B.R.S. renormalisation of some on-shell closed algebras of symmetry transformations :
2) N=2 and 4 supersymmetric non-linear $\sigma$ models

Guy Bonneau *

November 11, 2017

Abstract

We analyse with the algebraic, regularisation independant, cohomological B.R.S. methods, the renormalisability of torsionless N=2 and N=4 supersymmetric non-linear $\sigma$ models built on Kähler spaces. Surprisingly enough with respect to the common wisdom, in the case of N=2 supersymmetry, we obtain an anomaly candidate, at least in the compact Kähler Ricci-flat case. If its coefficient does differ from zero, such anomaly would imply the breaking of global N=2 supersymmetry and get into trouble some schemes of superstring compactification as such non-linear $\sigma$ models offer candidates for the superstring vacuum state.

In the compact homogeneous Kähler case, as expected, the anomaly candidate disappears.

The same phenomena occurs when one enforces N=4 supersymmetry : in that case, we obtain the first rigorous proof of the expected all-orders renormalisability -“in the space of metrics”- of the corresponding non-linear $\sigma$ models.

1 Introduction

Supersymmetric non-linear $\sigma$ models in two space time dimensions have been considered for many years to describe the vacuum state of superstrings [1], [2]. In particular Calabi-Yau spaces, i.e. 6 dimensional compact Kähler Ricci-flat Riemannian manifolds [3], appear as good candidates in the compactification of the 10 dimensional superstring to 4 dimensional flat Minkowski space; indeed, the conformal invariance of the 2.d, $N = 2$ supersymmetric non-linear $\sigma$ model (the fields of which are coordinates on this compact manifold) is expected to hold to all orders of perturbation theory [4].

However explicit calculations to 4 or 5 loops [5] and, afterwards, general arguments [6] show that the $\beta$ functions might be different from zero. But, as argued in my recent review [7], at least two problems obscure these analyses: first, the fact that the quantum theory is not sufficiently defined by the Kähler Ricci-flatness requirement; second, the use of “dimensional reduction” [8] or of harmonic superspace [9] in actual explicit calculations and general arguments. Then, we prefer to analyse these models using the B.R.S., algebraic, regularization free cohomological methods.

Moreover, the quantisation of extended supersymmetry raises the difficulty of an “on-shell” formalism. Indeed, if one leaves aside harmonic superspace where firm rules for quantisation are not at hand, on the contrary of ordinary superspace [11], one has to deal with (super)symmetry transformations that are non-linear and closes only on-shell. This problem was adressed in ref. [12] by O. Piguet and K. Sibold for the Wess-Zumino model as a “toy-model” and, in a still incomplete way, by P. Breitenlohner and D. Maison [3] for supersymmetric Yang-Mills in the Wess-Zumino gauge; in the first paper of this series [14], hereafter refered to as (I), we analysed the $d=2$, $N=1$ supersymmetric non-linear $\sigma$ model without auxiliary fields.

In the second paper of this series, we adress ourselves the question of the all-orders renormalisability of extended supersymmetric ($N = 2$, 4) non-linear $\sigma$ models in two space time dimensions. Of course, we are only interested here in the renormalisation of the supersymmetry transformations: as discussed by Friedan [13], the action of a non-linear $\sigma$ model may be identified with a distance on a Riemannian manifold $\mathcal{M}$, the metric depending a priori on an infinite number of parameters. One then speaks of “renormalisability in the space of metrics” or “à la Friedan”. When there exist extra isometries, for example in the case of the non-linear $\sigma$ models on coset spaces (homogeneous manifolds), the number of such physical parameters becomes finite and we have proved the U.V. renormalisability of these isometries in the purely bosonic case in [16], as well as in the $N=1$ supersymmetric extension in (I). The present work gives the necessary extended-supersymmetric generalisations. On the other hand, in the generalised non-linear $\sigma$ models à la Friedan, our aim is the proof that no extra difficulty occurs in their supersymmetric extension.

We shall use $N=1$ superfields, which is allowed by the general superspace quantisation methods established by Piguet and Rouet who in particular demonstrated the Quantum Action Principle in that context [11], and the very results of (I), proving that $N=1$ supersymmetry is all-orders renormalisable. The classical theory was defined in (I), so here we only recall in sub-

---

1 The regularisation through dimensional reduction suffers from algebraic inconsistencies and the quantisation in harmonic superspace does not rely on firm basis, due to the presence of non-local singularities (in the harmonic superspace) [10].

2 i.e. a subtraction algorithm insuring the locality of the counterterms [10].
section 2.1 the results needed for the following. Due to the non-linearity of the supersymmetry transformations in a general field parametrisation (i.e. coordinate system on the manifold), we shall use a gradation (according to the spectral sequences method \cite{17}) in the number of fields, ghosts and their derivatives. As a matter of facts, we find it convenient to use two successive gradations, one in the number of extra supersymmetries, the second one with respect to the number of fields. The “filtrations”, as well as the lowest order nilpotent Slavnov operators: $S_{L}^{0}$ - corresponding in fact to N=2 supersymmetry -, and $S_{L}^{00}$ - corresponding to the zero field approximation of $S_{L}^{0}$ -, are defined in subsection 2.2. As in \cite{16} and (I), the cohomology of $S_{L}^{00}$ will give the main information. In Section 3, we analyse the cohomology of $S_{L}^{00}$ and in Section 4 the one of $S_{L}^{0}$, i.e. at that point we are concerned with the special case of N=2 supersymmetric non-linear $\sigma$ models, and we find a non trivial cohomology in the anomaly sector. Subsection 4.4 is then devoted to a discussion of this N=2 case and our main result is that, surprisingly enough with respect to the common wisdom \cite{18}, there exists a possible anomaly for global supersymmetry in 2 space-time dimensions \cite{21}, at least for torsionless compact Kähler Ricci-flat manifolds (i.e. special N=2 supersymmetric models). We also prove that this anomaly disappears when the manifold $\mathcal{M}$ is an homogeneous one, i.e. when one deals with N=2 supersymmetric non-linear $\sigma$ models on coset spaces. Section 5 then constructs the cohomology space of the complete $S_{L}$ operator, with the essential result of the all orders renormalisability of N=4 supersymmetric non-linear $\sigma$ models. A discussion of our results is presented in the concluding Section.

2 The classical theory and the Slavnov operator

In (I) we obtained the classical action and the linearised Slavnov operator that describes N=4 supersymmetry and hereafter we summarize the essential results.

2.1 The classical theory and the Slavnov identity

We consider d=2, N=4 supersymmetric non-linear $\sigma$ models in N=1 superfields $\Phi^{i}(x, \theta)$ (i, j,.. = 1,2,..4n). In light-cone coordinates and in the absence of torsion, the non-linear N=4 supersymmetry transformations write :

$$\delta \Phi^{i} = J^{i}_{A,j}(\Phi)[\epsilon_{A}^{+} D_{+}^{j} \Phi^{j} + \epsilon_{A}^{-} D_{-}^{j} \Phi^{j}] , \quad A = 1, 2, 3. \quad (1)$$

where the covariant derivatives are

$$D_{\pm} = \frac{\partial}{\partial \theta^{\pm}} + i \theta^{\pm} \partial_{\pm}$$

and satisfy

$$\{D_{\pm}, D_{\mp}\} = 2i \partial_{\pm} \quad \{D_{+}, D_{-}\} = 0 \quad (2)$$

\footnote{Notice also that recent works of Brandt \cite{19} and Dixon \cite{20} show the existence of new non-trivial cohomologies in supersymmetric theories.}
As is well known (see for example ref. [22]), N=4 supersymmetry needs the $J_{A,j}^i(\Phi)$ to be a set of anticommuting integrable complex structures according to:

$$J_{A,j}^i(\Phi)J_{B,k}^j(\Phi) = -\delta_{AB}\delta^i_k + \epsilon_{ABC}J_{C,k}^i(\Phi)$$  \hspace{1cm} (3)

and the invariance of the action $A^{inv.} = \int d^2x d^2\theta g_{ij}[\Phi]D_+^i\Phi^j D_-^j\Phi^j$ needs the target space to be hyperkähler:

* the metric $g_{ij}$ is hermitic with respect to each complex structure

$$J_{A,j}^i = J_{A,k}^i g^{kj} = -J_{A,j}^i ; \quad J_{A,ij} = J_{A,ik}g_{kj} = -J_{A,j}^i$$

* the $J_{A,j}^i$ are covariantly constant

$$D_k J_{A,j}^i \equiv \partial_k J_{A,j}^i + \Gamma_{kl}^i J_{A,j}^l - \Gamma_{kj}^l J_{A,l}^i = 0$$

where $\Gamma_{kl}^i$ is the (symmetric) connexion with respect to the metric $g_{ij}$. In the B.R.S. approach [23], the supersymmetry parameters $\epsilon^i_A$ are promoted to constant, commuting Faddeev-Popov parameters $d_A^\pm$ and an anticommuting classical source $\eta_i(x)$ for the non-linear field transformation [24] is introduced in the classical action [24]. Then, the total effective action [24] is:

$$\Gamma^{class.} = A^{inv.} + \int d^2x d^2\theta \{ \eta_i J_{A,j}^i(\Phi)[d_A^+D_+\Phi^j + d_A^-D_-\Phi^j] - \frac{1}{2}\epsilon_{ABC}\eta_i J_{C,k}^i(\Phi)d_A^+d_B^- \}$$  \hspace{1cm} (4)

The terms quadratic in the sources are needed as a consequence of the only on-shell closedness of the N=4 supersymmetry algebra [24](1).

The Slavnov identity writes:

$$S\Gamma^{class.} \equiv \int d^2x d^2\theta \frac{\delta \Gamma^{tot.}}{\delta \eta_i(x, \theta)} \frac{\delta \Gamma^{tot.}}{\delta \Phi^j(x, \theta)} = \int d^2x d^2\theta[(d_A^+)^2(\eta_i i \partial_+ \Phi^k) + (d_A^-)^2(\eta_i i \partial_- \Phi^k)] .$$  \hspace{1cm} (5)

This is a not trivial result as in that N = 4 case, no finite set of auxiliary fields does exist.

As is by now well known (for example see [7] or [10]), in the absence of a consistent regularisation that respects all the symmetries of the theory, the quantum analysis directly depends on the cohomology of the nilpotent linearised Slavnov operator:

$$S_L = \int d^2x d^2\theta \left[ \frac{\delta \Gamma^{class.}}{\delta \eta_i(x, \theta)} \frac{\delta}{\delta \Phi^j(x, \theta)} + \frac{\delta \Gamma^{class.}}{\delta \Phi^j(x, \theta)} \frac{\delta}{\delta \eta_i(x, \theta)} \right]$$  \hspace{1cm} (6)

4 As a matter of facts, it is sufficient to have 2 anticommuting integrable complex structures: then, the product $J_{A,j}^iJ_{A,k}^j$ offers a third complex structure.

5 As one is only concerned by integrated local functionals - i.e. trivially translation invariant ones -, we forget about the linear translation operators $P_{\pm} = i\partial_{\pm}$ to which anticommuting Faddeev-Popov parameters $p_{\pm}$ should be associated, and do not add in $\Gamma^{class.}$ of equ.(4) the effect of translations on the fields $\Phi^j$.

6 In the absence of torsion, there is a parity invariance

$$+ \rightarrow - , \quad d^2x \rightarrow d^2x , \quad d^2\theta \rightarrow -d^2\theta , \quad \Phi^i \rightarrow \Phi^i , \quad \eta_i \rightarrow -\eta_i .$$

Moreover, the canonical dimensions of $[d^2x d^2\theta]$, $[\Phi^i]$, $[d_A^\pm]$, $[D_\pm]$, $[\eta_i]$ are -1, 0, -1/2, +1/2, +1 respectively and the Faddeev-Popov assignments +1 for $d_A^\pm$, -1 for $\eta_i$, 0 for the other quantities.

