Abstract. An experimental and modeling approach was developed in this research to investigate the effects of CO₂, new synthesized CaO and commercial SiO₂ nanoparticle concentrations on the Asphaltene Precipitation Envelope (APE). First, the effects of different temperatures and CO₂ concentrations on asphaltene precipitation trends were observed. Second, the impact of CaO and SiO₂ nanoparticle concentrations on asphaltene precipitation were observed in the presence of CO₂ at different temperatures. Third, Advanced Redlich-Kwong-Soave (RKSA) equation of state (EOS) was considered to modify Multiflash (Infochem Co.) software from the aspect of entering physical characteristics of CaO and SiO₂ nanoparticles as pseudo components. Fourth, the developed model was used for predicting the effects of CO₂, CaO and SiO₂ concentrations on APE in ranges that no experimental data existed. At constant CO₂ concentration and temperature during natural depletion, asphaltene precipitation increased above saturation pressure, while below saturation pressure, asphaltene precipitation decreased (solution gas evolved from crude oil and made it richer). As temperature increased at constant CO₂ concentration, asphaltene precipitation decreased, while it was observed that the saturation pressures increased. Although two different trends were observed in upper asphaltene onsets at different temperatures and CO₂ concentrations, in wide ranges of data, as temperature increased, asphaltene upper onset pressure increased. CaO and SiO₂ nanoparticles decreased asphaltene precipitations in the presence of CO₂, but CaO had better applications for reducing asphaltene precipitation. The proposed Software/RKSA EOS model was in good agreement with the obtained experimental data, and it was applicable for predicting the effects of CO₂, CaO and SiO₂ nanoparticles concentration on APE.

1 Introduction

Crude oil has main fractions including Saturates, Aromatics, Resins and Asphaltenes. Asphaltenes contain carbon, hydrogen and heteroelements including oxygen, sulfur and nitrogen [1]. Asphaltene's stability depends on asphaltene characteristics and crude oil's properties, and disturbed asphaltene's stability causes asphaltene precipitation [2, 3]. Asphaltene precipitation occurred due to changes in pressures, temperatures and compositions, which created a serious problem in the production of reservoir oil [4–16]. Precipitated asphaltene caused many problems in wellbore tubing and equipment [14].

Bouts et al. [17] investigated the interactions between crude oil's fractions and asphaltenes. It was observed that the asphaltene precipitation decreased at a high ratio of resin to asphaltene, and the resin polar head coated asphaltene molecules and the nonpolar parts interacted directly with oil [17]. Asphaltenes stability was analyzed by many methods including: the Colloidal Instability Index (CII) [18, 19], De Boer’s diagram [20], Refractive index [3] and hydrogen to carbon ratio [21]. Asphaltenes Precipitation Envelopes (APE), gravimetric, acoustic resonance, near-infrared light scattering and filtration were the most common methods for detecting the severity of asphaltenes [20]. Akbarzadeh et al. [22] performed a study on the flow assurance problem due to asphaltene precipitation. They found out that due to changes in equilibrium conditions and resin in crude oil, asphaltenes stuck together and these particles came to the surface.

Many asphaltene precipitation treatments were used for solving precipitation problems such as chemical solvent treatment [23], thermal treatments and laser technology [2] and inhibitors such as alkyl phenol, ethoxylated alcohols, phenols, natural resin, and vegetable oil [3]. Since these methods were expensive and nanoparticles had special characteristics including high ability to adsorb asphaltene on its surface and high specific surface volume, researchers used the adsorption of asphaltene on the nanoparticles surface for asphaltene precipitation inhibition [24–29].

