Abstract

An explicit reciprocal transformation between a 2-component generalization of the Camassa-Holm equation, called the 2-CH system, and the first negative flow of the AKNS hierarchy is established, this transformation enables one to obtain solutions of the 2-CH system from those of the first negative flow of the AKNS hierarchy. Interesting examples of peakon and multi-kink solutions of the 2-CH system are presented.

Key words: Camassa-Holm equation, AKNS hierarchy, reciprocal transformation

1 Introduction

The Camassa-Holm equation, which was derived physically as a shallow water wave equation by Camassa and Holm in [7, 8], takes the form

$$u_t + \kappa u_x - u_{xxt} + 3u u_x = 2u_x u_{xx} + uu_{xxx} \quad (1.1)$$

where $u = u(x,t)$ is the fluid velocity in the $x$ direction and the constant $\kappa$ is related to the critical shallow water wave speed. The subscripts $x, t$ of $u$ denote the partial derivatives of the function $u$ w.r.t. $x, t$, for example, $u_t = \partial_t u$, $u_{xxt} = \partial_t \partial_x \partial_x u$, similar notations will be used frequently later in this paper. This equation first appeared in the work of Fuchssteiner and Fokas [16] on their theory of hereditary symmetries of soliton equations. As it was shown by Camassa and Holm, equation (1.1) shares most of the important properties of an integrable system of KdV type, for example, the existence of Lax pair formalism, the bihamiltonian structure, the multi-soliton solutions and the applicability of the inverse scattering method to its initial value problem. When $\kappa = 0$, the Camassa-Holm equation (1.1) has a peculiar property that its soliton solutions become piecewise smooth and have corners at their crests, such solutions are weak solutions of (1.1) and are called “peakons”. Since the works of Camassa and Holm, this equation has become a well known example of integrable systems and has been studied from various point views in, for example, [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26] and references therein.

We consider in this paper the following 2-component generalization of the Camassa-Holm equation

$$m_t + um_x + 2mu_x - \rho \rho_x = 0, \quad (1.2)$$

$$\rho_t + (\rho u)_x = 0. \quad (1.3)$$

Here $m = u - u_{xx} + \frac{1}{2} \kappa$. Under the constraint $\rho = 0$ this system is reduced to the Camassa-Holm equation (1.1). Such a generalization is based on the following consideration. We note the fact that
both bihamiltonian structures of the Camassa-Holm hierarchy and that of the KdV hierarchy are deformations of the following bihamiltonian structure of hydrodynamic type

\[ \{u(x), u(y)\}_1 = \delta'(x - y), \]
\[ \{u(x), u(y)\}_2 = u(x)\delta'(x - y) + \frac{1}{2} u(x)'\delta(x - y). \]  

(1.4)

This fact also implies that the dispersionless limit of the Camassa-Holm hierarchy coincides with that of the KdV hierarchy. It was shown in 23 that deformations of the bihamiltonian structure 1.3 that depend polynomially on the variables \( u_x, u_{xx}, \ldots \) are uniquely characterized, up to Miura type transformations, by a function \( c(u) \), this function is called the central invariant of the deformed bihamiltonian structure. For the KdV hierarchy the central invariant is a nonzero constant while for the Camassa-Holm hierarchy the central invariant is given by a nonzero constant multiplied by \( u \), so their bihamiltonian structures are representatives of two different classes of deformations of 1.4.

One of the main features of the integrable hierarchies that correspond to bihamiltonian structures with constant central invariants is the existence of tau functions 11, this property no longer holds true for integrable hierarchies that correspond to bihamiltonian structures with nonconstant central invariants. In fact, many of the well known integrable hierarchies of evolutionary PDEs with one spatial variable possess bihamiltonian structures that are deformations of bihamiltonian structure of hydrodynamic type with constant central invariants, and the existence of tau functions plays an important role in the study of these integrable systems. The Camassa-Holm hierarchy is an exceptional example of integrable systems which does not possess tau functions. Now let us consider the following bihamiltonian structure of hydrodynamic type

\[ \{w_1(x), w_1(y)\}_1 = \{w_2(x), w_2(y)\}_1 = 0, \]
\[ \{w_1(x), w_2(y)\}_1 = \delta'(x - y), \]
\[ \{w_1(x), w_1(y)\}_2 = 2\delta'(x - y), \]
\[ \{w_1(x), w_2(y)\}_2 = w_1(x)\delta'(x - y) + w_1'(x)\delta(x - y), \]
\[ \{w_2(x), w_2(y)\}_2 = [w_2(x)\partial_x + \partial_x w_2(x)]\delta(x - y). \]  

