Background: Vinpocetine (VPN) is a synthetic derivative of the Vinca minor alkaloids. The drug is characterized by a short half-life, limited water solubility and high hepatic first-pass effect. The objective was to develop different lipid-based nanocarriers (NCs) loaded into a thermosensitive in situ gelling (ISG) system to improve VPN bioavailability and brain targeting via intranasal (IN) delivery.

Methods: Different lipid-based NCs were developed and characterized for vesicle size, zeta potential, VPN entrapment efficiency (EE) and morphological characterization using transmission electron microscope (TEM). The prepared NCs were loaded into ISG formulations and characterized for their mucoadhesive properties. Ex-vivo permeation and histological study of the nasal mucosa were conducted. Pharmacokinetic and brain tissue distribution were investigated and compared to a marketed VPN product following administration of a single dose to rats.

Results: VPN-D-α-Tocopherol polyethylene glycol 1000 succinate (TPGS) micelles nano-formulation showed the smallest particle size, highest EE among the studied NCs. TEM images revealed an almost spherical shape for all the prepared NCs. Among the NCs studied, VPN-loaded TPGS micelles demonstrated the highest percent cumulative VPN ex vivo permeation. All the prepared ISG formulations revealed the presence of mucoadhesive properties and showed no signs of inflammation or necrosis upon histological examination. Rats administered IN VPN-loaded TPGS-micelles ISG showed superior VPN concentration in the brain tissue and significant high relative bioavailability when compared to that received raw VPN-loaded ISG and marketed drug oral tablets. VPN-D-α-Tocopherol polyethylene glycol 1000 succinate (TPGS) micelles nano-formulation showed the smallest particle size, highest EE among the studied NCs. TEM images revealed an almost spherical shape for all the prepared NCs. Among the NCs studied, VPN-loaded TPGS micelles demonstrated the highest percent cumulative VPN ex vivo permeation. All the prepared ISG formulations revealed the presence of mucoadhesive properties and showed no signs of inflammation or necrosis upon histological examination. Rats administered IN VPN-loaded TPGS-micelles ISG showed superior VPN concentration in the brain tissue and significant high relative bioavailability when compared to that received raw VPN-loaded ISG and marketed drug oral tablets.

Conclusion: VPN-loaded TPGS-micelles ISG formulation is a successful brain drug delivery system with enhanced bioavailability for drugs with poor bioavailability and those that are frequently administered.

Keywords: brain distribution, lipid based nanocarriers, in situ gel, intranasal, vinpocetine
Introduction

Intranasal (IN) drug administration is characterized by enhanced bioavailability, especially for drugs that easily cross the mucous membranes, due to the enriched vascular supply in the nasal cavity. This route avoids the drug destruction either by gastrointestinal enzymes or by hepatic first-pass effect. Moreover, the rate of absorption and plasma concentration of IN administered drugs are comparable to intravenous administration and are usually better than subcutaneous or intramuscular routes.\(^1\)\(^2\) It is a noninvasive, simple, convenient and safe route for all patients.\(^3\) In addition, IN administration may achieve an effective therapeutic brain drug concentration, through nose–brain pathway, that allows direct delivery to the cerebrospinal fluid.\(^4\)\(^5\) Therefore, IN route can diminish drug distribution to nontargeted sites and decreases systemic adverse effects.\(^6\)\(^7\)\(^8\) Despite these advantages, the IN delivery suffers from some restrictions such as poor drug permeability from nasal mucosa, mucociliary clearance, low drug retention time and nasomucosal toxicity.\(^9\)\(^10\)\(^11\) The rapid nasal mucociliary clearance, that results in low absorption and poor bioavailability, could be overcome by the development of mucoadhesive in situ nasal gelling drug delivery systems that prolong the retention time and control the drug delivery via this route.\(^12\) Such formulations are supposed to help the IN drug delivery but, the clinical success of IN therapy is limited owing to the irritation of the nasal mucosa or owing to the frequent and high dose of the formulation. Hence, our research focused on the development of a suitable lipid-based NCs to overcome these barriers.

