.3%) |
| N (Node) | 0 | 9 (13.8%) |
| | 1 | 18 (27.7%) |
| | 2 | 16 (24.6%) |
| | 3 | 22 (33.9%) |
| M (Metastasis) | 0 | 63 (96.9%) |
| | 1 | 2 (3.1%) |

Distribution based on the clinical stage of a undifferentiated type of NPC in this study was stage II in 9 subjects (13.8%), stage III in 12 subjects (18.5%), stage IVa in 19 subjects (29.2%), and stage IVb as many as 25 subjects (38.5%). Initial stages were found in 9 subjects (13.8%) and advanced stages as many as 56 subjects (86.2%). This result is in correspond with Hasibuan et al. (2014), whose obtain 62.5% subjects with stage IV NPC and none stage INPC [7]. Study in Europe obtain as many as 39.1% of early stage NPC and 60.9% of late stage NPC [8]. Study in Djamil Hospital Padang obtain as many as 13.64% of early stage NPC and 86.3% of late stage NPC. This shows patients come in the late stage. Nasopharyngeal carcinoma often shows minimal or unspecified sign, so it often found in late stage with lymph node enlargement and intracranial invasion [9].

Table 3. Allele and rs2070672 polymorphism CYP2E1 gene

| Variable | Allele rs2070672 CYP2E1 gene | n (%) |
|----------|-------------------------------|-------|
| Allele AA | 18 (27.7%) |
| Allele AG | 12 (18.3%) |
| Allele GG | 30 (46.0%) |
| Polymorphism Present | 47 (72.3%) |
| Not present | 18 (27.7%) |

The proportion of allele rs2070672 CYP2E1 gene in subjects with undifferentiated type NPC in this study was 18 AA allele (27.7%), AG allele in 8 subjects (12.3%), and GG allele in 39 subjects (60.0%). The proportion of rs2070672 polymorphism of CYP2E1 gene in subjects with undifferentiated type NPC were polymorphisms (allele AG and GG) in 47 subjects (72.3%) and no polymorphisms/wild types (AA alleles) in 18 subjects (27.7%).

Study by Yin (2012) shows SNP rs2070672 G allele (GG) homozygote found in 7.9% from 447 subjects compare with 3.1% from 487 control. GG genotype is related with increased risk NPC compared with GA and AA genotype (OR = 3.57 and 9.5% CI: 1.66 – 7.66 recessive inherited) [10].

Table 4. The proportion of rs2070672 polymorphism CYP2E1 gene based on the clinical stage of undifferentiated type NPC in Balinese

| Variable | Polymorphism | PR | 95% CI | P |
|----------|--------------|----|--------|---|
| Stage | Advanced | Present | 44 (78.6%) | 0.608 |
| | Early | Present | 12 (21.4%) | 0.011 |
| | Early | Not present | 3 (5.5%) | 0.002 |

The in advanced stage, as many as 44 subjects (78.6%) and early stages as many as 3 subjects (33.3%) experienced polymorphism rs2070672 CYP2E1 gene. Patients with advanced-stage NPC as many as 12 subjects (21.4%) and early-stage as many as 6 subjects (66.7%) who did not experience polymorphism in rs2070672 CYP2E1 gene (wild type). Chi-square test results obtained the proportion of polymorphism in the advanced stage is 2.357 times compared to the early stage with a confidence interval (CI) 0.926-5.998 and a p-value = 0.011 (P<0.05), meaning statistically significant.

Table 5. The result of multivariate analysis (logistic regression)

| Variable | Adjusted Odds Ratio | 95% CI | P |
|----------|---------------------|--------|---|
| Polymorphism | 7.469 | 3.566-15.177 | 0.011 |
| Age | 1.005 | 0.939-1.076 | 0.877 |
| Gender | 1.533 | 0.289-8.357 | 0.608 |

The results of the multivariate analysis using logistic regression proved that the rs2070672 polymorphism of the CYP2E1 gene at an advanced stage was 7.469 times higher than the early stage with a confidence interval (CI) 1.586-35.177 and P-value = 0.011 (P<0.05) after controlling for age and sex.

4. DISCUSSION

A total of 65 subjects were included in this study with ages ranging from 17 to 73 years with an average age of 48.1±11.1 years. This shows that the age distribution in the study subjects is normal and in accordance with the existing literature, NPC rarely occurs at the age of fewer than 20 years. This is consistent with Razek and King's research, which states that the peak age of nasopharyngeal carcinomas is 40-60 years [11]. In Cantonese, the incidence increases with age and peaks at the age of 40-59 years and then decreases [12]. In Turkey, NPC occurs mostly at the age of 40-50 years [13]. It is estimated that about 80% of NPC is found at the age of 35-50 years with a peak age of 40-49 years [14]. NPC most commonly occurs at the age of 40-49 years at Cipto Mangunkusumo Hospital in Jakarta and more than 80% of patients are diagnosed at the age of 30-59 years [15].

Cancer cells arise from normal cells that are transformed into malignant due to spontaneous mutations or induction of carcinogens. Long induction time is needed from the time of contact with carcinogens to the appearance of cancer cells, up to 15-30 years [16]. NPC tends to occur at the age of more than 40 years because of a decreased immune system which cannot eliminate tumor antigens or EBV viruses properly. DNA repair mechanism that is not functioning properly causes failure to repair gene mutations resulting in uncontrolled cell growth. The incidence of NPC is often found at the age of more than 40 years related to the length of exposure to carcinogenic substances such as nitrosamines found in salted fish and cigarette consumption for more than 25 years [3].

There were more male than female NPC patients in this study, as many as 48 subjects (73.8%), with a ratio of 2.8:1. This is consistent with several other studies that found the proportion of men with NPC was greater than women with a ratio of 2:3:1 [12]. Nurdiansyah et al. stated the ratio of men and women to be 2:1 [13]. Adham et al. stated the comparison according to gender are 70.4% in men and 29.6% in women with a ratio of 2:4:1 [15]. Hasibuan et al. reported the incidence rate of NPC in males and females was 3:1 [7]. The high incidence in men is thought to be due to occupational factors and life habits that are more often exposed to carcinogens [13].

The distribution of subjects based on the clinical stage of undifferentiated type NPC in the Balinese was an early stage as many as 9 subjects (13.8%) and an advanced stage as many as 56 subjects (86.2%). This is in accordance with several studies such as Hasibuan et al. as many as 62.5% of patients with stage IV NPC and no patient in stage I [7]. Research in Europe found 39.1% of patients with early-stage NPC and 60.9% of patients with advanced-stage [7]. Research in Padang Djamil Hospital stated early-stage NPC in 13.64% and advanced stages in 86.36%. This shows that most of the patients come for treatment at an advanced stage. The diagnosis of NPC is often made late because the location of the nasopharynx is hidden behind the nasal cavity and under the base of the skull so that NPC patients generally come for treatment at an advanced stage. In addition, NPC often exhibits minimal or nonspecific symptoms so it often found at an advanced stage with enlarged lymph nodes and intracranial invasion [9].

The description of the rs2070672 allele CYP2E1 gene in undifferentiated type NPC patients in Balinese was AA allele in 18 subjects (27.7%), AG allele in 8 subjects (12.3%), and GG allele in 39 subjects (60.0%). This shows that the majority of NPC patients in this study experienced polymorphisms (alleles AG and GG) as many as 47 subjects (72.3%).
5. CONCLUSION

There is a difference in the proportion of rs2070672 polymorphism of the CYP2E1 gene in patients with an undifferentiated type of NPC in Balinese, which advanced stage is 2.357 times higher than the early stage.