7 For simplicity, no mass term has been added here as here we are only interested in U.V. properties.
in the Faddeev-Popov charge +1 sector [absence of anomalies for the supersymmetry] and 0 sector [number of physical parameters and stability of the classical action through radiative corrections]. Notice that the Slavnov operator (6) is unchanged under the following field and source reparametrisations:

\[ \Phi^i \rightarrow \Phi^i + \lambda W^i[\Phi], \quad \eta_i \rightarrow \eta_i - \lambda \eta_k W^k_i[\Phi], \]

where \( W^i[\Phi] \) is an arbitrary function of the fields \( \Phi(x, \theta) \) and a comma indicates a derivative with respect to the field \( \Phi^i \). Under this change, the classical action (4) is modified:

\[ \Gamma_{\text{class.}} \rightarrow \Gamma_{\text{class.}} + \lambda S_L \int d^2 x d^2 \theta \eta_i W^i[\Phi] \quad (7) \]

but the Slavnov identity is left unchanged as

\[ S[\Gamma_{\text{class.}} + \lambda S_L \Delta] \equiv S \Gamma_{\text{class.}} + \lambda S_L [S_L \Delta] = S \Gamma_{\text{class.}}. \quad (8) \]

The quantisation of this theory will be studied in the next Sections, using the same algebraic cohomological methods as in the first paper of this series (I). It will be convenient to separate the 3 extra supersymmetries into the one corresponding to \( J_3 \) and the 2 others to \( J_\alpha, \alpha=1,2 \), \( i.e. \) to separate the N=2 supersymmetric case from the N=4 one. In the same way, one splits the linearised Slavnov operator into 3 parts according to their number of ghosts \( d^\pm_\alpha \):

\[ S_L = S^0_L + S^1_L + S^2_L \]

\[ (S^0_L)^2 = S^0_L S^1_L + S^1_L S^0_L = 0 \]

\[ S^0_L \delta \Phi^i \]

\[ = \int d^2 x d^2 \theta \{ J^i_j (d^+ D_+ \Phi^j + d^- D_- \Phi^j) + \frac{\delta}{\delta \Phi^i} \} \]

\[ + \{ \delta A^\text{inv.}_{\Phi^i} + \eta_k (J^k_{i,j} - J^k_{j,i}) (d^+ D_+ \Phi^j + d^- D_- \Phi^j) + J^i_j (d^+ D_+ \eta_i + d^- D_- \eta_i) \} \]

which does not change the number of ghosts \( d^\pm_\alpha \), will play a special role. Moreover, notice that the cohomology of \( S^0_L \) corresponds to the special N=2 supersymmetric case.

### 2.2 The filtration and the operator \( S^0_L \)

In the presence of highly non-linear Slavnov operators such as in (6), as recalled in (I), it is technically useful to “approximate” the complete \( S^0_L \) operator by a simpler one \( S^{00}_L \) through a suitably chosen “filtration”( ghost number preserving counting operation) [7]. As it does not change this number, \( S^{00}_L \), the nihilpotent lowest order part of \( S^0_L \), will play a special role. Here, we take as counting operator the total number of fields \( \Phi^i(x, \theta) \) and their derivatives. Then:

\[ S^0_L = S^{00}_L + S^{01}_L + S^{02}_L + \ldots \equiv S^{00}_L + S^0_L, \quad (S^{00}_L)^2 = 0 \]

\[ S^{00}_L = J^i_j(0) \int d^2 x d^2 \theta \left\{ (d^+ D_+ \Phi^j + d^- D_- \Phi^j) \frac{\delta}{\delta \Phi^i} + (d^+ D_+ \eta_i + d^- D_- \eta_i) \frac{\delta}{\delta \eta^j} \right\} \quad (10) \]

---

8 In the following, we then omit the index 3 of the complex structure \( J_3 \) as well as the one of the ghost \( d^\pm_3 \).
As explained in refs.([17],[16]), when $S_L^{00}$ has no cohomology in the Faddeev-Popov charged sectors, the cohomology of the complete $S_L^0$ operator in the Faddeev-Popov sectors of charge 0 and +1 is isomorphic to the one of $S_L^{00}$ in the same sectors. The extension to the case where $S_L^{00}$ has some non-trivial cohomology was discussed in the appendix of (I) (see also the original papers [17],[16] and [25]).

Then, in the next Section, we shall determine the cohomology space $S_L^{00}$ of $S_L^{00}$ in the Faddeev-Popov sectors of charge -1, 0 and +1.

3 The cohomology of $S_L^{00}$

The most general functional in the fields, sources, ghosts and their derivatives, of a given Faddeev-Popov charge, is built using Lorentz and parity invariance and power counting (see footnote 6).

3.1 The Faddeev-Popov negatively charged sectors

Due to dimensions and Faddeev-Popov charge assignments, dimension zero integrated local polynomials in the Faddeev-Popov parameters, fields, sources and their derivatives have at least a Faddeev-Popov charge -1:

$$
\Delta_{[-1]} = \int d^2 x d^2 \theta \eta_i V^i[\Phi].
$$

(11)

Then there is no Faddeev-Popov charge -1 coboundaries, so the cohomology of $S_L^{00}$ in that sector is given by the cocycle condition:

$$
S_L^{00} \Delta_{[-1]} = 0 \iff J^i_j(0)V^k_i = J^k_i(0)V^i_j
$$

(12)

This condition, when expressed in a coordinate system adapted to the complex structure $J^i_j[\Phi]$ ($i \equiv (a, \bar{a})$, $\Phi^i \equiv (\phi^a, \bar{\phi}^\bar{a})$ : $J^a_b = i \delta^a_b$, $J^{\bar{a}}_{\bar{b}} = -i \delta^\bar{a}_{\bar{b}}$, $J^a_{\bar{b}} = J^{\bar{b}}_a = 0$), means that $V^i[\Phi]$ is a contravariant analytic vector : $V^a = V^a[\phi^a]$, $V^{\bar{a}} = V^{\bar{a}}[\bar{\phi}\bar{a}]$.

Let us now turn to the Faddeev-Popov neutral charge sector.

3.2 The Faddeev-Popov 0 charge sector

Here, one decomposes the set of integrated local polynomials in the Faddeev-Popov parameters, fields, sources and their derivatives with respect to their number of ghosts $d^\pm_{\alpha, N_{\alpha}}$.

$$
\begin{align*}
\Delta_{[0]}^0 & = \int d^2 x d^2 \theta \left\{ t_{ij}[\Phi] D_+ \Phi^i D_- \Phi^j + \eta_i U^i_j[\Phi] (d^+_a D_+ \Phi^j + d^-_a D_- \Phi^j) \right\} \\
\Delta_{[0]}^1 & = \int d^2 x d^2 \theta \left\{ \eta_i U^i_j[\Phi] (d^+_a D_+ \Phi^j + d^-_a D_- \Phi^j) + \eta_j \eta_j (d^+_a d^-_a - d^-_a d^+_a) S^i_{a j} [\Phi] \right\} \\
\Delta_{[0]}^2 & = d^+_a d^-_\beta \int d^2 x d^2 \theta \eta_i \eta_j S^i_{a j} [\Phi]
\end{align*}
$$

(13)

In particular, the cohomology of $S_L^{00}$ in the Faddeev-Popov -1 sector restricts the dimension of the cohomology of $S_L^0$ in the 0 charge sector when compared to the one of $S_L^{00}$. 
where, due to parity invariance (footnote 6), \( t_{ij} \) (resp. \( S_{ij}^\alpha, S_{[\alpha\beta]}^{ij} \)) are symmetric (resp. skew-symmetric) in (i,j). Coboundaries being given by \( S^{00}_L\Delta_{-1}[arbitrary \ V^i(\Phi)] \), the analysis of the cocycle condition \( S^{00}_L\Delta_{[0]} = 0 \) successively gives:

### 3.2.1 \( N_{da} = 0 \)

\[
\Delta^0_{[0]} = \Delta^0_{[0]}[t_{ij}(\Phi)] + S^{00}_L\Delta_{-1}[V^i(\Phi)] \quad ; \quad \Delta^0_{[0]}[t_{ij}] = \int d^2x d^2\theta t_{ij}[\Phi] D_+ \Phi^i D_- \Phi^j
\]

where the tensor \( t_{ij} \) which occurs in the anomalous part is constrained by:

\[
\begin{align*}
a) & \quad J_j^i(0)t_{ik} + t_{ji}J^k_i(0) = 0, \\
b) & \quad J_j^i(0)[t_{kj,i} - t_{il,k}] - (j \leftrightarrow k) = 0.
\end{align*}
\]

The absence of source dependent non-trivial cohomology means that, up to a field redefinition (see (28)), the complex structure \( J^i_j \) is left unchanged through radiative corrections. Moreover, condition (38a) means that the metric \( g_{ij} + ht_{ij} \) remains hermitian with respect to the complex structure \( J^i_j \), whereas (38b) expresses the covariant constancy of \( J^i_j \) with respect to the covariant derivative with a connexion corresponding to the metric \( g_{ij} + ht_{ij} \). These are precisely the expected conditions for the stability of N=2 supersymmetry.

### 3.2.2 \( N_{da} = 1 \)

\( S^{00}_L\Delta^1_{[0]} = 0 \) gives (no coboundaries exist in that sector):

\[
U^i_{\alpha,j} = 0, \quad \Delta^1_{[0]} = \Delta^0_{[0]}[S^i_{\alpha j}(\Phi)] = \int d^2x d^2\theta \eta_i \eta_j (d^+_\alpha d^- - d^-_\alpha d^+) S^i_{\alpha j}(\Phi),
\]

where the tensor \( S^i_{\alpha j} \) which occurs in the anomalous part is constrained by:

\[
\begin{align*}
a) & \quad J^i_k(0)S^{kj}_{\alpha} + S^{ki}_{\alpha} J^j_k(0) = 0, \\
b) & \quad J^i_k(0)S^i_{\alpha,n} - J^i_n(0)S^{nj}_{\alpha,k} = 0,
\end{align*}
\]

\( i.e., \) using the same adapted coordinate system as above, is a pure contravariant analytic skew-symmetric tensor (\( i.e. \) \( S^{[ab]}_{\alpha} = S^{[ab]}_{\alpha}(\phi^e) \), \( S^{[\alpha\beta]}_{\alpha} = S^{[\alpha\beta]}_{\alpha}(\bar{\phi}^e) \), the other components vanish).

### 3.2.3 \( N_{da} = 2 \)

\( S^{00}_L\Delta^2_{[0]} = 0 \) gives (no coboundaries exist in that sector):

\[
\Delta^2_{[0]} = \Delta^0_{[0]}[S^i_{\alpha j}^{ij}(\Phi)] = d^+_\alpha d^-_\beta \int d^2x d^2\theta \eta_i \eta_j S^i_{\alpha j}(\Phi)
\]

where the tensor \( S^i_{[\alpha\beta]} \) which occurs in the anomalous part is constrained by:

\[
\begin{align*}
a) & \quad J^i_k(0)S^{kj}_{[\alpha\beta]} + S^{ki}_{[\alpha\beta]} J^j_k(0) = 0, \\
b) & \quad J^i_k(0)S^i_{[\alpha\beta],n} - J^i_n(0)S^{nj}_{[\alpha\beta],k} = 0,
\end{align*}
\]

\( i.e., \) using the same adapted coordinate system as above, is a pure contravariant analytic skew-symmetric tensor.

Finally, let us consider the Faddeev-Popov charge +1 sector.
3.3 The Faddeev-Popov +1 charge sector

Here also, one decomposes the set of integrated local polynomials in the Faddeev-Popov parameters, fields, sources and their derivatives with respect to their number of ghosts $d^+_\alpha$, $N_{d\alpha}$.

3.3.1 $N_{d\alpha} = 0$

$\Delta^0_{[+1]}$ depends on 8 tensors:

$$\Delta^0_{[+1]} = \int d^2 x d^2 \theta \{ (d^+) (d^-)^2 \eta_i \eta_j \eta_k t^{[ijk]} + d^+ d^- [\eta_i \eta_j t^{[ij]} (d^+ D_+ \Phi^n - d^- D_- \Phi^n) + \eta_i s^{(ij)}(d^+ D_+ \eta_j - d^- D_- \eta_j)]
+ d^+ d^- \eta_k t^k_{[ij]} D_+ \Phi^i D_- \Phi^j 
+ \eta^2 t^k_{[ij]} D_+ \Phi^i D_- \Phi^j + t^k_{[ij]} (D_+)^2 \Phi^j 
+ d^+ t_i^{[ij]} n D_+ \Phi^i D_+ \Phi^j D_- \Phi^n + s_2 (ij) D_- D_+ \Phi^i D_- \Phi^j 
- d^- (t_i^{[ij]} n D_+ \Phi^i D_- \Phi^j D_+ \Phi^j + s_2 (ij) D_- D_+ \Phi^i D_- \Phi^j) \} \tag{20}$$

where, due to the anticommuting properties of $\eta_i$ and $D_\pm \Phi^i$ and to the integration by parts freedom, the tensors $t^{[ijk]}$, $t^i_{[ij]} n$, $t^a_{[ij]}$, $t^n_{[ij]}$, $t_i^{[ij]} n$ are skew-symmetric in $i$, $j$, $k$, and $s_1^{(ij)}$, $s_2 (ij)$ symmetric in $i$, $j$. Here and in the following, the symmetry (resp. antisymmetry) properties of the involved tensors in the exchange $i$ to $j$ are indicated by parenthesis $(ij)$ (resp. brackets $[ij]$).