Biomolecules as lipids, proteins and carbohydrates have been utilized to fabricate different types of nanoparticulate drug delivery systems that are suitable for delivery of many active pharmaceutical ingredients and appropriate for clinical applications.\(^13\) Among these systems, lipid-based NCs are considered effective drug delivery systems due to their unique formulation components. The classic example of the lipid-based NCs is liposomes that mainly consist of phospholipid bilayers which are the main components of the biological cell membranes.\(^14\) Currently, many liposomal formulations are in clinical use or awaiting clinical trials.\(^15\) In addition to liposomes, transferrones (TFs) and ethosomes are also phospholipid-based NCs that have been reported to be successful alternatives for liposomes.\(^16\)–\(^18\) Recently, solid lipid nanoparticles (SLNs) and nanostructure lipid carriers (NLCs) have been investigated. They are ease to scale up, but both formulations depend on the presence of other lipid components in addition to the phospholipids. Many reports have described the successful development of drug-loaded SLNs and NLCs and their potential application in drug-delivery process.\(^19\)–\(^21\)

Polymeric micelles are nanostructured assemblies that consist of block copolymers of amphiphilic macromolecules. They represent an effective delivery system for poorly soluble drugs.\(^22\) The amphiphilic macromolecules are spontaneously assembled into submicroscopic nanostructures that enclose water-insoluble drugs. D-\(\alpha\)-tocopheryl polyethylene glycol 1000 succinate (TPGS) is formed by conjugation of the hydrophobic vitamin E suc- cinate with the hydrophilic polyethylene glycol.\(^23\) TPGS is a pharmaceutical additive, approved by the United State Food and Drug Administration and is used in different drug formulations to solubilize poorly soluble drugs, enhances cellular drug uptake and prolongs the drug blood circulation time.\(^24\) TPGS is a surfactant (nonionic type) that can be used in the preparation of other nanostructured formulations that utilize surfactants.\(^25\) Moreover, TPGS has been reported to enhance the transport of drug across biological membrane barriers such as brain endothelium and to modify biological response by inhibiting P-glycoprotein (P-gp) that is responsible for decreasing efflux of the drugs from the cells.\(^26\)

Vinpocetine (VPN) is a synthetic alkaloid obtained from the Periwinkle plant. It is used effectively to improve brain blood flow.\(^27\) VPN inhibits phosphodiesterase type-1 enzyme that selectively improves brain blood supply. VPN enhances cerebral circulation and brain oxygen utilization and facilitates blood flow redistribution to ischemic areas. VPN has a limited aqueous solubility (2.4 μg/mL) with pKa =7.31 (weak base), short half-life (1–2 hrs) and poor bioavailability (75% metabolized in liver).\(^28\)\(^29\) So, it would be a benefit for patients utilizing VPN to develop a formulation that improves the drug bioavailability. To the best of our knowledge, no previous studies have investigated the pharmaco- kinetics and brain concentration of VPN from Pluronic-based in situ gel (ISG) preparation loaded with drug lipid-based NCs following IN administration.

In this study, different VPN-loaded lipid-based NCs were formulated and loaded into the ISG system suitable for IN delivery to enhance the drug bioavailability and brain tissue distribution.
Materials and methods

Materials

VPN was procured from Wuhan Trustchem Fine Chemical Co., Ltd. (Wuhan, China). Glycerol monostearate (GMS) was gifted from Nikkol Chemicals Co., Ltd (Tokyo, Japan). Hydrogenated phosphatidylcholine (PC) (95% hydrogenated phosphatidylcholine, 0.5% hydrogenated lyso-phosphatidylcholine) was obtained as a kind gift from American Lecithin company (Oxford, CT, USA). Stearic acid was procured from Fischer Scientific (Loughborough, UK). Dicetyl phosphate (DCP), cholesterol, ethanol and methanol were purchased from Fisher Scientific (Pittsburgh, PA, USA). Poloxamer 407 was obtained from Xi’an Lyphar Biotech Co., Ltd (Xi’an, China). Tween 80, Span 80, polyethylene glycol (PEG) 4000, chloroform and D-α-tocopherol polyethylene glycol 1000 succinate (TPGS) were procured from Sigma-Aldrich (St. Louis, MI, USA). Carbopol 940 was obtained from Acros Organics (Morris Plains, NJ, USA).