Asphaltene characteristics [30], amount of resins [31, 32], solvent polarity [33, 34], particle surface chemistry [35], and temperature and contact time [36–38] were the main parameters that affected the adsorption process. Nassar et al. [24–29] have published several reports on the adsorption of asphaltene on the nanoparticles surface. Based on their results, CaO nanoparticle had the highest adsorption capacity as compared with nanoparticles such as Nicole oxide and Titanium dioxide. CaO had many applications such as biomedical, water purification, adsorption and antibacterial agents [39–41]. Although asphaltene adsorption on CaO nanoparticle was surveyed, almost no work addressed the effects of CaO nanoparticle on asphaltene precipitation reduction, Asphaltene Onset Pressure (AOP) and APE envelope. As the deposition of asphaltenes in the porous media was known as one of the most difficult problems during CO2 flooding [42–46], CO2 and natural depletion tests were used as sources of making asphaltene precipitation in this paper. In the first phases of this paper, the effects of different temperatures and CO2 concentrations on asphaltene precipitation trends were observed. Then, the impacts of CaO nanoparticle concentrations on the asphaltene precipitation were observed in the presence of CO2 at different temperatures. SiO2 nanoparticles have been addressed in many studies for asphaltene inhibition [47–49], so the results of the new synthesized CaO nanoparticles are compared with commercial SiO2 nanoparticles as the next step in this research.

Leontaritis and Mansoori [50] proposed a model for prediction of asphaltene flocculation based on thermodynamics, and asphaltene was considered as a solid particle that was stabilized with resin. Moreover, some models such as those by Wu et al. [51] considered asphaltene as liquid-liquid treatments with oil. Flash calculation between liquid-vapor-asphalt was used as another method for the modeling of asphaltene precipitation during gas injection and pressure depletion, which was proposed by Nghiem et al. [52]. The proposed model was not good at high concentrations of gas concentration. Victorov and Firoozabadi [53] performed experimental works based on the miscelization model, and the proposed model was in good agreement with many experimental works. However, it was not good for the prediction of asphaltene during gas flooding. Although multiphase simulators such as Pipesim, Well Flo, Eclipse 300 and Olga are used for investigating the system that contains asphaltene under normal and abnormal conditions [54, 55], having software for modeling the inhibitor or nanoparticles as an inhibitor is completely necessary. Accordingly, in the second phases of this paper, the Advanced Redlich-Kwong-Soave (RKSA) equation of state was considered to modify Multiflash (Infochem Co.) software from the aspect of entering physical characteristics of synthesized CaO and commercial SiO2 nanoparticles as pseudo components. Finally, the developed model was used for predicting the effects of different parameters such as CaO and SiO2 nanoparticles and CO2 concentrations on APE in ranges that no experimental data existed. Using software is cost-effective and this study can be a source of the first preliminary attempt at modeling nanoparticles as asphaltene inhibitors.

### Table 1. Properties of crude oil used in PVT modeling.

| Components Separated oil (mole. %) | Separated gas (mole. %) | Reservoir oil (mole. %) |
|-----------------------------------|-------------------------|------------------------|
| H2S                              | 0.00                    | 0.13                   | 0.01                  |
| N2                               | 0.00                    | 0.91                   | 0.08                  |
| CO2                              | 0.00                    | 6.71                   | 0.56                  |
| C1                               | 0.00                    | 41.38                  | 3.44                  |

2 Experimental

2.1 Materials and methodology

A crude oil was selected from an Iranian reservoir in the west of Iran. Table 1 shows properties of crude oil and Saturate-Aromatic-Resin-Asphaltene (SARA) test results, which are used in PVT modeling.

Equation (1) expressed CII, and if the CII value is more than 0.9, it shows very unstable conditions [56, 57]. According to the SARA results in the current study, CII is 1.392, which confirms that crude oil is located in an unstable region.

\[
CII = \frac{\text{Saturates} + \text{Asphaltenes}}{\text{Aromatics} + \text{Resins}}
\]

Asphaltene is extracted by the IP143 method. Nassar et al. [28] carried out a study on asphaltene extraction’s protocol. Briefly, asphaltene was diluted with n-heptane at a volume ratio of 40/1 and mixtures remained in the dark box for 24 h. Then Whatman paper was used for filtration of pure asphaltene. Hydrophobic commercial SiO2 and synthesized CaO were used as nanoparticles for precipitation tests. CaO, 20 nm were synthesized based on Singh and Singh’s [58] work, and SiO2 was bought from Houston Brand company. The SEM of these two nanoparticles is shown in Figure 1.

CaO and SiO2 nanoparticles were stirred in crude oil solution for 6 h and sonicated for 30 min to stay stable in crude oil.