Coboundaries being given by $S^0_L \Delta^0_{[0]}$ [arbitrary $(t_i^{[ij]} \Phi, U_j^{[ij]} \Phi)$], the analysis of the cocycle condition $S^0_L \Delta^0_{[+1]} = 0$ leads to:

$$\Delta^0_{[+1]} = \int d^2 x d^2 \theta t^{[ijk]}(\Phi) (d^+) (d^-)^2 \eta_i \eta_j \eta_k \tag{21}$$

where the skew-symmetric tensor $t^{[ijk]}(\Phi)$ which occurs in the anomalous part is constrained by:

$$a) \quad J_n^i(0) t^{[njk]} \quad \text{is } i, j, k \text{ skew - symmetric,}$$

$$b) \quad J_n^i(0) t^{[njk]} = J_m^i(0) t^{[mjk]} \tag{22}$$

Using the same adapted coordinate system as above, condition (22a) means that the tensor $t^{[ijk]}$ is a pure contravariant skew-symmetric tensor (i.e. $t^{[abc]}$, $t^{[\bar{a} \bar{b} \bar{c}]} \neq 0$ , the other components vanish) whereas (22b) means that it is analytic (i.e. $t^{[abc]} = t^{[abc]}(\bar{\phi}^d)$, $t^{[\bar{a} \bar{b} \bar{c}]} = t^{[\bar{a} \bar{b} \bar{c}]}(\bar{\phi}^d)$). In particular, due to the vanishing of $t^{[abc]}$, such tensor cannot be a candidate for a torsion tensor on a Kähler manifold [26].

As a first result, this proves that if the manifold $M$ has a complex dimension smaller than 3, there is no $N_{d\alpha} = 0$ anomaly candidate.

3.3.2 $N_{d\alpha} = 1$

With an expansion similar to the one of $\Delta^0_{[+1]}$, $\Delta^1_{[+1]}$ now depends on 11 tensors:

$$\Delta^1_{[+1]} = d^+_\alpha \int d^2 x d^2 \theta \{ (d^+) (d^-)^2 \eta_i \eta_j \eta_k t^{[ijk]}_\alpha \} \tag{23}$$
Coboundaries being given by $S_L^{00}\Delta_{[0]}$[arbitrary $(U_{\alpha j}[\Phi], S_{\alpha}^{ij}[\Phi])$], the analysis of the cocycle condition $S_L^{00}\Delta_{[+1]} = 0$ leads to:

\begin{equation}
\Delta_{[+1]}^{an,(1)} = \int d^2 x d^2 \theta t_{ij}^{[ijkl]}(\Phi)[d^+_\alpha d^+(d^-)^2 + d^-_\alpha d^-(d^+_\alpha)^2] + \int d^2 x d^2 \tilde{t}_{ij}^{[ijkl]}(\Phi)[d^+_\alpha D_+ \Phi^i D_+ \Phi^j D_+ \Phi^k - d^-_\alpha D_- \Phi^i D_- \Phi^j D_+ \Phi^k]
\end{equation}

where the constraints on the skew-symmetric tensors $t_{ij}^{[ijkl]}(\Phi)$ and $\tilde{t}_{ij}^{[ijkl]}(\Phi)$ which occur in the anomalous part are easily solved in the same adapted coordinate system as above:

- the tensor $t_{ij}^{[ijkl]}(\Phi)$ is a pure contravariant analytic skew-symmetric tensor,
- the tensor $\tilde{t}_{ij}^{[ijkl]}(\Phi) \equiv \partial_t [\tilde{t}_{ij}^{[ijkl]}(\Phi, \tilde{\phi}) - \partial_t t_{ij}^{[ijkl]}(\phi, \phi)]$ (and the complex conjugate relation), the other components vanish.

### 3.3.3 $N_{DA} = 2$

Here, we separate in $\Delta_{[+1]}^2$ the terms symmetric in the exchange of the indices $\alpha$ and $\beta$ of the 2 ghosts $d^\pm_{\alpha}$ and $d^\pm_{\beta}$ from the skew-symmetric ones:

\begin{equation}
\Delta_{[+1]}^2 \big|_{(\alpha \beta)} = d^+_\alpha d^+_\beta \int d^2 x d^2 \theta \{(d^-)^2 \eta_i \eta_j t^{[ijkl]}_{\alpha \beta} + d^- [\eta_i \eta_j D_+ \Phi^k t^{[ijkl]}_{\alpha \beta}] + \eta_i D_+ \eta_j s^{(ij)}_{\alpha \beta}] + \eta_k [D_+ \Phi^i D_+ \Phi^j t^{[ijkl]}_{\alpha \beta}] + \eta_i (D_+ \Phi^j t^{[ijkl]}_{\alpha \beta}) + \text{parity exchanged} + \nonumber \\
+ d^-_\alpha d^-_\beta \int d^2 x d^2 \theta \{(d^+ d^- \eta_i \eta_j t^{[ijkl]}_{\alpha \beta}) + [\eta_i (d^+ D_+ \Phi^k - d^- D_- \Phi^k) t^{[ijkl]}_{\alpha \beta} + \eta_i (d^+ D_+ \eta_j - d^- D_- \eta_j) s^{(ij)}_{\alpha \beta}] + \eta_k [D_+ \Phi^i D_+ \Phi^j t^{[ijkl]}_{\alpha \beta}] + \eta_i (D_+ \Phi^j t^{[ijkl]}_{\alpha \beta}) + \text{parity exchanged}
\end{equation}

\begin{equation}
\Delta_{[+1]}^2 \big|_{(\alpha \beta)} = d^+_\alpha d^+_\beta \int d^2 x d^2 \theta \{(\eta_i \eta_j (d^+ D_+ \Phi^a + d^- D_- \Phi^a) t^{[ijkl]}_{\alpha \beta} + \eta_i (d^+ D_+ \eta_j + d^- D_- \eta_j) s^{(ij)}_{\alpha \beta}] + \eta_k [D_+ \Phi^i D_+ \Phi^j t^{[ijkl]}_{\alpha \beta}] + \eta_i (D_+ \Phi^j t^{[ijkl]}_{\alpha \beta}) + \text{parity exchanged}
\end{equation}

Then, coboundaries being given by $S_L^{00}\Delta_{[0]}^2$[arbitrary $S_{\alpha}^{ij}[\Phi]$], the analysis of the cocycle condition $S_L^{00}\Delta_{[+1]}^2 = 0$ leads to:

\begin{equation}
\Delta_{[+1]}^{an,(2)} = d^+_\alpha d^+_\beta \int d^2 x d^2 \theta \eta_i \{(d^-)^2 \eta_j t^{[ijkl]}_{\alpha \beta}(\Phi) + (D_+)^2 \Phi^i t^{[ijkl]}_{\alpha \beta}(\Phi)\} + \text{parity exchanged} + \nonumber \\
+ d^-_\alpha d^-_\beta \int d^2 x d^2 \theta \eta_i \eta_j t^{[ijkl]}_{\alpha \beta}(\Phi) + \nonumber \\
+ d^-_\alpha d^-_\beta \int d^2 x d^2 \theta \eta_i \left[D_+ \Phi^j D_- \Phi^k t^{[ijkl]}_{\alpha \beta}(\Phi) + D_+ D_- \Phi^j t^{[ijkl]}_{\alpha \beta}(\Phi)\right]
\end{equation}
where the constraints on the tensors $t[^{ijk}\phi]$, $t^i[^{(a\beta\gamma)\phi}]$, $t^i[^{(a\beta\gamma)\phi}]$, $t^i[^{(a\beta\gamma)\phi}]$ and $t^i[^{(a\beta\gamma)\phi}]$ which occur in the anomalous part are easily solved in the same adapted coordinate system as above:

- the tensors $t[^{(a\beta\gamma)\phi}]$ and $t[^{(a\beta\gamma)\phi}]$ are pure contravariant analytic skew-symmetric tensors,
- the tensor $t^i[^{(a\beta\gamma)\phi}]$ is a mixed analytic tensor, \( i.e. t^a[^{(a\beta\gamma)\phi}] = t^a[^{(a\beta\gamma)\phi}](\phi^\epsilon) \),
- the tensor $t^i[^{(a\beta\gamma)\phi}] \equiv \partial_\alpha \partial_\beta t^i[^{(a\beta\gamma)\phi}(\phi, \bar{\phi})]$ and the tensor $t^i[^{(a\beta\gamma)\phi}] \equiv \partial_b t^i[^{(a\beta\gamma)\phi}(\phi, \bar{\phi})]$ (and the complex conjugate relations), the other components vanish.

3.3.4 \( N_{d_3} = 3 \)

In that sector, there are no coboundaries, and the analysis of the cocycle condition $S_{L}^{00} \Delta_{[-1]}^3 = 0$ with:

$$
\Delta_{[-1]}^3 = d^\alpha d^\beta d^\gamma \int d^2x d^2\theta \{ d^\delta \eta_\gamma \eta_k t[^{(ijk)\phi}] + \eta \eta_{ij} t[^{(ij)\phi}] D^k + \eta D^i + \eta \eta_s[^{(ij)\phi}] \} + \text{parity exchanged}
$$

leads to:

$$
\Delta_{[-1]}^{an.3} = d^\alpha d^\beta d^\gamma d^\delta \int d^2x d^2\theta \eta_\gamma \eta_k t[^{(ijk)\phi}] (\Phi) + \text{parity exchanged}
$$

where the constraints on the skew-symmetric tensor $t[^{(ijk)\phi}]$ which occurs in the anomalous part are easily solved in the same adapted coordinate system as above and again means that it is a pure contravariant analytic skew-symmetric tensor.

3.3.5 \( N_{d_3} = 4 \)

In that sector too, there are no coboundaries, and the analysis of the cocycle condition $S_{L}^{00} \Delta_{[-1]}^4 = 0$ with:

$$
\Delta_{[-1]}^4 = d^\alpha d^\beta d^\gamma d^\delta \int d^2x d^2\theta \eta_\gamma \eta_k t[^{(ijk)\phi}] (\Phi)
$$

leads to:

$$
\Delta_{[-1]}^{an.4} = d^\alpha d^\beta d^\gamma d^\delta \int d^2x d^2\theta \eta_\gamma \eta_k t[^{(ijk)\phi}] (\Phi)
$$

where the constraints on the skew-symmetric tensor $t[^{(ijk)\phi}]$ which occurs in the anomalous part are easily solved in the same adapted coordinate system as above and again means that it is a pure contravariant analytic skew-symmetric tensor.

This ends the analysis of the cohomology of $S_{L}^{00}$ and we are now in a position to discuss the cohomology of the complete $S_{L}^{00} \equiv S_{L}^{00} + S_{L}$ operator.