Preparation of different VPN-loaded lipid-based NCs

Different optimized VPN-loaded lipid-based NCs, namely, SLNs, TFs, PEGylated liposomes (Peg-Lips) and TPGS-micelles were prepared as described in our previously published work.\textsuperscript{17,18,30–33} Table 1 illustrates the composition of the prepared lipid-based NCs.

| Nanocarrier type | Composition | PS (nm) | PDI | ZP (mV) | EE (%) |
|------------------|-------------|---------|-----|---------|--------|
| **Ingredients**  |             |         |     |         |        |
| SLNs             | GMS (%)     | 386±27  | 0.481 | −3.16±1.45 | 89.01  |
|                  | Surfactant (%) |         |       |         |        |
|                  | Surfactant HLB |         |       |         |        |
|                  | 5           |         | 1    | 11.1    |        |
| TFs              | VPN: PC (molar ratio) | 590±47 | 0.444 | 1.89±1.01 | 97.34  |
|                  | PC: Surfactant (%) |         |       |         |        |
|                  | Surfactant HLB |         |       |         |        |
|                  | 1:4.8       |         | 95.5 | 4.3     |        |
| Peg-Lips         | Hydrogenated PC (%) | 205±73 | 0.494 | −52.27±0.80 | 59.05  |
|                  | Cholesterol (%) |         |       |         |        |
|                  | DCP (%)     |         | 0.25 | 0.3     |        |
|                  | PEG 4000 (%) |         | 0.25 |         |        |
| TPGS-micelles    | TPGS (%)    | 13±2   | 0.484 | −2.79±0.35 | 100    |

Notes: All NCs contain the same concentration of VPN (0.25%). Span and Tween were used as non-ionic surfactant.

Abbreviations: SLNs, solid lipid nanoparticles; PEG, polyethylene glycol; GMS, glyceryl monostearate; VPN, vinpocetine; TPGS, D-α-tocopherol polyethylene glycol 1000 succinate; PS, particle size; ZP, zeta potential; EE, entrapment efficiency; DCP, dicetyl phosphate; PC, phosphatidylcholine.

Preparation of VPN-loaded SLNs

Melt-emulsion ultrasonication and low-temperature solidification were the techniques utilized to develop VPN-loaded SLNs.\textsuperscript{34,35} Briefly, the specified amount of GMS was heated at 80°C and 0.25% w/v of VPN (based on the total volume of the formulation) was solubilized in the lipid phase. An aqueous surfactant (Tween 80, span 80 or both) solution (80°C) was prepared, added to the melted lipid phase and the mixture was stirred at 1200 rpm for 15 mins at 80°C until a milky color emulsion was formed. The prepared primary emulsion was then ultrasonicated for 10 mins using a Sonics VCX 750, Sonics & Materials INC. (Newtown, CT, USA) until a uniform nano-dispersion was formed. The colloidal dispersion was promptly cooled by immersing the container into ice-cold water while stirring on a magnetic stirrer for 15 mins until a homogenous dispersion was obtained.\textsuperscript{31}

Preparation of VPN-loaded TFs

Preparation of VPN-loaded TFs was achieved using lipid film hydration technique,\textsuperscript{36} with some modifications. The specified amount of VPN (250 mg), PC and nonionic surfactant, described in Table 1, were dissolved in methanol using an ultrasonic bath. The obtained dispersion was subjected to rotary evaporation under reduced pressure at 45°C until the complete formation of a thin film on the flask wall. This film was maintained overnight in a vacuum oven to confirm complete removal of organic solvent. Finally, the film was then hydrated with 100 mL PBS (pH =7.5) for about 2 hrs at 19.8°C.\textsuperscript{18}
Preparation of VPN-loaded Peg-Lips
Thin-film hydration technique was utilized to develop VPN-loaded Peg-Lips as previously described with slight modifications. The calculated amounts of VPN (250 mg), hydrogenated PC, cholesterol, DCP and PEG 4000 were dissolved in 40 mL of methanol in chloroform mixture (40% v/v). Organic solvents were removed under vacuum using Buchi Rotavapor R-200; BÜCHI Labortechnik AG (Flawil, Switzerland) at 60°C until a thin film was formed. Traces of the organic solvents were removed after the film was kept overnight in a vacuum oven at 30°C. Multilamellar Peg-Lips were assembled by hydrating the dried lipid film at 60°C with 100 mL of isotonic buffer for about 10 mins. Finally, VPN-loaded Peg-Lips vesicles were subjected to vesicle size reduction using a probe sonicator (Qsonica, LLC., Newtown, CT, USA) for 30 s.