2.2 Natural depletion tests in presence of different concentrations of carbon dioxide (CO2)

Figure 2 shows the schematic of the apparatus for measuring asphaltene precipitation during CO2 and depletion tests. The set up mainly contained PVT cell, recombination sampling cells, hydraulic pumps, 0.5 micron filter, CO2 cylinder, IP143 set up and oven. Samples including: A) crude oil and separator gas; B) crude oil containing CaO and separator gas; C) crude oil containing SiO2 and separator gas were prepared, and a recombination was performed for 2 weeks at reservoir pressure and temperature. Then, the prepared samples were transferred from recombination cell2 to PVT cell3 and the desired concentration of CO2 was injected to the PVT cell and kept for 24 h at the desired pressure and temperature. Next, the sample was passed through a 0.5 micron metal filter4 and the sample was collected in a sampling cell. Asphaltene and nanoparticles, which adsorbed asphaltene on their surface and had a size of more than 0.5 microns, could not cross the filter. Finally, the sample was obtained from the sampling cell, and asphaltene content was calculated from the IP143 method. Asphaltene precipitation was calculated from the difference between asphaltene content in the PVT cell sample and the obtained sample in the sampling cell.

3 Results and discussion

3.1 Experimental

3.1.1 Effects of carbon dioxide (CO2) concentrations and temperatures on asphaltene precipitation during natural depletion

Figure 3 shows the effects of CO2 concentrations (10%, 20% and 30%) and temperatures (80 °C, 90 °C and 100 °C) on asphaltene precipitation during natural pressure depletions. Two different trends were seen during natural pressure depletions. Above saturation pressure, asphaltene precipitation increased while below saturation pressure asphaltene precipitation decreased. The maximum amount of asphaltene precipitations occurred at saturation pressures. The reasons for these trends were understood by the solubility approach. Briefly, at constant temperature and during natural depletion above saturation pressure, density and fluid power decreased. However, by decreasing pressure below saturation pressure, solution gas evolved from crude oil and oil became subsequently richer [59, 60].

According to the results in Figure 3, as temperature increased from 80 °C to 100 °C, asphaltene precipitation decreased while it was seen that the saturation pressures increased due to an increase of temperatures. Results were different and inconsistent with each other regarding the
relation of temperature and asphaltene precipitation in the literature [61–63]. Recently, our group studied the influence of different temperature ranges on asphaltene precipitation with high pressure and high temperature experiments to survey the effects of temperature on asphaltene precipitation in heavy oil reservoirs. According to the natural depletion results, asphaltene precipitation increased from 60 °C to 80 °C and decreased from 80 °C to 96.1 °C [63]. Thus, these results are in good agreement with the current results in this paper regarding the effects of temperature on asphaltene precipitation. Hassanvand et al. [61] and Verdiere et al. [62] investigated the effects of temperature on asphaltene precipitation as well. It was shown that as temperature increased, asphaltene particles redissolved and asphaltene precipitation decreased. As it was shown in Figure 3, asphaltene precipitation increased due to the addition of CO2 concentrations. Asphaltenes are high molecular polar compounds, which are stabilized in the presence of resins. Dilution of oil with light hydrocarbons decreased the amount of resin and asphaltenes flocculated and lost their stability.

Table 2 shows experimental upper onset and saturation pressures at different temperatures (80 °C, 90 °C and 100 °C) and CO2 concentrations (10%, 20% and 30%). Two different trends were observed based on experimental data including: 1) CO2 10 mole %, from 90 °C to 100 °C and 2) CO2 10 mole %, from 80 °C to 90 °C; CO2 20 mole %, from 80 °C to 100 °C and CO2 30 mole %, from 80 °C to 100 °C. In the first trend, as temperature increased, asphaltene upper onset pressure decreased while in the second trend, as temperature increased, asphaltene upper onset pressure increased. The second trends were observed to a greater extent in our experimental data. Negahban et al. [64] surveyed the effects of temperature on AOP of live oil. According to their results, as temperatures increased, AOP decreased [64]. This results in a good agreement with the first trend of current research, but is in contrast with the second trend. Novosad and Costain [65], Srivastava and Huang [66], Takahashi et al. [67], and Vazquez and Mansoori [68], showed that as CO2 concentration increased, AOP increased. These results are in good agreement with wide ranges of our experimental data as it was shown in Table 2.