4 The cohomology of $S_{L}^{00}$

It will be convenient to analyse the cohomology of $S_{L}^{00}$ in a coordinate system where the complex structure $J_3$ is constant. $S_{L}^{00}$ of eq. (10) is unchanged (with $J^i_3(0) \to J^i_3$, field independent) and we note that

$$
S_{L}^{i} = \int d^2x d^2\theta \frac{\delta A^{inv.}}{\delta \phi^i(x, \theta)} \frac{\delta}{\delta \eta_\phi(x, \theta)}
$$

(31)
decreases the number of $\eta_i$ of one unity, whereas $S_{L}^{00}$ does not change this number. Using this fact, we are able to construct the $S_{L}^{0}$ cohomology starting from the $S_{L}^{00}$ one: indeed,

$$S_{L}^{0} \Delta_{\phi \pi} \equiv (S_{L}^{00} + S_{L}^{r})(\Delta^{an}_{\phi \pi} + \tilde{\Delta}_{\phi \pi}) = 0 \iff S_{L}^{00} \tilde{\Delta}_{\phi \pi} = -S_{L}^{r}(\Delta^{an}_{\phi \pi} + \tilde{\Delta}_{\phi \pi}) \ .$$

Then, when ordered by decreasing order with respect to the total number of $\eta_i$, the equation $S_{L}^{0} \Delta_{\phi \pi} = 0$ is identical to the $S_{L}^{00} \Delta_{\phi \pi} = 0$ one with a right hand side given by previous order contributions.

### 4.1 The Faddeev-Popov negatively charged sectors

Thanks to the simplicity of $\Delta_{-1}$ (11), the cohomology of the complete $S_{L}^{0}$ operator in the Faddeev-Popov charge -1 sector is easily obtained: the vector $V^i[\Phi]$ should satisfy:

- $\int d^{2}x d^{2}\theta \frac{\delta A^{inv.}}{\delta \Phi^i(x, \theta)} V^i[\Phi(x, \theta)] = 0 \iff V^i[\Phi]$ is a Killing vector for the metric $g_{ij}[\Phi]$

- $J^i_j[\Phi] \nabla_k V^j = \nabla_j V^i J^k_i[\Phi] \iff V^i[\Phi]$ is a contravariant vector analytic with respect to $J^i_j[\Phi]$. Let us now turn to the Faddeev-Popov neutral charge sector.

### 4.2 The Faddeev-Popov 0 charge sector

As explained in the appendix of (I) (see also [16],[17]), despite the non-vanishing $S_{L}^{00}$ cohomology in a Faddeev-Popov positively charged sector (subsection 3.3), the cohomology of $S_{L}^{0}$ is a subspace of the one of $S_{L}^{00}$, i.e. one can always construct the cocycles for $S_{L}^{0}$ starting from those of $S_{L}^{00}$. It may also happen that some of the so doing constructed cocycles for $S_{L}^{0}$ become coboundaries: this occurs when there is some cohomology for $S_{L}^{00}$ in the Faddeev-Popov charge -1 sector ((I) and [25]). We have previously seen that this relies on the existence of Killing vectors for the metric $g_{ij}[\Phi]$; this is natural as such vectors signal extra isometries that constrain the invariant action or, equivalently, signal the non physically relevant character of some of the parameters of the classical action that may be reabsorbed through a conveniently chosen field and source reparametrisation [16].

As in the previous section, the analysis separates with respect to the number $N_{d_\alpha}$:

#### 4.2.1 $N_{d_\alpha} = 0$

The image of $\Delta_{[0]}^{0}$ (13) through $S_{L}^{r}$ does not intercept $\Delta_{[+1]}^{an.(0)}$, the cohomology of $S_{L}^{00}$ in the anomaly sector. As a consequence ([17] and the appendix of (I)), there will be no obstruction in the construction of the cocycles of $S_{L}^{0}$ starting from those of $S_{L}^{00}$ and there is an isomorphism between the two cohomology spaces. Consequently, the cohomology in the $N_{d_\alpha} = 0$ Faddeev-Popov neutral sector is characterized by a symmetric tensor $t_{ij}[\Phi]$ such that $g'_{ij} = g_{ij} + \bar{h} t_{ij}$ is a metric, hermitian with respect to the very complex structure $J^i_j$ we started from, and such that $J^i_j$ is covariantly constant with respect to the covariant derivative with connexion $\Gamma^k_{ij}[g'_{mn}]$. This is the necessary stability of the N=2 supersymmetric theory which ensures that, at a given perturbative order where the Slavnov identity holds (absence of anomaly up to this order), the U.V. divergences in the Green functions may be compensated for through the usual renormalisation algorithm and normalisation conditions [7].
4.2.2 \( N_{d_a} = 1 \)

Here the image of \( \Delta^1_{[0]} \) \(^{(13)}\) through \( S^r_L \) intercepts \( \Delta^{an,(1)}_{[+1]} \), the cohomology of \( S^{an}_{L,0} \) in the anomaly sector. As a consequence \(^{(17)}\) and the appendix of \((I)\), this will restrict the cohomology \((16,17)\) in the considered sector. In fact, \( S^r_L \Delta^1_{[0]} = 0 \) gives (no coboundaries exist in that sector):

\[
\Delta^1_{[0]} = \Delta^{an,(1)}_{[0]} [U^i_{\alpha j} (\Phi), \ S^{ij}_{\alpha} (\Phi)] \text{[equ.(13)]}
\]

with \( U^i_{\alpha j} (\Phi) = -2 [J_{jk} S^{ki}_{\alpha} (\Phi)] \Leftrightarrow S^{ij}_{\alpha} = -\frac{1}{2} J^{jk} U^j_{\alpha k} \) \(^{(33)}\)

where the supplementary constraint on \( S^{ij}_{\alpha} \) is such that \( J^i_{\alpha j} + h U^i_{\alpha j} \) - which anticommutes with \( J^i_{\alpha j} \) - is now also covariantly constant with respect to the covariant derivative with connexion \( \Gamma^i_{\alpha j} [g_{mn}] \).

4.2.3 \( N_{d_a} = 2 \)

Here too, the image of \( \Delta^2_{[0]} \) \(^{(13)}\) through \( S^r_L \) intercepts \( \Delta^{an,(2)}_{[+1]} \), the cohomology of \( S^{an}_{L,0} \) in the anomaly sector, which will restrict the cohomology \((18,19)\) in the considered sector. Thanks to the simplicity of \( \Delta^2_{[0]} \) \(^{(13)}\), the analysis of the cocycle condition \( S^{an}_{L} \Delta^2_{[0]} = 0 \) in the one \( \eta_l \) subsector readily shows that the cohomology space of the complete \( S^r_L \) operator is empty in this \( N_{d_a} = 2 \), Faddeev-Popov neutral sector.

Finally, let us consider the Faddeev-Popov charge \(+1\) sector.

4.3 The Faddeev-Popov \(+1\) charge sector

Here too, the analysis separates with respect to the number \( N_{d_a} \).

4.3.1 \( N_{d_a} = 0 \)

The \( S^{an}_{L,0} \) cohomology was obtained in equ.(21):

\[
\Delta^{an,(0)}_{[+1]} = \int d^2x d^2 \theta [t^{ijk}_{\Phi}] \{(d^+)^2 (d^-)^2 \eta_i \eta_j \eta_k \} - \frac{3}{2} d^+ d^- \eta_i \eta_j \eta_k J_{kn} (d^+ D_{+} \Phi^n - d^- D_{-} \Phi^n)
\]

and, using the algorithm described by equ.(32), we find the \( S^0_L \) cohomology in the same sector to be:

\[
\Delta^{an,(0)}_{[+1]} = \int d^2x d^2 \theta [t^{ijk}_{\Phi}] \{(d^+)^2 (d^-)^2 \eta_i \eta_j \eta_k \} - \frac{3}{2} d^+ d^- \eta_i \eta_j \eta_k J_{kn} (d^+ D_{+} \Phi^n - d^- D_{-} \Phi^n)
\]

\[
- 3d^+ d^- \eta_i J_{jn} J_{km} D_{+} \Phi^n D_{-} \Phi^m
\]

\[
+ \frac{3}{4} J_{lm} J_{jm} J_{kl} (d^+ D_{+} \Phi^n D_{+} \Phi^m D_{-} \Phi^l - d^- D_{-} \Phi^n D_{-} \Phi^m D_{+} \Phi^l)
\]

\[
+ \int d^2x d^2 \theta t^1_{[nm]} [\Phi] \left( d^+ D_{+} \Phi^n D_{+} \Phi^m D_{-} \Phi^l - d^- D_{-} \Phi^n D_{-} \Phi^m D_{+} \Phi^l \right)
\]

\(^{(34)}\)

where \( t^1_{[ij]} [\Phi] \) is related to the pure contravariant analytic tensor \( t^{ijk}_{\Phi} \) through (in complex coordinates):

\[
t^1_{[ab]c}, \ t^1_{[ab]c} \neq 0, \text{ the others vanish;}
\]

\[
t^1_{[ab]c} = \frac{1}{4} \partial c g_{aa} g_{bb} K_{cd} t^{[a|b|d]} \text{ where } K \text{ is the Kähler potential}.
\]
4.3.2 $N_{da} = 1$

The $S_L^{00}$ cohomology was obtained in equ.(24):

$$
\Delta_{[+1]}^{an.(1)} = \int d^2x d^2\theta t_{[ij]}^{[a]}(\Phi)[d_+^a d^+(d^-)^2 + d_-^a d^-(d^-)^2] \eta_\alpha \eta_j \eta_k +
$$

$$
+ \int d^2x d^2\theta \tilde{t}_{\alpha[ijk]}(\Phi)[d_+^a D_+ \Phi^i D_+ \Phi^j D_- \Phi^k - d_-^a D_- \Phi^i D_- \Phi^j D_+ \Phi^k]
$$

Notice first that $S_L^r$ does not act on the second piece of $\Delta_{[+1]}^{an.(1)}$, which then is a true $S_L^0$ anomaly. Due to its similarity with $\Delta_{[+1]}^{an.(0)}$, the first part of $\Delta_{[+1]}^{an.(1)}$ is easily promoted to a complete $S_L^0$ cohomology:

$$
\Delta_{[+1]}^{an.(1)} = \int d^2x d^2\theta t_{[ij]}^{[a]}(\Phi)\{d_+^a d^+(d^-)^2 \eta_\alpha \eta_j \eta_k - \frac{3}{2} d_+^a d^- \eta_i \eta_j \eta_k J_{kn}(d_+D_+ \Phi^n - d_-D_- \Phi^n) + 3d_i^a d_\eta J_{jn} J_{kn} D_+ \Phi^n D_- \Phi^m + \frac{3}{2} J_{in} J_{jm} J_{kn} d_+^a D_+ \Phi^n D_+ \Phi^m D_- \Phi^l + \text{parity exchange}\}
$$

$$
+ \int d^2x d^2\theta (2t_{[ij]}^1(\Phi) + \tilde{t}_{\alpha[ijk]}(\Phi))(d_+^a D_+ \Phi^i D_+ \Phi^j D_- \Phi^k - d_-^a D_- \Phi^i D_- \Phi^j D_+ \Phi^k)
$$

(35)

where $t_{[ij]}^1(\Phi)$ is related to the pure contravariant analytic tensor $t_{[ij]}^{[a]}(\Phi)$ as in the $N_{da} = 0$ case, and $\tilde{t}_{\alpha[ijk]}(\Phi)$ is related to a covariant vector $t_{\alpha[i]}$ (see subsection 3.3.2).

4.3.3 $N_{da} = 2$

The $S_L^{00}$ cohomology was obtained in equ.(26):

$$
\Delta_{[+1]}^{an.(2)} = \Delta_{[+1]}^{an.(2)} |_{(\alpha \beta)++} + \Delta_{[+1]}^{an.(2)} |_{(\alpha \beta)--} + \Delta_{[+1]}^{an.(2)} |_{(\alpha \beta)+-} + \Delta_{[+1]}^{an.(2)} |_{(\alpha \beta)--}
$$

where:

$$
\Delta_{[+1]}^{an.(2)} |_{(\alpha \beta)++} = d_+^a d_\beta^+ \int d^2x d^2\theta \eta_i [(d^-)^2 \eta_j \eta_k t_{\alpha \beta}^{[ij]}(\Phi) + (D_+)^2 \Phi^j t_{\alpha \beta}^{[i]}(\Phi)]
$$

$$
\Delta_{[+1]}^{an.(2)} |_{(\alpha \beta)+-} = d_+^a d_\delta^- d_\beta^+ d^- \int d^2x d^2\theta \eta_i \eta_j \eta_k t_{\alpha \beta}^{[ij]}(\Phi)
$$

$$
\Delta_{[+1]}^{an.(2)} |_{(\alpha \beta)--} = d_+^a d_\delta^- \int d^2x d^2\theta \eta_i \left[D_+ \Phi^j D_- \Phi^k t_{[\alpha \beta]}^{[ij]}(\Phi) + D_+ D_- \Phi^j t_{[\alpha \beta]}^{[i]}(\Phi)\right]
$$

- As $S_L^{00} \Delta_{[+1]}^{2}$ contains at least one source $\eta_i$, and $S_L^r$ decreases the number of $\eta_i$ of one unity, the $[\alpha, \beta]$ skew-symmetric part of the looked-for cocycles of $S_L^0$, $\Delta_{[+1]}^{2} |_{[\alpha \beta]}$ should satisfy

$$
(S_L^r \Delta_{[+1]}^{2}) |_{[\alpha \beta]} = 0
$$

which readily gives:

$$
(\Delta_{[+1]}^{2} |_{[\alpha \beta]})_{1\eta} = S_L^r \left(d_+^a d_\beta^- \int d^2x d^2\theta \eta_i \eta_j T_{[\alpha \beta]}^{[ij]}(\Phi)\right).
$$
The cocycle condition \((S^0_L + S'_L)\Delta^\text{an.(2)}_{[+1]} |_{[\alpha\beta]} = 0\) constrains \(T^{[ij]}_{[\alpha\beta]}\) to be a pure contravariant analytic skew-symmetric tensor; then, as a consequence of \((18),(19)\), the last parenthesis is annihilated by \(S^0_L\) and \(\Delta^2_{[+1]} |_{[\alpha\beta]}\) is in fact a \(S^0_L\) coboundary.