Preparation of VPN-loaded TPGS-micelles
VPN-loaded TPGS-micelles were prepared by dissolving VPN (0.25% w/v) and TPGS (2% w/v) in a 50 mL of ethanol over a magnetic stirrer for about 5 mins. Distilled water (100 mL) was added to the prepared dispersion. Ethanol was completely removed using Buchi Rotavapor R-200; BÜCHI Labortechnik AG (Flawil, Switzerland). The obtained micellar dispersion was kept in a refrigerator at 4°C until further characterization.

NCs characterization
Particle size and zeta potential determination
Malvern Zetasizer Nano ZSP, Malvern Panalytical Ltd (Malvern, United Kingdom), that utilizes the dynamic light scattering with non-invasive backscatter (NIBS) optics technique, was used to determine the particle size and zeta potential of the prepared lipid-based NCs. Measurement for each sample was done in triplicate.

Entrapment efficiency (EE) determination
For VPN-loaded SLNs, TFs and Peg-Lips, the percent EE was determined using an indirect centrifugation method. To isolate the free unentrapped VPN from the prepared NCs, aliquots from each formulation were centrifuged at 20,000 rpm for 1 hr at 4°C. The supernatant was collected and passed through a 0.2-µm filter. VPN concentration was determined using a reported HPLC method, except for slight modifications. Briefly, the mobile phase consisted of methanol and 0.05 ammonium acetate buffer mixture of pH 5.5 (80: 20 v/v). The mobile phase was flowing at a rate of 1 mL/min through a Ponapak C18 analytical column, 4.6×250 I.D. mm, particle size 125A (Waters Associates, Dublin, Ireland). The injection volume was adjusted at 20 µL and the detection wavelength was set at 273 nm. The % VPN entrapped in each NCs formulation was calculated using Equation 1.

\[ EE(\%) = \frac{\text{Initial amount of VPN used} - \text{Amount of unentrapped VPN in the supernatant}}{\text{The initial amount of VPN used}} \times 100 \] (1)

For VPN-loaded TPGS-micelles, the prepared micellar dispersion was centrifuged at 20,000 rpm for 5 mins at 4°C to separate unloaded VPN. The supernatant, which contained VPN-loaded TPGS-micelles, was collected, diluted with anhydrous ethanol and the drug concentration was determined using the HPLC method described above. EE% was calculated using Equation 2.

\[ EE(\%) \text{ in micelles} = \frac{\text{The weight of VPN in the micellar dispersion}}{\text{The weight of feeding VPN}} \times 100 \] (2)

Examination using transmission electron microscope (TEM)
Few drops of each NCs formulation were mounted on a carbon-coated grid and left for approximately 2 mins before examination using TEM model JEM-1230 (JOEL, Tokyo, Japan).

Incorporation of VPN-loaded NCs into thermosensitive ISG
ISG formulations loaded with NCs containing VPN equivalent to 0.25% w/v were developed using a combination of poloxamer 407 (22% w/v) and carbopol 940 (0.5 % w/v) by cold method. Selection of poloxamer and carbopol levels was based on the polymeric concentrations that achieve good ISG formulation characterization, which are in good agreement with our previously published work. Briefly, the calculated amount of poloxamer and carbopol was successively added to aqueous cold dispersion of VPN-loaded NCs at 4°C on a magnetic stirrer. The obtained dispersions were kept in the refrigerator (6°C) overnight. ISG formulation loaded with raw VPN (0.25% w/v) was also prepared, using the same method described above.
Characterization of VPN-loaded ISG formulations

Gelation temperature determination

The sol–gel temperature ($T_{\text{sol-gel}}$) for the prepared ISG formulations was evaluated by the tube inversion method previously published.\(^3\) Briefly, 1 mL of each formulation was placed in a glass vial and stored overnight in the fridge. Each ISG formulation was heated, with 1°C increments per step, in a thermostatic control heating water bath. The $T_{\text{sol-gel}}$ was recorded in the temperature range 20–30°C. The $T_{\text{sol-gel}}$ was considered as the temperature at which the ISG solution stopped flowing after complete inversion of the tube.

Determination of the pH

The pH of the prepared ISG formulations was determined using a calibrated pH meter using pH/mV/°C meter pH 11 series Oakton®, manufactured by Euteoh Instruments (Thermo Fisher Scientific, Singapore). Determinations were carried out in triplicate.