3.1.2 Effects of temperature and hydrophobic nanoparticles type (CaO and SiO2) on asphaltene precipitations in the presence of CO2 during natural depletion

Figure 4 shows the effects of temperature and nanoparticles types including CaO and SiO2 on asphaltene precipitations in the presence of CO2 during natural depletion. Three pressures including 2500, 2000 and 1500 Psi were used and precipitation amounts were obtained in the presence of CaO and SiO2 nanoparticles. According to the precipitation results, as temperature increased from 90 °C to 100 °C during pressure reduction from 2500 Psi to 1500 Psi, CaO decreased asphaltene precipitation from (0.32 wt. %, 0.62 wt. %) to (0.096 wt. %, 0.214 wt. %) and SiO2 decreased asphaltene precipitation from (0.56 wt. %, 1.10 wt. %) to (0.27 wt. %,
Hydrophobic CaO nanoparticles had better application for reducing asphaltene precipitations compared to SiO2 nanoparticles.

Two different trends were observed in upper onset pressures including 80°C/176°F to 90°C/194°F and 90°C/194°F to 100°C/212°F for both CaO and SiO2 nanoparticles. As the temperature increased from 80°C/176°F to 90°C/194°F, AOP increased from 2750 Psi to 2825 Psi and 3100 Psi to 3150 Psi in the presence of CaO and SiO2, respectively. However, as temperature increased from 90°C/194°F to 100°C/212°F, AOP decreased from 2825 Psi to 2790 Psi and 3150 Psi to 3130 Psi in the presence of CaO and SiO2, respectively. Further information is given in Table 3.

Figure 5 compared asphaltene precipitation reductions for CaO and SiO2 nanoparticles at CO2 30 mole % and 80°C. As pressure decreased from 2500 Psi to 1500 Psi, asphaltene precipitation decreased from (0.56 wt. %, 1.1 wt. %) to (0.32 wt. %, 0.68 wt. %) and (0.56 wt. %, 1.1 wt. %) for CaO and SiO2 nanoparticles, respectively. CaO decreased asphaltene precipitations much better than SiO2 nanoparticles.

As discussed above, hydrophobic CaO had better applications for reducing asphaltene precipitations compared to SiO2. The effects of SiO2 and CaO nanoparticles and pressures on the interfacial tension of CO2-crude oil were obtained for a better understanding of this behavior. Table 4 shows the relation of CO2-crude oil interfacial tension versus pressure and different slope regions in the presence of CaO and SiO2 nanoparticles at a constant 0.52 wt. %, respectively. Hydrophobic CaO nanoparticles had better application for reducing asphaltene precipitations compared to SiO2 nanoparticles.

Two different trends were observed in upper onset pressures including 80°C to 90°C and 90°C to 100°C for both CaO and SiO2 nanoparticles. As the temperature increased from 80°C to 90°C, AOP increased from 2750 Psi to 2825 Psi and 3100 Psi to 3150 Psi in the presence of CaO and SiO2, respectively. However, as temperature increased from 90°C to 100°C, AOP decreased from 2825 Psi to 2790 Psi and 3150 Psi to 3130 Psi in the presence of CaO and SiO2, respectively. Further information is given in Table 3.

Figure 5 compared asphaltene precipitation reductions for CaO and SiO2 nanoparticles at CO2 30 mole % and 80°C. As pressure decreased from 2500 Psi to 1500 Psi, asphaltene precipitation decreased from (0.87 wt. %, 1.22 wt. %) to (0.32 wt. %, 0.68 wt. %) and (0.56 wt. %, 1.1 wt. %) for CaO and SiO2 nanoparticles, respectively. CaO decreased asphaltene precipitations much better than SiO2 nanoparticles.