- In the same way, the cocycle condition \(S^0_L \Delta^2_{[+1]} |_{[\alpha\beta]+} = 0\) when analysed by increasing number of sources \(\eta\), leads to \(\Delta^\text{an.(2)}_{[+1]} |_{[\alpha\beta]+} = 0\).

- Finally, the cocycle condition \(S^0_L \Delta^2_{[+1]} |_{[\alpha\beta]+} = 0\) is analysed along the same lines as \(S^0_L \Delta^3_{[+1]} = 0\), and leads to:

\[
\Delta^\text{an.(2)}_{[+1]} = d^+_{\alpha} d^+_{\beta} \int d^2 x d^2 \theta t^{[ijk]}_{(\alpha\beta)} [\Psi] \left\{ (d^-)^2 \eta_i \eta_j \eta_k + \frac{3}{2} [\eta_i \eta_j J_{kn} d^- D_+ \Phi^n + \eta_i \eta_j J_{kn} D_+ \Phi^n D_+ \Phi^{n\eta}] \right\} \\
+ d^+_{\alpha} d^+_{\beta} \int d^2 x d^2 \theta \eta_i t^j_{(\alpha)(\beta)j} [\Psi] (D_+)^2 \Phi^j \\
+ \text{parity exchange}, \quad (36)
\]

where:

- as usual, \(t^{[ijk]}_{(\alpha\beta)} [\Psi]\) is a pure contravariant analytic skew-symmetric tensor, further constrained so as the corresponding \(t^i_{(\alpha\beta)j} [\Phi]\) tensor actually vanishes, i.e. in complex coordinates,

\[
t^{[abc]}_{(\alpha\beta)} = t^{[abc]}_{(\alpha\beta)} (\phi^d) ; \quad t_{(\alpha\beta) [abc]} = g_{\alpha\beta} g_{\alpha\gamma} t^{[abc]}_{(\alpha \beta) \gamma} (\phi^d) = t_{(\alpha\beta) [abc]} (\phi^d)
\]

and the complex conjugate relations;

- \(t^i_{(\alpha\beta)j} [\Phi]\) is a mixed analytic tensor, further constrained so as the tensor \(G_{(\alpha\beta) ij} = g_{jk} t^k_{(\alpha\beta)j}\) is a symmetric, covariantly constant tensor (hermitian with respect to the complex structure \(J^i_j\) due to previous relations (subsection 3.3.3)). This will be important in the following (subsection 5.1.6).

4.3.4 \(N_{d_0} = 3\)

There are no coboundaries in that sector, and the \(S^0_L\) cohomology was obtained in equ.(28). Notice that \(S^0_L \Delta^3_{[+1]}\) contains at least two sources \(\eta_i\) and that \(S^L_0\) decreases the number of \(\eta_i\) of one unity; then, when analysed by increasing number of sources \(\eta_i\), the cocycle condition \(S^0_L \Delta^3_{[+1]} = 0\), leads to \(\Delta^3_{[+1]} = 0\).

4.3.5 \(N_{d_0} = 4\)

There are no coboundaries in that sector, and the \(S^0_L\) cohomology was obtained in equ.(30). Notice that \(S^0_L \Delta^4_{[+1]}\) contains at least three sources \(\eta_i\) and \(S^L_0\) decreases the number of \(\eta_i\) of one unity; here again, when analysed by increasing number of sources \(\eta_i\), the cocycle condition \(S^0_L \Delta^4_{[+1]} = 0\), leads to \(\Delta^4_{[+1]} = 0\).

To sum up, the cohomology space of \(S^0_L\) in the Faddeev-Popov charge +1 sector depends on skew-symmetric contravariant analytic 3-tensors \(t^{[ijk]}_{[\alpha\beta]} [\Psi], t^{[ijk]}_{(\alpha\beta)j} [\Phi]\) and \(t^{[ijk]}_{(\alpha)} [\Psi]\), the last one endowing a further constraint, on a vector \(t_{\alpha i}\) and on a symmetric, covariantly constant tensor \(G_{(\alpha\beta) ij}\), hermitian with respect to the complex structure \(J^i_j\).

We are now in a position to compute the cohomology of the complete \(S_L = S^0_L + S^L_1 + S^2_L\) operator. But, as an intermediate result, we comment on \(N = 2\) supersymmetric non-linear \(\sigma\) models [21].
4.4 N=2 supersymmetric non-linear σ models

In the special case of N=2 supersymmetric non-linear σ models, there is no need for ghosts \( d^\pm_\alpha \) and all the necessary results may be found in subsections 4.1, 4.2.1 and 4.3.1. In particular, equation (34) offers a candidate for an anomaly and, as a consequence, if at a given perturbative order this anomaly appears with a non zero coefficient

\[
S^0_L[\Gamma]|_{\varphi^{\text{pert}}} = a(h)^{p} \Delta_{[+1]}^{an}, \quad a \neq 0
\]

the N = 2 supersymmetry is broken as \( \Delta_{[+1]}^{an} \) cannot be reabsorbed (being a cohomology element, it is not a \( S^0_L[\tilde{\Delta}_{[0]}] \) and, \( a \) \textit{a priori}, we are no longer able to analyse the structure of the U.V. divergences at the next perturbative order, which is the death of the theory.

We now discuss some properties of the candidate anomaly, trying to characterize the special geometries (and manifolds \( \mathcal{M} \)) where such pure contravariant analytic skew-symmetric 3-tensor cannot appear.

Consider the covariant tensor

\[
t_{[abc]} = g_{a\bar{a}}g_{b\bar{b}}g_{c\bar{c}}t^{[\bar{a}\bar{b}\bar{c}]}[\bar{\phi}].
\]

It satisfies \( \nabla_d t_{[abc]} = 0 \). The (3-0) form

\[
\omega' = \frac{1}{3!} t_{[abc]} d\phi^a \wedge d\phi^b \wedge d\phi^c
\]

which satisfies \( d'\omega' = 0 \) \(^{10}\), will now be shown to be harmonic if \( \mathcal{M} \) is a compact manifold (or if it is a \textit{Ricci-flat} one - for example an HyperKähler manifold).

One firstly obtains from the identity :

\[
\Delta t_{ijk} = g^{m n} \nabla_m \nabla_n t_{[ijk]} - [R^k_i t_{[ljk]} + \text{perm.}] - [R^l_{ij} t_{[lmk]} + \text{perm.}]
\]

rewritten in complex coordinates and due to \( \nabla_d t_{[abc]} = 0 \) :

\[
\Delta t_{[abc]} = g^{dd} \nabla_d \nabla_d t_{[abc]} - [R^d_a t_{[abc]} + \text{perm.}].
\]

On another hand, the Ricci identity gives, still using \( \nabla_d t_{[abc]} = 0 \) :

\[
g^{dd} \nabla_d \nabla_d t_{[abc]} = g^{dd}[R^c_{d\alpha} t_{[\alpha bc]} + \text{perm.}] = -[R^d_a t_{[abc]} + \text{perm.}].
\]

Then \( \Delta t_{[abc]} = 2 g^{dd} \nabla_d \nabla_d t_{[abc]} = 2 [R^d_a t_{[abc]} + \text{perm.}] \). In the Ricci-flat case, this gives the claimed harmonicity of \( \omega' \). Now, when the manifold is a compact one, one may compute :

\[
(d\omega', d\omega') + (\delta\omega', \delta\omega') = (\omega', (d\delta + \delta d)\omega') = (\omega', \Delta\omega') = \int_{\mathcal{M}} d\sigma 2 t_{[abc]} g^{dd} \nabla_d \nabla_d t_{[abc]} = 0 - 2(d\omega', d\omega') \Rightarrow (\delta\omega', \delta\omega') + 3(d\omega', d\omega') = 0 \Rightarrow \delta\omega' = d\omega' = \Delta\omega' = 0,
\]

\(^{10}\) As usual in complex geometry, see for example ([27], [28]), the differential \( d \equiv d' + d'' \), the codifferential \( \delta \equiv \delta' + \delta'' \) and the Laplacian \( \Delta \equiv \delta d + \delta d \).
and, as a consequence:

\[ [R^d_a t_{[abc]} + \text{perms.}] = 0 \Rightarrow 3t^{[abc]} R^a' t_{abc} = 0 . \]  

Moreover, in this compact case, it results from the previous discussion that \( [\partial dt_{[ab]} e]_{(a,b,d \ a.s.)} = \frac{1}{4} \partial d t_{[ab]} \) vanishes. As a consequence, \( t_{[ab]} e = \partial \bar{t}_{ab} - (a \leftrightarrow b) \), which corresponds to a trivial cohomology and is then thrown away from equation (34).

Notice that, as \( a \text{ priori } d \omega' \neq 0 \), this harmonicity is only a necessary condition which, to my knowledge, is not given in the mathematics literature. For example, in [27], page 70, only a more restrictive necessary and sufficient condition is given:

On a compact Kählerian manifold, given a \((p,0)\) form \( \eta \), the 3 following conditions are equivalent: \( \eta \) is closed, \( \eta \) is holomorphic and \( \eta \) is harmonic,

or in [28], theorem 9.3:

On a compact Kählerian manifold, given a pure skew-symmetric covariant tensor, a necessary and sufficient condition for it to be analytic is that it be harmonic.

Other necessary and sufficient conditions depend on the sign of the Ricci tensor: for example [27], theorem 9.6:

If the Ricci tensor is positive definite, there exists no contravariant analytic tensor. This results immediately from (39).

It is known that the number of such harmonic \((3,0)\) forms is given by the Hodge number \( h_{(3,0)} \); then this number determines an upper bound for the dimension of the cohomology space of \( S^0_L \) in the anomaly sector.

As a first result, this proves that if the manifold \( \mathcal{M} \) has a complex dimension smaller than 3, there is no anomaly candidate.

Another special case is the compact Kähler homogeneous one (N=2 supersymmetric extension of our previous works (I) for N=1 susy and [10] for the purely bosonic case): in such a case the Ricci tensor is positive definite [29] which, due to the aforementioned theorem, forbids the existence of such analytic tensor \( r^{[abc]}(\phi^d) \). As a consequence, the cohomology of \( S^0_{L0} \) - and then of \( S^0_L \) - vanishes in the anomaly sector, i.e. the Slavnov identity is not anomalous, which means that, as expected, N=2 supersymmetry is renormalisable (at least in the absence of torsion).

Moreover, due to the “stability” \footnote{The trivial cohomology \( S^0_L \Delta_{[-1]} \) corresponds to field and source reparametrisations according to [13].} of the complex structure and of the classical action in the space of Kähler metrics (subsection 4.2.1), in this case of \( d=2 \), N=2 non-linear \( \sigma \) models, the renormalisation algorithm \( a \text{ priori} \) does not change the number of parameters with respect to the one of the classical action. Of course, as mentioned in subsections 4.1 and 4.2, in the presence of Killing vectors, \( i.e. \) of extra isometries, the generic symmetric, Kählerian metric tensor \( t_{ij}[\Phi] \) gets some more constraints. For example, when the manifold is an homogeneous Kähler one (usual non linear \( \sigma \) models on coset spaces), up to infra-red analysis, our work extends to the N=2 supersymmetric case the renormalizability proof given for the bosonic case in [11] (and for the N=1 case in Section 5 of (I)).