Evaluation of the mucoadhesive strength

The mucin particle method was utilized to study the mucoadhesiveness of the ISG formulations.\(^3\) Briefly, bovine mucin suspension was prepared by dispersing a known weight (10 mg) of the mucin powder in 100 mL phosphate buffer solution of pH 7.4. Then, a specified weight (150 mg) of the ISG formulation was added to 10 mL of the prepared mucin suspension with continuous shaking. After incubation for 48 hrs, zeta potential of each mixture was estimated using a Malvern Zetasizer Nano ZSP (Malvern Panalytical Ltd), and the obtained value was compared to that of the raw bovine mucin suspension. The mucoadhesiveness, interaction of the studied formulation components with mucin, was determined by identifying the change in zeta potential value.\(^3\)

Ex vivo permeation studies

The permeation of VPN, from the prepared ISG formulations loaded with either VPN-NCs or raw VPN, through excised bovine nasal mucosa was carried out using Franz diffusion cells, Microette Plus (Hanson Research, CA, USA). Fresh nasal mucosa was carefully excised from the nasal cavity of a bovine snout that was obtained from a local slaughterhouse. The prepared nasal mucosal samples were placed in the diffusion apparatus. The donor compartment was filled with 250 μL of the ISG formulation. Cells of the receptor compartments were filled with 7 mL phosphate buffer of pH 6.8. The temperature was kept at 34°C and stirring speed was adjusted at 400 rpm. Aliquots were automatically collected from the receptor media for 12 hrs at specified time intervals and replaced with fresh media. The concentration of VPN was determined using HPLC method described above. The experiment was performed in triplicate.

The permeation profiles of VPN were constructed by plotting the cumulative VPN amount permeated (Q) per unit area as a function of time. The steady-state flux ($J_{SS}$) was calculated for both the initial and the delayed permeation phases from the corresponding slopes. The permeability coefficients ($P_C$) were calculated by dividing the delayed flux by the initial drug load ($C_o$). The diffusivity (D) was also obtained by plotting the cumulative amount of VPN permeated versus the square root of time and applying Equation 3.

$$D = \left(\frac{\text{Slope}}{2C_0}\right)^2 \times \pi \quad (3)$$

Histological examination of nasal mucosa

To explore any change or modification in the intra-nasal tissues that arises due to IN application of the VPN-loaded TPGS-micelle ISG formulation, microscopic examination of the treated nasal epithelium was accomplished. The studied ISG formulation was applied on freshly separated excised bovine nasal mucosa for 12 hrs in the Franz diffusion cells as previously stated in the ex vivo permeation study. Following treatment, nasal mucosal samples were removed and stored in formalin (10%), dehydrated and finally embedded in paraffin wax. Samples were cut into 4-micron sections, stained with hematoxylin and eosin and Gomori’s Trichrome and examined using Nikon Eclipse 80i digital imaging light microscopy (Kanagawa, Japan). For comparative study, the control sample was also investigated. Each tissue sample was assessed for any sign of irritation, inflammation, and the appearance of epithelial and goblet cells.\(^4\)

Pharmacokinetic and brain tissue distribution after IN administration

The pharmacokinetics and brain tissue distribution of VPN following IN administration of ISG formulations containing either VPN-loaded TPGS-micelles or raw VPN was evaluated. The study was conducted in comparison with a marketed oral VPN tablet, Vinporal® 5 mg (Amriya Pharmaceutical Industries Company, Alexandria, Egypt),
to determine the relative bioavailability. The concentration of VPN in the brain was calculated using Equation 4.

\[
\text{VPN concentration in 1 ml homogenate} = \frac{\text{VPN concentration (ng/g)}}{\text{Total volume of homogenate}} \times \text{Average weight of rat brain (g)}
\]

Animal population
Male Sprague-Dawley rats, with an average weight of 260 g, were kept in a pathogen-free space in the Department of Pharmacology and Toxicology, Faculty of Pharmacy, King Abdulaziz University (KAU), Jeddah, KSA. The animal experimental protocol was revised and approved by the Animal Ethics and Animal Care Committee, Faculty of Pharmacy, KAU (Approval No. 1031439). The study fulfilled with the Declaration of Helsinki, the Guiding Principle in Care and Use of Animals (DHEW production NIH 80±23) and the “Standards of Laboratory Animal Care” (NIH distribution #85±23, reconsidered in 1985). Rats were divided into three groups (15 per group). Group I administered IN ISG formulation loaded with VPN-TPGS micelles; group II given IN ISG formulation containing raw VPN; group III administered oral marketed VPN tablet that was crushed and suspended in 0.25% sodium carboxymethyl cellulose solution. Each rat was administered a VPN dose of 10 mg/kg.