(1.5)

It was shown in 23 that the deformation with constant central invariants \( c_1 = c_2 = \frac{1}{\sqrt{24}} \) leads to the nonlinear Schrödinger hierarchy which can be converted to the AKNS hierarchy 2 after an appropriate transformation, and the one with central invariants \( c_1 = \frac{1}{\sqrt{24}} (w_1 + 2\sqrt{w_2})^2, c_2 = \frac{1}{\sqrt{24}} (w_1 - 2\sqrt{w_2})^2 \) leads to a bihamiltonian integrable hierarchy with 12, 16 as the first nontrivial flow under the change of coordinates

\[ w_1 = 2(u - u_x), \quad w_2 = -\rho^2 + (u - u_x)^2, \]  

(1.7)

the rescaling \( t \mapsto -t \) and the Galilean transformation \( x \mapsto x - \frac{1}{\sqrt{8}} \kappa t, t \mapsto t, \ u \mapsto u - \frac{1}{\sqrt{8}} \kappa, \ \rho \mapsto \rho \). So from the point of view of deformations of bihamiltonian structures of hydrodynamic type the systems 12, 16 have the same property, i.e., both of their bihamiltonian structures have nonconstant central invariants. Note that the bihamiltonian structure of the system 12, 16, as it was shown in 23, is obtained from 1.5, 1.6 by the addition of the deformation term \( -\delta''(x - y) \) to the bracket \( \{w_1(x), w_2(y)\}_1 \). We will call the system 12, 16 the 2-component Camassa-Holm (2-CH) system henceforth. This system was also derived independently by Falqui 14 by using the bihamiltonian approach.

The main result of the present paper is the establishment of a reciprocal transformation between the 2-CH system and the first negative flow of the AKNS hierarchy. Recall that the Camassa-Holm equation 11 has a similar relation with the first negative flow of the KdV hierarchy, the corresponding reciprocal transformation (also called a hodograph transformation) was found by Fuchssteiner in 12. Several attempts have been made to obtain solutions of the Camassa-Holm equation 11 from that of the first negative flow of the KdV hierarchy by using this reciprocal transformation in, for example, 9, 13, 20, 21, 22, 28. However, since the inverse of this reciprocal transformation involves the solving of a nonlinear ODE of second order, only particular solutions like the multi-soliton solutions were
obtained in explicit forms by using this approach. The advantage of the reciprocal transformation between the 2-CH system and the first negative flow of the AKNS hierarchy is that it gives an explicit correspondence between solutions of these two systems, this correspondence is presented in Theorems 2.1, 2.3 and Theorems 3.1, 3.2. In Sec. 2 and Sec. 3 we first give the construction of the reciprocal transformation, then in Sec. 4 we show some interesting examples of solutions of the 2-CH system that are obtained from solutions of the first negative flow of the AKNS hierarchy by using the reciprocal transformation, they include peakon and multi-kink solutions.

2 A reciprocal transformation for the 2-CH system

The 2-CH system is equivalent to the compatibility conditions of the following linear systems:

\[ \phi_{xx} + \left( -\frac{1}{4} + m \lambda - \rho^2 \lambda^2 \right) \phi = 0, \]  
\[ \phi_t + \frac{1}{2\lambda} \phi_x + \frac{u_x}{2} \phi. \]  

Here \( m = u - u_{xx} + \frac{1}{2} \kappa \). Since the term \( \frac{1}{2} \kappa \) can be canceled by a Galileo transformation, we assume \( \kappa = 0 \) in this and the next section. The linear equation (2.1) is known as the Schrödinger spectral problem with energy dependent potential. Antonowicz and Fordy considered the more general spectral problem

\[ \phi_{xx} + (c + u_1 \lambda + \cdots + u_n \lambda^n) \phi = 0 \]  

and associated to it \( n + 1 \) compatible local Hamiltonian structures in [4]. Here \( c \) is a given constant. In [4] it was also shown that (2.3) can be transformed to the spectral problem

\[ \psi_{xx} + (v_0 + v_1 \lambda + \cdots + v_{n-1} \lambda^{n-1}) \psi = \lambda^n \psi. \]  

We will use similar transformations below in order to relate the 2-CH system with the first negative flow of the AKNS hierarchy. The relations of the spectral problem (2.4) and its generalizations to multi-Hamiltonian structures and integrable systems were studied in [24, 5, 6], and in the particular case of \( n = 2 \) in [19]. The bihamiltonian structure of the 2-CH system [12], [13] was also given in [4] from the spectral problem (2.3) with \( n = 2 \). In [12] the bihamiltonian structures related to the generalized spectral problems of [6] were considered from the point of view of deformations of bihamiltonian structures of hydrodynamic type, their central invariants are in general non-constants.