Of course, when \( h_{(3,0)} \neq 0 \) - which for example occurs for Calabi-Yau manifolds, \( i.e. \) compact Ricci-flat Kähler manifolds of complex dimension 3, where \( h_{(3,0)} = 1 \text{ (ref. [3])} \footnote{As \( \det \|g\| = 1 \), a representative of \( t^{[abc]} \) is the constant skew-symmetric tensor \( \epsilon^{[abc]} \) \footnote{with \( \epsilon^{123} = +1 \).}\) - we have a true anomaly candidate [21]. Of course, as no explicit metric is at hand, one cannot compute the anomaly coefficient.
Some comments on its possible vanishing in perturbation theory will be offered in the Concluding Section.

This anomaly in global extended supersymmetry is a surprise with respect to common wisdom \[\text{[13]}\] (but see other unexpected non-trivial cohomologies in supersymmetric theories in the recent works of Brandt \[\text{[19]}\] and Dixon \[\text{[20]}\]) and the fact that if we have chosen, from the very beginning, a coordinate system adapted to the complex structure, the second supersymmetry will be linear and there will be no need for sources $\eta_i$. However, as known from chiral symmetry, even a linearly realised transformation can lead to anomalies; moreover, here the linear supersymmetry transformations do not correspond to an ordinary group but rather to a supergroup where, contrarily to ordinary compact groups, no general theorems exist; then there is no obvious contradiction. This emphasizes the special structure of the supersymmetry algebra.

5 The cohomology of $S_L$ and N=4 supersymmetry

In subsection 2.1, we have split the complete linearised B.R.S. operator $S_L$ into 3 pieces, according to their number of ghosts $d^\pm_\alpha$:

$$S_L = S^0_L + S^1_L + S^2_L$$

where:

$$S^0_L = \int d^2x d^2\theta \{ J^i_j (d^+_i D_+ \Phi^j + d^-_i D_- \Phi^j) \frac{\delta}{\delta \Phi^i} + \frac{\delta A^{inv.}}{\delta \Phi^i} + \eta_k (J^k_{j,i} - J^k_{i,j}) (d^+_i D_+ \Phi^j + d^-_i D_- \Phi^j) + J^j_i (d^+_i D_+ \eta_j + d^-_i D_- \eta_j) \frac{\delta}{\delta \eta_i} \}$$

$$S^1_L = \int d^2x d^2\theta \{ [J^j_{\alpha,i} (d^+_\alpha D_+ \Phi^j + d^-_\alpha D_- \Phi^j) + \eta_j \epsilon_{\alpha\beta\gamma} J^{ij}_{\beta} (d^+_\alpha d^- - d^-_\alpha d^+) \frac{\delta}{\delta \Phi^j}$$

$$+ [J^j_{\alpha,i} (d^+_\alpha D_+ \eta_j + d^-_\alpha D_- \eta_j) + \eta_k (J^k_{\alpha,j} - J^k_{\alpha,j}) (d^+_\alpha D_+ \Phi^j + d^-_\alpha D_- \Phi^j) +$$

$$+ \frac{1}{2} \eta_k \eta_l \epsilon_{\alpha\beta\gamma} J^{kl}_{\beta,i} (d^+_\alpha d^- - d^-_\alpha d^+) \frac{\delta}{\delta \eta_i}] \}$$

and

$$S^2_L = -\epsilon_{\alpha\beta\gamma} d^+_{\alpha} d^-_{\beta} \int d^2x d^2\theta \left[ \eta_j J^{ij}_{\delta} \frac{\delta}{\delta \Phi^i} + \frac{1}{2} \eta_k \eta_l J^{kl}_{i} \frac{\delta}{\delta \eta_i} \right]$$

(40)

and the cohomology of $S^0_L$ was obtained in the previous Section. We start the analysis by the anomaly sector, as the existence of a true Slavnov anomaly would be the death of the theory.

5.1 The Faddeev-Popov +1 charge sector

Filtering the cocycle condition $S_L \Delta_{[+1]} = 0$ with respect to the number $N_{d^\pm_\alpha}$, we know that the cohomology of $S_L$ will be a subspace of the one of $S^0_L$. We now analyse this restriction of the cohomology space (due to a possible Faddeev-Popov +2 charge anomaly) in successive filtration orders.

\[\text{[13]}\] In the appendix A of ref. \[\text{[16]}\], it is proven that any linearly realised symmetry corresponding to a compact group can be implemented to all orders of perturbation theory.
5.1.1 \( N_{da} = 0 \)

The cocycle condition \( S_L^0 \Delta^0_{[+1]} = 0 \) has been solved in subsection 4.3.1 (equ.(34)):

\[
\Delta^0_{[+1]} = \Delta^{an,(0)}_{[+1]} [t^{[ijk]}(\Phi)] + S_L^0 \Delta^0_{[0]} \]

5.1.2 \( N_{da} = 1 \)

At this order, and using previous result, the cocycle condition writes:

\[
S_L^0 (\Delta^1_{[+1]} - S_L^1 \Delta^0_{[0]}) = -S_L^1 \Delta^{an,(0)}_{[+1]} [t^{[ijk]}(\Phi)] \quad (41)
\]

From \( S_L^0 (S_L^1 \Delta^{an,(0)}_{[+1]}) = -S_L^1 (S_L^0 \Delta^{an,(0)}_{[+1]}) = 0 \), one sees that \( \text{a priori} \) enforces some constraints on the tensor \( t^{[ijk]}(\Phi) \). From the condition:

\[
S_L^1 \Delta^{an,(0)}_{[+1]} [t^{[ijk]}(\Phi)] = S_L^0 \tilde{\Delta}^1_{[+1]} \quad (42)
\]

where the general expression for \( \tilde{\Delta}^1_{[+1]} \) was given in (23), one obtains at decreasing orders in the number of ghosts, firstly a constraint on \( t^{[ijk]}(\Phi) \) : \( N_{d_A} = 6 \):

\[
\nabla_i [J^{ijklm}_\alpha] [j,k,l,m] \text{a.s.} = 0 ,
\]

then \( t^{[ijk]}(\Phi) \) in function of \( t^{[ijk]}(\Phi) \). Using complex coordinates - in particular the fact that \( J^{d\alpha}_d(\phi, \bar{\phi}) = \partial_d J^{d\alpha}_d(\phi, \bar{\phi}) \) - , this writes:

\[
\partial_d t^{[abc]}_\alpha = \frac{i}{4} J^{d\alpha}_d \nabla_d t^{[abc]}(\phi) = \partial_d \left[ \frac{i}{4} J^{d\alpha}_d(\phi, \bar{\phi}) \nabla_d t^{[abc]}(\phi) \right] ,
\]

\[
t^{[abc]}_\alpha = \frac{i}{4} J^{d\alpha}_d(\phi, \bar{\phi}) t^{[abc]}(\phi) ,
\]

which exhibits some arbitrariness in \( \tilde{\Delta}^1_{[+1]} \), defined up to a \( S_L^0 \) cocycle \( \Delta^{an,(1)}_{[+1]} [\text{equ.(34)}] + S_L^1 \Delta^0_{[0]} \). At the next order \( (N_{d_A} = 4) \) we obtain the vanishing of \( t^{[ijk]}(\Phi) \) i.e. of \( \Delta^{an,(0)}_{[+1]} \).

As a consequence, equ.(41) writes: \( S_L^0 (\Delta^1_{[+1]} - S_L^1 \Delta^0_{[0]}) = 0 \) which, according to subsection 4.3.2 (equ.(35)) solves to:

\[
\Delta^1_{[+1]} = \Delta^{an,(1)}_{[+1]} [t^{[ijk]}_\alpha(\Phi), \tilde{t}_\alpha^{[ijk]}(\Phi)] + S_L^0 \Delta^1_{[0]} + S_L^1 \Delta^0_{[0]} . \quad (43)
\]

5.1.3 \( N_{da} = 2 \)

At this order, and using previous results, the cocycle condition writes:

\[
S_L^0 (\Delta^2_{[+1]} - S_L^2 \Delta^0_{[0]} - S_L^1 \Delta^1_{[0]}) = -S_L^1 \Delta^{an,(1)}_{[+1]} [t^{[ijk]}_\alpha, \tilde{t}_\alpha^{[ijk]}] \quad (44)
\]

\footnote{In the compact Kähler case, we have shown in section 4.4 that \( \nabla t^{[ijk]} = 0 \) (as a consequence of \( d\omega' = 0 \)). Then this is not a new constraint.}
Here too, from $S_L^0(\Delta^\text{an.}_{[+1]} - \Delta^\text{an.}_{[0]} + S_L^0 \Delta^2_{[0]}) = 0$, one sees that (14) a \textit{priori} enforces some constraints on the tensors $t^i_{\alpha[jk]}$ and $\tilde{t}_{\alpha[ijk]}$. From the condition:

$$ S_L^1 \Delta^\text{an.}_{[+1]} [t^i_{\alpha[jk]}, \tilde{t}_{\alpha[ijk]}] = S_L^0 \tilde{\Delta}^2_{[+1]} $$

(45)

where the general expression for $\tilde{\Delta}^2_{[+1]}$ was given in (25) and is defined up to the cocycles $\Delta^\text{an.}_{[+1]}$ such that $\Delta^\text{an.}_{[+1]} + S_L^0 \Delta^2_{[0]}$, the same analysis as in the previous subsection for $N_{d_A} = 6, 5$ and 4 again gives the vanishing of $t^i_{\alpha[k]}(\Phi)$ and the “triviality” of the corresponding terms of $\tilde{\Delta}^2_{[+1]}$, as they reduce themselves to $S_L^0$ cocycles. Then $\Delta^\text{an.}_{[+1]}$ depends only on the tensor $t_{\alpha[ijk]}(\Phi)$. So $S_L^1 \Delta^\text{an.}_{[+1]}$ involves at most 3 ghosts and in $\tilde{\Delta}^2_{[+1]}$, only the terms in $t^i_{(\alpha\beta)} 4[jk]$, $t^i_{(\alpha\beta)} 4[jk]$, $t^i_{(\alpha\beta)} 4[jk]$ and $t^i_{(\alpha\beta) 5j}$, $t^i_{(\alpha\beta) 5j}$ survive.

When analysed at ghost level 3 and 2, the condition (45) does not lead to the vanishing of these tensors, but expresses them as functions of the complex structure $J^i_{\alpha j}$ and the “anomaly tensor” $\tilde{t}_{\alpha[ijk]}$. For example, one finds (in complex coordinates):

$$ t^a_{(\alpha\beta)} 4[bc] = t^a_{(\alpha\beta)} 4[bc] = 0, \ t^a_{(\alpha\beta)} 4[bc] = \frac{1}{4} \left( J^a_{\alpha \beta} \tilde{t}_{[\beta][d]} + (\alpha \leftrightarrow \beta) \right), $$

$$ t^a_{(\alpha\beta)} 5b = 0, \ t^a_{(\alpha\beta)} 5b, \tilde{\epsilon} = \frac{1}{2} \left( J^a_{\alpha \beta} \tilde{t}_{[\beta][d]} \tilde{\epsilon} + (\alpha \leftrightarrow \beta) \right), $$

and constraints such as:

$$ \left( J^a_{\alpha \beta} \tilde{t}_{[\alpha][\beta]} + J^a_{\alpha \beta} t_{[\beta][\beta]} + J^a_{\alpha \beta} \tilde{t}_{[\beta][\beta]} + (\alpha \leftrightarrow \beta) \right) = 0. $$

Finally, from (14), (15) and subsection 4.3.3, one gets:

$$ \Delta^2_{[+1]} = \Delta^\text{an.}_{[+1]} [t^i_{(\alpha\beta)}, t^i_{(\alpha\beta) 5j}] - \tilde{\Delta}^2_{[+1]} + S_L^0 \Delta^2_{[0]} + S_L^0 \Delta^2_{[0]} + S_L^0 \Delta^2_{[0]}, $$

(46)

where the tensor $G_{(\alpha\beta) i j} = g_{i k} t^k_{(\alpha\beta) 5j}$ is a symmetric, covariantly constant tensor, hermitian with respect to the complex structure $J^i_j$ (subsection 4.3.3).