Sample collection
Animals were anesthetized and blood samples of 0.5 mL (n=6) were taken at different time points of 0.5, 1, 1.5, 2, 4, 6, 8, 12 and 24 hrs. For brain tissue samples, animals were euthanized by cervical dislocation, brain tissues (n=3) were harvested after 6, 12 and 24 hrs and stored at −80ºC. Brain tissues were homogenized in PBS. Plasma and brain tissue homogenate samples were treated and analyzed as described in the following section.

Chromatographic quantification of VPN
The concentrations of VPN in the plasma and brain tissue samples were analyzed by liquid chromatography-tandem mass spectrometry method. HPLC Agilent 1200 system equipped with Agilent 6420, triple quad mass spectrometer and controlled by Mass Hunter software was used. The separation was performed on a Nacheery Nagel, Nucleodur C18 column, 5 µm, 4.6×250 mm (Duren, Germany). The mobile phase comprised of 0.1% formic acid and acetonitrile (29:71, v/v) and the flow rate was adjusted at 0.5 mL/min. VPN and the internal standard (IS) Valsartan were detected in a single-ion monitoring (SIM) scan mode with positive ion detection. The ions used for the SIM detection were m/z 351.1 for VPN and m/z 436.1 for Valsartan.

Linearity and recoveries
Linearity of the assay method within a VPN concentration range of 200–800 pg/µL was verified with a regression coefficient (R²=0.9991). All the obtained results were within the acceptable criteria as previously stated in the recommended guidelines. The mean recovery of VPN was 102.2% at 200 pg/µL (LLOQ) and 97.5% at 800 pg/µL (ULOQ).

Sample extraction procedure
To a 200 µL of the plasma samples or brain tissue homogenate, 50 µL of Valsartan (IS) and 1 mL of acetonitrile were added. The resulting solution was thoroughly vortex-mixed for 10 s. After centrifugation at 5000 rpm for 5 mins, 5 µL of the supernatant was injected into the HPLC system for analysis. The concentration of VPN in the unknown samples was calculated from the regression equation obtained from the constructed calibration curve.

Pharmacokinetic treatment
The pharmacokinetic parameters of VPN in the collected plasma data were assessed using non-compartmental pharmacokinetic treatment utilizing Kinetica™ software (version 4, Thermo Scientific, MA, USA). The maximum plasma VPN concentration (Cmax), time to reach maximum VPN plasma concentration (tmax), area under the plasma VPN concentration time curve from zero to the last measurable VPN concentration (AUC0–), area under the plasma VPN concentration time curve from zero to infinity (AUC0–α), mean residence time (MRT), the elimination rate constant, elimination half-life and total body clearance were measured. The data were expressed as the mean ± SD.

Statistical analysis of the data
The data obtained was analyzed using GraphPad Prism 6 (GraphPad Software, San Diego, CA) software. Two-way ANOVA followed by Tukey’s multiple comparisons test was used to assess the significance of the difference between the investigated groups.

Results and discussion
Evaluation of the prepared VPN-loaded lipid-based NCs
Table 1 shows the results of the particle size for the prepared NCs formulations. VPN-loaded TFs revealed
the largest size (590±47 nm), while VPN-loaded TPGS-
micelles displayed the smallest size (13±2 nm). 
Furthermore, the polydispersity index of the prepared 
VPN-loaded lipid-based NCs was between 0.444 and  
0.494, which indicates acceptable size distribution. TEM 
images (Figure 1) showed a spherical particle morphology 
for all the prepared colloidal dispersion. The obtained 
images confirmed the uniformity in size distribution that 
were comparable with the data obtained by the Zetasizer 
Nano ZSP. Due to its content of the charge-inducing agent 
(DCP), the colloidal dispersion of VPN-loaded Peg-Lips 
showed the highest stability with a zeta potential value of 
−52.27±0.80 mV. This Peg-Lips displayed the lowest per-
centage of VPN entrapped (59.05%), whereas the remain-
ing NCs formulations exhibited high VPN EE that ranged 
from 89.01% to 100%. TPGS-micelles demonstrated the 
highest EE of about 100% which could be attributed to the 
nature of the drug loaded. Yang et al reported high drug 
encapsulation efficiency for TPGS-based fabricated 
NCs.43 Zhu et al also stated 85–95% EE for docetaxel 
vitamin E TPGS NPs.44 Similarly, Muthu et al mentioned 
an encapsulation efficiency up to 84.30±0.80% for doce-
taxel-loaded vitamin E TPGS micelles.45 The prepared 
TFs and SLNs formulations showed high drug entrapment 
of 97.01% and 89.34%, respectively. The Peg-Lips dis-
played the lowest drug EE of 59.05% which is in a good 
accordance with the previously reported EE results of the 
same formulation.30