As discussed above, hydrophobic CaO had better applications for reducing asphaltene precipitations compared to SiO2. The effects of SiO2 and CaO nanoparticles and pressures on the interfacial tension of CO2-crude oil were obtained for a better understanding of this behavior. Table 4 shows the relation of CO2-crude oil interfacial tension versus pressure and different slope regions in the presence of CaO and SiO2 nanoparticles at a constant
Table 4. Changes in CO$_2$-oil IFT slope ratio due to adding CaO and SiO$_2$ nanoparticles.

| Nanoparticles type | Nanoparticle concentration (ppm) | Region | Equation IFT (mN/m) | Ratio of the IFT slope in 2nd to 1st region (%) |
|--------------------|----------------------------------|--------|---------------------|-----------------------------------------------|
| Base               | 0                                | 1st    | IFT = −0.0124 $P + 17.675$ | 16.9                                          |
|                    |                                  | 2nd    | IFT = −0.0021 $P + 6.137$   |                                               |
| CaO                | 45                               | 1st    | IFT = −0.0124 $P + 16.675$ | 39.5                                          |
|                    |                                  | 2nd    | IFT = −0.0049 $P + 8.407$  |                                               |
| SiO$_2$            | 45                               | 1st    | IFT = −0.0126 $P + 16.909$ | 31.0                                          |
|                    |                                  | 2nd    | IFT = −0.0039 $P + 7.939$  |                                               |

Fig. 6. Physical properties of nanoparticles (CaO and SiO$_2$) based on the software’s information bank. A) $P_c$ vs. $M_w$; B) $T_c$ vs. $M_w$; C) $V_c$ vs. $M_w$; D) acentric factor vs. $M_w$.

nanoparticle concentration of 45 ppm. Two different slopes were observed for all three crude oil conditions (without nanoparticles, CaO 45 ppm and SiO$_2$ 45 ppm). With an increase of pressure in the first region, IFT decreased due to oil swelling. In the second region, the slope became slower than the first region due to aggregation of asphaltene in the interface of the two fluids (the ratio of the 2nd to 1st ratio was 16.9%). After the addition of nanoparticles, although the first region slope did not change significantly, the slope in the second region increased (39.5% for CaO and 31.0% for SiO$_2$). Interestingly, the slope increased better in the presence of CaO nanoparticles compared to SiO$_2$. Accordingly, CaO adsorbed more asphaltene and had a better function for asphaltene inhibition in comparison to SiO$_2$ nanoparticles. Nassar et al. [26] concluded that basic oxides such as CaO had higher adsorption capacity compared to other oxides, which is in good agreement with our results.

3.2 Modeling

Multiflash software/Advanced Redlich-Kwong-Soave (RKSA) Equation Of State (EOS) model were used for
generating the Asphaltene Precipitation Envelope (APE) in the current study. The RKSA EOS model was stated as Equations (2)–(8), which was proposed by Soave [69].

\[
P = \frac{\text{NRT}}{V - b} + \frac{a}{V(V + b)} \\
\]

\[
a = \sum_{ij} \sqrt{a_i a_j (1 - K_{ij})} n_i n_j \\
\]

\[
b = \sum_i b_i n_i \\
\]

\[
a_i = a_{ci} (1 + K_i (1 - \sqrt{T/T_{ci}}))^2 \\
\]

\[
K_i = C_o + C_i W_i - C_3 W_i^2 \\
\]

\[
b_i = 0.08664 \frac{RT_i}{P_{ci}} \\
\]

\[
a_{ci} = 0.42748 \frac{R^2 T^2_i}{P_{ci}} \\
\]

where, $P_{ci}$, $T_{ci}$, $n_{ci}$, $W$, $R$ and $K_{ij}$ are critical pressure, temperature, molar fractions of components, acentric factor, gas constant and binary interaction between components $i$ and $j$.

The ideal inputs for software are: 1) compositional data of crude oil, 2) SARA test result, 3) experimental data for asphaltene flocculation and 4) saturation pressure for tuning petroleum fractions [70]. The main steps of the software include: A) entering inputs, composition, performing split on composition, SARA analysis, and recombination data, B) selecting models, C) entering experimental data and D) plot phase envelope.