5.1.4 $N_{d_A} = 3$

At this order, and using previous results, the cocycle condition writes:

$$ S_L^0 \left( \Delta^3_{[+1]} - S_L^0 \Delta^1_{[0]} - S_L^0 \Delta^2_{[0]} \right) = -S_L^2 \left( \Delta^\text{an.}_{[+1]} [\tilde{t}_{\alpha[ijk]}] \right) - $$$$ - S_L^1 \left( \tilde{\Delta}^2_{[+1]} [t^i_{(\alpha\beta)}, t^i_{(\alpha\beta) 5j}] + t^i_{(\alpha\beta) 4[jk]}, t^i_{(\alpha\beta) 4[jk]}, t^i_{(\alpha\beta) 4[jk]}, t^i_{(\alpha\beta) 5j}, t^i_{(\alpha\beta) 5j}] \right),$$

(47)

where $\tilde{\Delta}^2_{[+1]} = \Delta^\text{an.}_{[+1]} - \Delta^2_{[+1]}$. Here too, from $S_L^0(S_L^2 \Delta^\text{an.}_{[+1]} + S_L^1 \tilde{\Delta}^2_{[+1]} = -S_L^1 S_L^1 \Delta^\text{an.}_{[+1]} - S_L^1 S_L^1 \tilde{\Delta}^2_{[+1]} 0$, one sees that (17) a \textit{priori} enforces some new constraints on the tensor $t_{\alpha[ijk]}$. From the condition:

$$ S_L^2 \Delta^\text{an.}_{[+1]} + S_L^1 \tilde{\Delta}^2_{[+1]} = S_L^0 \tilde{\Delta}^3_{[+1]} $$

(48)
where the general expression for $\tilde{\Delta}^3_{[+1]}$ was given in (27), and thanks to the special structure of $S^L_2$ (10), one obtains through analysis of the terms in $d^+_\alpha d^+_\beta d^+\gamma$, at the 6 and 5 order in the total number of ghosts, the vanishing of the part in $t^{an,i}_{(\alpha\beta)}(\Phi)$ of the anomaly $\Delta_{[+1]}^{an,(2)}$ involved in $\tilde{\Delta}^3_{[+1]}$.

Then, the analysis of the terms in $d^-\alpha d^-\beta d^-\gamma$ gives:

- the symmetry, in the exchange $i \leftrightarrow j$, of : $\epsilon_{3\alpha\delta} J^{ki}_{\delta} \left[ t^{an,j}_{(\gamma\beta)} S_{5k} + t^{j}_{(\beta\gamma)5} S_{5k} \right]_{(\alpha\beta\gamma)}$ sym. ;
- the vanishing of $t^t_{(\beta\gamma)4\{ij\}}$, and then : $t^t_{\alpha\{ij\}k} = 0$ i.e. $\Delta_{[+1]}^{an,(1)} = 0$.

As a consequence, equ. (13) gives : $S^L_2\tilde{\Delta}^2_{[+1]} = 0$, and, thanks to previous remarks, $\tilde{\Delta}^2_{[+1]}$ may be suppressed, i.e. $t^t_{(\beta\gamma)5j} \equiv 0$. Then, the constraint (13) reduces itself to:

$$S^L_1\Delta_{[+1]}^{an,(2)} [t^{an,i}_{(\alpha\beta)5j}(\Phi)] = S^L_0\tilde{\Delta}^3_{[+1]}$$  \hfill (49)

In the analysis of the terms in $d^-\alpha d^-\beta d^-\gamma$, equ. (13) may be shown to enforce a stronger constraint on $t^{an,i}_{(\alpha\beta)5j}(\Phi)$:

$$J^i_{\alpha k} t^{an,k}_{(\beta\gamma)5} = J^k_{\alpha j} t^{an,i}_{(\beta\gamma)5} \iff J^i_{\alpha k} G_{(\beta\gamma)ij} = -G_{(\beta\gamma)ik} J^j_{\alpha i} \quad \forall \alpha, \beta, \gamma,$$  \hfill (50)
i.e. the tensor $G_{(\alpha\beta)ij}$ is hermitian with respect to the complex structures $J^i_{\alpha k}$. Moreover, $\tilde{\Delta}^3_{[+1]} \equiv 0$. Finally, from (17), (18) and subsection 4.3.4, one gets:

$$S^L_1\Delta_{[+1]}^{an,(2)} = 0 \quad ; \quad \Delta_{[+1]}^{3} = S^L_1\Delta_{[0]}^{2} + S^L_2\Delta_{[0]}^{1}.$$  \hfill (51)

5.1.5 $N_{da} = 4$

At this order, and using previous results, the cocycle condition writes:

$$S^L_0(\Delta_{[+1]}^{1} - S^L_2\Delta_{[0]}^{2}) = -S^L_2\Delta_{[+1]}^{an,(2)} [t^{an,i}_{(\alpha\beta)5j}]$$  \hfill (52)

Here too, from:

$$S^L_0(-S^L_2\Delta_{[+1]}^{an,(2)} = S^L_1(S^L_2\Delta_{[+1]}^{an,(2)}) B) 0,$$ one sees that (52) a priori enforces some constraint on the tensor $t^{an,i}_{(\alpha\beta)5j}$. From the condition:

$$S^L_2\Delta_{[+1]}^{an,(2)} = S^L_0\tilde{\Delta}_{[+1]}^{4}$$  \hfill (53)

where $\tilde{\Delta}_{[+1]}^{4}$ was given in (24), and the structures of $S^L_2$ (10) and $\Delta_{[+1]}^{an,(2)}$, one sees that the right hand side is proportional to $d^+_\alpha d^+_\beta d^+\gamma d^-\delta$ when no such terms may occur in the left hand side, which means that both sides should vanish. As a consequence, $\tilde{\Delta}_{[+1]}^{4}$ is a $S^L_0$ cocycle, which means that it vanishes (subsection 4.3.5).

Finally, from (52), (53) and subsection 4.3.5, one gets:

$$S^L_2\Delta_{[+1]}^{an,(2)} = 0 \quad ; \quad \Delta_{[+1]}^{4} = S^L_2\Delta_{[0]}^{2}.$$  \hfill (54)
5.1.6 Absence of N=4 supersymmetry anomaly

Putting the results of the previous subsections 5.1.1-5 altogether shows that the cohomology space of $S_L$ in the Faddeev-Popov charge +1 sector depends on a single symmetric tensor $G_{(\alpha\beta)ij}[\Phi]$, hermitian with respect to the 3 complex structures $J_{\alpha j}$ and covariantly constant:

$$
\Delta_{[+1]} = \Delta_{[+1]}^{an.(2)} + S_L \Delta_{[0]} \quad \text{where} \quad S_L^0 \Delta_{[+1]}^{an.(2)} = S_L^1 \Delta_{[+1]}^{an.(2)} = S_L^2 \Delta_{[+1]}^{an.(2)} = 0 ,
$$

$$
\Delta_{[+1]}^{an.(2)} = \int d^2 x d^2 \theta \eta_i g^{ij} G_{(\alpha\beta)k} (d_\alpha^+ d_\beta^+ (D_+)^2 \Phi^j + d_\alpha^- d_\beta^- (D_-)^2 \Phi^j) . \quad (55)
$$

This is reminiscent of the right hand side of the classical Slavnov identity \([3]\). As a matter of facts, it appears that $\Delta_{[+1]}^{an.(2)}$ is a $S_L$ cocycle:

$$
\Delta_{[+1]}^{an.(2)} = S_L \{ \Delta_{[0]} [G_{(\alpha\beta)ij}(\Phi)] \}
$$

$$
\Delta_{[0]} = \int d^2 x d^2 \theta \{ \eta_i g_{ij} D_+ \Phi D_+ \Phi^j - \frac{1}{2} \eta_i J^{ik}_{\alpha} G_{(\alpha\beta)kj} (d_\alpha^+ D_+ \Phi^j + d_\beta^- D_- \Phi^j) + \frac{1}{2} \eta_i J^{ik}_{\alpha} \epsilon_{ABC} d_A^+ d_B^+ [(a + \frac{1}{2}) J_{\alpha}^{ik} G_{(\gamma\gamma)kj} g^{lj} - \frac{1}{2} J_{\gamma}^{ik} G_{(\gamma\gamma)kj} g^{lj}] \} \quad (56)
$$

where $a$ is an arbitrary constant. Then there is no Faddeev-Popov $+1$ charge cohomology, and we get the absence of supersymmetry anomaly in N=4 non-linear $\sigma$ models in 2 space-time dimensions.

5.2 The Faddeev-Popov neutral charge sector

As explained before and in the appendix of (I), the existence of a non trivial cohomology for $S_L^0$ in the Faddeev-Popov $+1$ charge sector, will restrict the cocycles of $S_L$ in the Faddeev-Popov 0 charge sector; this is easily understood as N=4 supersymmetry enforces new constraints on the arbitrary Kählerian metric $g_{ij}$ corresponding to N=2 supersymmetry.

We now filter the cocycle condition $S_L^0 \Delta_{[0]} = 0$ with respect to the number $N_{d^\pm}$.

5.2.1 $N_{d^0} = 0$

The cocycle condition $S_L^0 \Delta_{[0]}^0 = 0$ has been solved in subsection 4.2.1:

$$
\Delta_{[0]}^0 = \Delta_{[0]}^{an.(0)} [t_{(ij)}(\Phi)] + S_L^0 \Delta_{[-1]}^0 [V^i(\Phi)]
$$

5.2.2 $N_{d^0} = 1$

At this order, and using previous result, the cocycle condition writes:

$$
S_L^0 (\Delta_{[0]}^0 - S_L^1 \Delta_{[-1]}^0 [V^i]) = -S_L^1 \Delta_{[0]}^{an.(0)} [t_{(ij)}(\Phi)] \quad (57)
$$

From $S_L^0 (S_L^1 \Delta_{[0]}^{an.(0)}) = -S_L^1 (S_L^0 \Delta_{[0]}^{an.(0)}) = 0$, and the existence of an $S_L^0$ anomaly $\Delta_{[+1]}^{an.(1)}$, one sees that (57) enforces some constraints on the tensor $t_{(ij)}(\Phi)$:

$$
S_L^1 \Delta_{[0]}^{an.(0)} [t_{(ij)}] = S_L^0 \tilde{\Delta}_{[0]}^1 [\tilde{U}_{ij}^\alpha, \tilde{S}_{ij}^\alpha] \quad (58)
$$
where the general expression for $\tilde{\Delta}^1_{[0]}$ was given in (13). As a consequence, equ.(57) writes:

$$S^0_L(\Delta^1_{[0]} - S^1_L\Delta^0_{[-1]} + \tilde{\Delta}^1_{[0]}) = 0$$

which, according to subsection 4.2.2 (see in particular equ.(33)), solves to:

$$\Delta^1_{[0]} = \Delta^a_{[0]}[U_{\alpha j}^{\cdot \cdot}, S^\alpha_{\alpha}] - \tilde{\Delta}^1_{[0]}[\tilde{U}_{\alpha j}^{\cdot \cdot}, \tilde{S}^\alpha_{\alpha}] + S^1_L\Delta^0_{[-1]}[V]^i$$

$$\equiv \tilde{\Delta}^1_{[0]}[U_{\alpha j}^{\cdot \cdot}, S^\alpha_{\alpha}] + S^1_L\Delta^0_{[-1]}[V]^i.$$  

$\tilde{\Delta}^1_{[0]}$ being defined by equation (58) up to a $S^0_L$ cocycle, i.e. up to $\Delta^a_{[0]}$, the constraint (58) especially implies the hermiticity of the perturbed metric $g'_{ij} = g_{ij} + \tilde{h}t_{ij}$ with respect to the perturbed complex structures $J'_{\alpha j} = J_{\alpha j} + \tilde{h}\tilde{U}_{\alpha j}$ and the covariant constancy of the later with respect to the covariant derivative with connexion corresponding to $g'_{ij}$. Moreover, the tensor $\tilde{S}^\alpha_{\alpha}$ is a pure contravariant analytic skew-symmetric tensor, with components given in complex coordinates by:

$$\tilde{S}^{[ab]}_{\alpha} = -\frac{i}{4}g^{\alpha \beta} \left[ \tilde{U}^{\beta}_{\alpha c} + t_{\cdot \cdot}^{\beta}_{\cdot \cdot}J^\alpha_{\alpha} \right] - (a \leftrightarrow b) \equiv \tilde{S}^{[ab]}_{\alpha} (\phi^d)$$

and the complex conjugate relation, (compare to equ.(33)), and one obtains the relations:

$$T_{\alpha [ab]} = -\frac{i}{4} \left[ g_{\alpha \beta} \tilde{U}^{\beta}_{\alpha b} + t_{\cdot \cdot}^{\beta}_{\cdot \cdot}J^\alpha_{\alpha} \right] - (a \leftrightarrow b) \equiv T_{\alpha [ab]} (\phi^d)$$

and

$$\tilde{U}^{\beta}_{\alpha \bar{a}} \left( \text{resp. } \tilde{S}^{[ab]}_{\alpha} \right) = -i\epsilon_{\alpha \beta \beta} \tilde{U}^{\beta}_{\alpha \bar{a}} \left( \text{resp. } \tilde{S}^{[ab]}_{\alpha} \right)$$

(compare to equ.(3) which implies : $J^b_{\alpha \bar{a}} = -i\epsilon_{\alpha \beta \beta} J^b_{\beta \bar{a}}$) and the complex conjugate relations.