Evaluation of the prepared VPN-loaded 
ISG formulations
Poloxamer 407 (22% w/v) and carbopol 940 (0.5% w/v) 
combination was found to be the optimum concentration 
for the polymeric solution to form ISG formulations 
loaded with different NCs. Addition of hydrophilic poly-
mer such as carbopol 940 to poloxamer 407 enforces the 
mechanical strength and overcomes the possibility of the 
gel erosion.46

The sol–gel transition temperature of the colloidal dis-
persions ranged from 25.33±1.53°C for TFs-ISG to 30.00 
±1.00°C for TPGS-micelles-ISG. It has been previously

![Figure 1](https://www.dovepress.com/)

**Figure 1** Transmission electron microscope images of the prepared lipid-based nanocarriers.
reported that an ISG system with a sol–gel transition temperature higher than but close to 25°C is anticipated to be highly viscous at room temperature, the favorable sol–gel transition temperature should be close to but not exceed 30°C. In addition, the reported temperature in the human nose ranged from 30.2±1.7°C to 34.4±1.1°C, and the sol–gel transition temperature of the prepared formulations ensures the suitability of their application on the nasal mucosa. Our results revealed that the pH of the formulations ranged from 5.54±0.02 to 7.06±0.02. This pH range indicated that no irritancy is expected from the formulations following application on the nasal mucosa. All the prepared ISG formulations revealed the presence of mucoadhesive properties as indicated by the change in zeta potential value for all the studied ISG formulation when compared with raw bovine mucin suspension (data not shown). The prepared mucin suspension showed a negative zeta potential value of −9.88 mv. This value is attributed to ionization of the mucin carboxyl groups as previously stated. A marked decrease in the mucin zeta potential value was noticed upon mixing with the prepared ISG formulations. This finding is an indication of the formulation mucoadhesive properties brought about by the interaction between mucin and the polymeric ISG formulation.

**Ex vivo permeation studies**

Table 2 shows the permeation parameters of VPN from different NCs-loaded ISG formulations compared with raw VPN-loaded ISG across the bovine nasal mucosa. The permeation studies showed that higher permeability coefficient, diffusion coefficient and maximum amount of drug permeated (D_max) were noticed from VPN-loaded Peg-Lips-ISG followed by VPN-loaded TPGS-micelles-ISG which is an indication of the ability of these NCs to penetrate the nasal mucosa to a greater extent when compared with the other NCs-loaded ISG formulations and the raw VPN-loaded ISG. Also, the Peg-Lips-ISG and TPGS-micelles-ISG formulation recorded the highest steady-state permeation fluxes (Jss) of 0.7913 and 0.7258 µg/cm².h, respectively. While their permeability coefficients (Kc) reaching 0.0012 and 0.0011 cm/h, respectively, indicating a general better permeation results than other NC formulations (Figure 2). The highest amount of drug diffused (639.029 µg) with the lowest percentage of VPN permeated over 12 hrs (58.38%) reflect the superiority of TPGS-micelles-ISG in the diffusivity and in sustaining the permeation over the other NCs formulations. The lipophilic nature and the small particle size of micelles could explain this nasal permeation enhancement. Another reason for this finding encompasses the fact that the formation of occlusive monolayer film on a large surface area of the mucous membrane diminishes the loss of moisture due to evaporation, which can enhance the drug permeation. Additionally, the surfactant activity of TPGS can fluidize or loosen the intercellular lipid layer of the nasal mucosa and so enhances the drug permeation. Also, the enhanced permeability of TPGS-micelles might be attributed to the P-gp inhibitory effects which has been approved by the FDA.

**Assessment of nasal mucosa irritancy upon application of TPGS-micelles-ISG formulation**

Figure 3 demonstrates the histological photomicrographs of the nasal mucosa after 12 hrs of treatment with

Note: 0.5% Carbopol 940 and 22% poloxamer 407 were used in each ISG formulation.