### 3.2.1 Physical properties of nanoparticles (CaO and SiO$_2$) based on the software’s information bank

| Nanoparticle | $T_c$ (K) | $P_c \times 10^5$ (Pa) | $V_c$ (m$^3$/mole) | Acentric factor | $T_b$ (K) |
|--------------|-----------|------------------------|-------------------|----------------|-----------|
| CaO          | 420       | 3.94                   | 0.00023           | 0.17           | 280       |
| SiO$_2$      | 440       | 3.76                   | 0.00028           | 0.2            | 300       |

![Figure 7](image-url) Effects of CO$_2$ concentrations on APE and saturation pressures.
3.2.2 Effects of CO$_2$ and CaO, SiO$_2$ nanoparticle concentrations on APE and saturation pressures based on software

Figure 7 shows the effects of CO$_2$ concentrations on the APE with software. Based on the software results, as CO$_2$ concentration increased, APE increased, which is in good agreement with the experimental data. Moreover, calculated saturations matched well with the experimental data. As CO$_2$ concentration increased from 10 mole % to 30 mole %, saturation pressure increased. As it was mentioned before, two different trends were observed in the presence of CO$_2$ 10 mole % for upper onset pressures including 80–90 °C and 90–100 °C. Interestingly, software and experimental data were in good agreement in this case. Figure 8 shows the effects of nanoparticles (CaO and SiO$_2$) on APE at CO$_2$ 30 mole %. CaO nanoparticles decreased APE better than SiO$_2$ in the presence of CO$_2$ 30 mole % concentration.

3.2.3 Prediction effects of CO$_2$, CaO and SiO$_2$ nanoparticle concentrations on APE and saturation pressures

The previous section shows that the software and experimental data were in good agreement with each other. So in the next step, three different tests were designed for predicting the effects of CaO and SiO$_2$ nanoparticles and CO$_2$ concentrations on APE. The results of these tests were shown in Figure 9, Figure 10 and Figure 11, respectively. As it was observed from the results, the software successfully predicted the effects of both nanoparticles and CO$_2$ concentrations on the APE, and it was applicable for predicting these effects in the range that experimental data did not exist.
4 Conclusion

1) At constant CO₂ concentration and temperature during natural pressure depletion, the above saturation pressure of asphaltene precipitation increased (density and fluid power decreased), while below saturation pressure asphaltene precipitation decreased (solution gas evolves from crude oil and oil becomes richer).

2) At constant CO₂ concentration, as the temperature increased, asphaltene precipitation decreased while it was observed that saturation pressures increased. The reasons were understood from the fact that dilution of oil with light hydrocarbons decreased the amount of resin and asphaltenes flocculated and lost their stability.

3) Based on experimental upper onset and saturation pressures at different temperatures (80°C, 90°C and 100°C) and CO₂ concentration (10%, 20% and 30%) results, there were two different trends including 1) CO₂ 10 mole %, from 90°C to 100°C 2) CO₂ 10 mole %, from 80°C to 90°C; CO₂ 20 mole %, from 80°C to 100°C and CO₂ 30 mole %, from 80°C to 100°C. In the first trend, as temperature increased, asphaltene upper onset pressure decreased while in the second trend, asphaltene upper onset pressure increased due to an increase in temperatures. Additionally, it was observed that the second trends were seen in wide ranges of experimental data.

4) According to the precipitation results in the presence of CaO and SiO₂ nanoparticles, as temperature increased from 90°C to 100°C during pressure reduction from 2500 Psi to 1500 Psi, CaO decreased asphaltene precipitation from (0.32 wt. %, 0.62 wt. %) to (0.096 wt. %, 0.214 wt. %) and SiO₂ decreased asphaltene precipitation from (0.56 wt. %, 1.10 wt. %) to (0.27 wt. %, 0.52 wt. %). Accordingly, hydrophobic CaO had better applications for reducing asphaltene precipitations compared to the SiO₂ nanoparticle.

5) As temperature increased from 80°C to 90°C, AOP increased from 2750 Psi to 2825 Psi and 3100 Psi to 3150 Psi in the presence of CaO and SiO₂, respectively. However, as temperature increased from 90°C to 100°C, AOP decreased from 2825 Psi to 2790 Psi and 3150 Psi to 3130 Psi in the presence of CaO and SiO₂, respectively.

6) Based on the software results, as CO₂ concentration increased, APE increased, which is in good agreement with experimental data. Experimental onset and saturation pressures matched well between experimental data and the proposed model.

7) The software successfully predicted the effects of both nanoparticles and CO₂ concentrations on APE, and it was applicable for predicting these effects in the range that experimental data did not exist.

Acknowledgments. The author would like to thank Amirkabir laboratory research center for preparing apparatuses for performing the tests.