### 5.2.3 $N_{da} = 2$

At this order, and using previous results, the cocycle condition writes:

$$S^0_L(\Delta^2_{[0]} - S^2_L\Delta^0_{[-1]} + \tilde{\Delta}^2_{[0]}) = -S^2_L\Delta^a_{[0]} - S^1_L\tilde{\Delta}^1_{[0]}$$

(60)

Here too, from

$$S^0_L \left( S^2_L\Delta^a_{[0]} + S^1_L\tilde{\Delta}^1_{[0]} \right) = -S^1_L(S^1_L\Delta^a_{[0]} - S^0_L\tilde{\Delta}^1_{[0]}) \equiv 0,$$  

and the existence of an $S^0_L$ anomaly $\Delta^a_{[+1]}$, one sees that (60) enforces some constraints on the tensors $t_{(ij)}$, $\tilde{U}_{\alpha j}$, $S^\alpha_{\alpha}$:

$$S^2_L\Delta^a_{[0]}[t_{(ij)}] + S^1_L\tilde{\Delta}^1_{[0]}[\tilde{U}_{\alpha j}, S^\alpha_{\alpha}] = S^0_L\tilde{\Delta}^2_{[0]}[\tilde{S}^{[ij]}_{\alpha \beta}]$$

(61)

where the general expression for $\tilde{\Delta}^2_{[0]}$ was given in (13). As a consequence of (61), equ.(60) writes:

$$S^0_L(\Delta^2_{[0]} - S^2_L\Delta^0_{[-1]} + \tilde{\Delta}^2_{[0]}) = 0$$

which, according to subsection 4.2.3 solves to:

$$\Delta^2_{[0]} = -\Delta^2_{[0]}[\tilde{S}^{[ij]}_{\alpha \beta}] + S^2_L\Delta^0_{[-1]}[V]^i.$$  

(62)
The constraint \((61)\) especially implies the anticommutation of the perturbed complex structures \(J^i_{\alpha j}\) and \(J^i_{\beta j}\) and the relation:
\[
\tilde{S}_{[\alpha \beta]}^{[ij]} = -\frac{1}{2} \epsilon_{\alpha \beta 33} J^i_{3m} t_{(m)n} g^{nj}.
\]

### 5.2.4 \(N_{da} = 3\)

At this order, and using previous results, the cocycle condition writes:
\[
S_L^2 \Delta_{[0]}^1 + S_L^1 \Delta_{[0]}^2 = 0
\]
\[
\Leftrightarrow S_L^1 \Delta_{[0]}^2 [\tilde{S}_{[\alpha \beta]}^{[ij]}] = S_L^2 \Delta_{[0]}^1 [U_{\alpha j}, S_{\beta}^{[ij]}].
\]

(63)

As a matter of facts, this may be shown to result from previous constraints.

### 5.2.5 \(N_{da} = 4\)

At this order, and using previous results, the cocycle condition writes:
\[
S_L^2 \Delta_{[0]}^2 = 0 \Leftrightarrow S_L^2 \Delta_{[0]}^2 [\tilde{S}_{[\alpha \beta]}^{[ij]}] = 0,
\]

(64)

which may be shown to result from the Ricci-flatness of \(g'_{ij}\) (\(\det \|g'\| = \text{constant}\)), which itself results from the HyperKähler nature of the perturbed metric \(g'_{ij}\), i.e. to results of the previous subsections.

### 5.2.6 Stability of N=4 supersymmetric non-linear \(\sigma\) models

Putting the results of the previous subsections 5.2.1-5 altogether gives:
\[
\Delta_{[0]} = \Delta_{[0]}^{an.(0)} [t_{(ij)}(\Phi)] + \Delta_{[0]}^1 [U_{\alpha j}(\Phi), S_{\alpha}^{[ij]}(\Phi)] - \Delta_{[0]}^2 [\tilde{S}_{[\alpha \beta]}^{[ij]}(\Phi)] + S_L \Delta_{[-1]} [V^i(\Phi)]
\]

(65)

Up to a trivial field and source reparametrisations \((7,8)\), the most general Slavnov invariant integrated functional of the fields, sources and their derivatives, of Faddeev-Popov 0 charge is:
\[
\Gamma'_{\text{class.}} = \Gamma_{\text{class.}} + h \Delta_{[0]}
\]
\[
\equiv \int d^2 x d^2 \theta \{ g_{ij} D_+ \Phi^i D^- \Phi^j + \eta_i J^{ij}_{\alpha j} [d_A^+ D_+ \Phi^j + d_A^- D_- \Phi^j] - \frac{1}{2} \epsilon_{ABC} \eta_i \eta_j J^{ij}_{\alpha} d_A^+ d_B^+ \}
\]

(66)

and where the results of the previous subsections consistently give:
\[
g'_{ij}[\Phi] = g_{ij}[\Phi] + h t_{(ij)} , \quad J'_{3j} = J'_{3j} , \quad J^{ij}_{\alpha j}(\Phi) = J^{ij}_{\alpha j}(\Phi) + h \tilde{U}_{\alpha j}(\Phi),
\]
\[
J^{ij}_{3k}(\Phi) = J^{ij}_{3k} + h \eta_i g^{nm} t_{(mr)} g^{kj} \text{subsect.} = 5.2.3 J^{ij}_{3j}(\Phi) + 2 h \epsilon_{\alpha \beta 3} \tilde{S}_{[\alpha \beta]}^{[ij]}(\Phi),
\]
\[
J^{ij}_{\alpha j}(\Phi) = J^{ij}_{\alpha j} + h \tilde{U}_{\alpha k} g^{kj} - J^{im}_{\alpha j} t_{(mn)} g^{nj} \text{subsect.} = 5.2.2 J^{ij}_{\alpha}(\Phi) - 2 h \epsilon_{\alpha \beta 3} \tilde{S}_{\beta}^{[ij]}(\Phi),
\]

(67)

and the different constraints \((58\text{ and }61)\) may be shown to enforce N = 4 supersymmetry : i.e. \(g'_{ij}[\Phi]\) is a symmetric metric tensor, the three \(J'_{A}'\)’s offer a set of anticommuting, integrable and
covariantly constant (with respect to the covariant derivative with connexion $\Gamma^i_{jk}$ corresponding to the metric $g'_{ij}$) complex structures satisfying a quaternionic multiplication law, and the metric is hermitian with respect to each of these complex structure $J^i_{A j}(\Phi)$.

This proves the stability of the theory, and, thanks to the absence of anomaly, the full renormalisability of $N = 4$ supersymmetric non-linear $\sigma$ models in two space-time dimensions.

Of course, due to a possible Faddeev-Popov charge non-trivial cohomology for $S_L$, some of the parameters of the action (66) may be unphysical ones. $\Delta_{[-1]}(V^i[\Phi])$ being independent of $d^a_i$, the cocycle condition $S_L \Delta_{[-1]}(V^i[\Phi]) = 0$ splits into the three ones $S_L^i \Delta_{[-1]}(V^i[\Phi]) = 0, \ i = 0, 1, 2$. One easily checks that $V^i[\Phi]$ should be a contravariant Killing vector for the metric $g_{ij}$, holomorphic with respect to the three complex structures:

$$g_{kj} \nabla_i V^k + g_{ki} \nabla_j V^k = 0; \quad J^j_{A i} \nabla_i V^k = J^i_{A k} \nabla_j V^j, \ A = 1, 2, 3.$$  \hfill (68)

### 6 Concluding remarks

In the second paper of this series, we have analysed the cohomology of the B.R.S. operator associated to $N = 2$ and $N = 4$ supersymmetry in a $N = 1$ superfield formalism. We found an anomaly candidate for torsionless models built on compact Kähler Ricci-flat target spaces with a non vanishing Hodge number $h^{(3,0)}$. Calabi-Yau manifolds (3 complex dimensional case) where $h^{(3,0)} = 1$ (ref. [3]) are interesting examples due to their possible relevance for superstring theories. Of course, as no explicit metric is at hand, one cannot compute the anomaly coefficient.

This anomaly in global supersymmetry is a surprise with respect to common wisdom [18]. But some recent works of Brandt [19] and Dixon [20] also show the existence of new non-trivial cohomologies in supersymmetric theories and we have argued in Section 4 that the special structure of the supersymmetry algebra which does not correspond to an ordinary group but rather to a supergroup may be responsible of this peculiarity.

Our analysis then casts some doubts on the validity of the previous claims on U.V. properties of $N=2$ supersymmetric non linear $\sigma$ models (see for example [4] or [6]): there, the possible occurrence, at 4-loops order, of (infinite) counterterms non-vanishing on-shell, even for Kähler Ricci-flat manifolds, did not "disturb" the complex structure. On the other hand, we have found a possible "instability" of the second supersymmetry, which confirms that there are some difficulties in the regularisation of supersymmetry by dimensional reduction assumed as well in explicit perturbative calculations [3] than in finiteness "proofs" [4] or higher order counterterms analysis [5]. We would like to emphasize the difference between Faddeev-Popov 0 charge cohomology which describes the stability of the classical action against radiative corrections (the usual "infinite" counterterms) and which offers no surprise, and the anomaly sector which describes the "stability" of the symmetry (the finite renormalisations which are needed, in presence of a regularisation that does not respect the symmetries of the theory, to restore the Ward identities): of course, when at a given perturbative order the Slavnov (or Ward) identities are spoiled, at the next order, the analysis of the structure of the divergences is no longer under control. In particular, the Calabi-Yau uniqueness theorem for the metric [30] supposes that one stays in the same cohomology class for the Kähler form, a fact which is not certain in the absence of a regularisation that respects the $N=2$ supersymmetry (the

---

\[15\] The trivial cohomology $S_L \Delta_{[-1]}$ corresponds to field and source reparametrisations according to (7,8).
possible anomaly we found expresses the impossibility to find a regularisation that respects all
the symmetries of these theories).

We emphasize that the present work relies heavily on a perturbative analysis of the possible
breakings of the Slavnov identity, especially through the use of the Quantum Action Princi-
ple. It may well happen that the coefficient of the anomaly candidate vanishes at any finite
perturbative order $^{16}$ However, the possibility of a non-perturbative breaking of the N=2
supersymmetry would remain open.

Of course, if one has added from the very beginning extra geometrical (or physical !) con-
straints that would fix the classical action, we bet that our anomaly candidate would disapear :
as previously mentionned, this is the case when the manifold is a compact homogeneous Kähler
space.

Moreover we have been able to give the first algebraic, regularisation free proof that, if one
enforces N=4 supersymmetry (HyperKähler manifolds) there is no supersymmetry anomaly $^{17}$
and that the corresponding non-linear $\sigma$ models are all-orders renormalisable, “à la Friedan”.

The last step of our program will be the rigorous proof of the all-orders finiteness of these
models. We hope to be able to report on that subject in a near future.