Abbreviations: VPN, vinpocetine; NCs, nanocarriers; ISG, in situ gelling; SLNs, solid lipid nanoparticles; TPGS, D-α-tocopherol polyethylene glycol 1000 succinate; TFs, tranfersomes.
VPN-loaded TPGS-micelle ISG (Figure 3A) and the normal (untreated) nasal mucosa (Figure 3B). No signs of irritancy or inflammation have been observed on the treated nasal tissue. Also, the normal appearance of both ciliated respiratory epithelium and goblet cells have been noticed. Therefore, the poloxamer-based ISG formulation is considered safe to use with respect to nasal administration which is in good accordance with a previous study.  

Brain tissue distribution and pharmacokinetics
To evaluate the in vivo effectiveness of the developed VPN-loaded TPGS-micelles ISG formulation after IN administration to male Sprague Dawley rats, the brain distribution and the pharmacokinetics were studied and compared to raw VPN-loaded ISG formulation and a marketed oral VPN tablet. The concentration of VPN
in the rat’s brain tissue at different time points is shown in Figure 4. The nasal administration of VPN-loaded TPGS-micelles ISG formulation exhibited approximately 10-fold higher in brain tissue than the corresponding raw VPN-loaded ISG formulation and the marketed oral VPN tablets after 6 hrs. The plasma concentration versus time profiles after IN administration of VPN-loaded TPGS-micelles ISG and the raw VPN-loaded ISG as well as the oral administration of VPN tablet is shown in Figure 5. The pharmacokinetic parameters for each group are summarized in Table 3. In the brain tissue, rats administered VPN-loaded TPGS-micelles-ISG showed a much higher VPN concentration profile in comparison to that received oral tablet which displayed irrelevant difference with rats administered raw VPN-loaded ISG (Figure 4). It was reported that the human nasal respiratory and olfactory mucosa contain an efflux transporter known as P-gp which plays an important role in preventing actively the drugs influx from the nasal membrane. Therefore, the incorporation of P-gp inhibitor as TPGS in the micelles could influence the penetration of the blood–brain barrier and enhance the brain uptake with higher concentrations after IN administration. This finding indicates that development of VPN in the form of TPGS-micelles ISG played a major role in the enhancement of the drug nasal absorption and results in enhanced drug brain circulation using the TPGS micelles.

Finally, the developed thermosensitive ISG loaded with TPGS micelles exhibited enhancement in the pharmacokinetic parameters with significant high relative bioavailability. VPN-loaded TPGS-micelles ISG showed a significant increase in VPN $C_{\text{max}}$ by 2.2- and 2.6-fold when compared with the oral VPN tablet and the raw VPN-loaded ISG, respectively. All formulations reached...
Table 3 Pharmacokinetic parameters ± SD of VPN following the intranasal administration of a single dose (10 mg/kg) of VPN-loaded TPGS-micelles-ISG in comparison with the intranasal administration of raw VPN-loaded ISG and the oral administration of VPN tablet by rats.

| Relative bioavailability (%)| 100.0          | 159.183                     | 84.116            |

Note: *Significant difference at P<0.05 (unpaired t-test).

Abbreviations: VPN, vinpocetine; ISG, in situ gel; AUC, area under the time-concentration curve; C_{max}, maximum plasma concentration; K_{el}, elimination rate constant; MRT, mean residence time; t_{max}, time to reach C_{max}; TPGS, D-α-tocopherol polyethylene glycol 1000 succinate.

the maximum plasma concentration after 2 hrs with no significant difference in the elimination half-life (P-value >0.05). The relative bioavailability of VPN from TPGS-micelles ISG was 159.183% compared with the oral marketed tablet. Whereas, the bioavailability of VPN was reduced to 84.116% after IN administration of the raw VPN-loaded ISG when compared with the marketed tablet. This finding confirms the superiority of TPGS-micelles in the brain delivery of VPN via administration of thermosensitive IN ISG although a long-term study is required.

Conclusion
Successful development of VPN-loaded TPGS-micelles ISG formulation could be considered a key solution for VPN short half-life and poor bioavailability. Moreover, the prepared formulation enhanced the drug brain delivery and was superior to the marketed drug oral product. So, this formulation could represent a good alternative for the currently available marketed drug products.