Since when \( \rho \) vanishes, the 2-CH system (1.2), (1.3) degenerates to the Camassa-Holm equation (1.1), we assume hereafter \( \rho \neq 0 \). Equation (1.3) shows that the 1-form

\[ \omega = \rho \, dx - \rho \, u \, dt \]  

is closed, so it define a reciprocal transformation \( (x, t) \mapsto (y, s) \) by the relation

\[ dy = \rho \, dx - \rho \, u \, dt, \quad ds = dt, \]  

and we have

\[ \frac{\partial}{\partial x} = \rho \frac{\partial}{\partial y}, \quad \frac{\partial}{\partial t} = \frac{\partial}{\partial s} - \rho \, u \frac{\partial}{\partial y}. \]  

Denote \( \phi = \sqrt{\rho} \phi \), then the spectral problem (2.1), (2.2) is converted to the following one

\[ \varphi_{yy} + \left( -\lambda^2 + P \lambda + Q \right) \varphi = 0, \]  
\[ \varphi_s + \frac{\rho}{2 \lambda} \varphi_y - \frac{\rho u}{4 \lambda} \varphi = 0, \]  

where

\[ P = \frac{m}{\rho^2}, \quad Q = -\frac{1}{4 \rho^2} - \frac{\rho_{yy}}{2 \rho} + \frac{\rho_y^2}{4 \rho^2}. \]
Now let’s consider the isospectral problem (2.8), (2.9). The compatibility conditions read

\[ P_s = \rho_y, \]  
\[ Q_s + \frac{1}{2} \rho P_y + P \rho_y = 0, \]  
\[ \frac{1}{2} \rho Q_y + Q \rho_y + \frac{1}{4} \rho_{yy} = 0. \]

By integrating the third equation (2.13) and comparing the resulting equation with (2.10) we obtain

\[ \rho^2 Q + \frac{1}{2} \rho \rho_{yy} - \frac{1}{4} \rho^2_y = C = -\frac{1}{4}. \]  

From the equation (2.11) we know that there exists a function \( f(y,s) \) such that

\[ P = \frac{\partial f(y,s)}{\partial y}, \quad \rho = \frac{\partial f(y,s)}{\partial s}. \]

Substituting the expressions of \( P, Q, \rho \) that are given by (2.15) and the second formula of (2.10) into the equation (2.12) we arrive at the following equation for \( f \):

\[ \frac{f_{ss}}{2f_s^3} + \frac{f_y f_{ys}}{f_s} - \frac{f_{ss} f_{ys}}{2f_s^3} + \frac{f_{ys} f_{yss}}{2f_s^2} + \frac{1}{2} f_s f_{yy} + \frac{f_{ss} f_{yys}}{2f_s^2} - \frac{f_{yyss}}{2f_s} = 0 \]  

**Theorem 2.1** Let \( f \) be a solution of the equation (2.16), and

\[ u = f_y f_s^2 + \frac{f_{ss} f_{ys}}{f_s} - f_{yss}, \quad \rho = f_s. \]

If \( x(y,s) \) is a solution of the following system of ODEs:

\[ \frac{\partial x}{\partial y} = \frac{1}{\rho}, \quad \frac{\partial x}{\partial s} = u, \]

then \( (u(y,t), \rho(y,t), x(y,t)) \) is a parametric solution of the 2-CH system (1.2), (1.3).

**Remark** We say that the triple \( (u(y,t), \rho(y,t), x(y,t)) \) is a parametric solution of the 2-CH system if the functions \( u(x,t) = u(y(x,t), t), \rho(x,t) = \rho(y(x,t), t) \) satisfy the system (1.2), (1.3), where \( y = y(x,t) \) is the inverse function of \( x = x(y,t) \). For simplicity, we will use the same symbol \( u, \rho \) to denote the functions \( u(y(x,t), t), \rho(y(x(t), t) \) as functions of \( x \) and \( t \).

**Proof** Due to the definition of the reciprocal transformation, we only need to verify the validity of the equation

\[ u - u_{xx} = m = \rho^2 P = f_s^2 f_y. \]

Denote by \( E \) the l.h.s of equation (2.19). By using the definition (2.17) of the function \( u \) we obtain through a straightforward computation

\[ u - \rho (\rho u_y)_y - f_s^2 f_y + 2f_s^3 E_y + 4f_s^2 f_{ys} E = 0 \]

which yields (2.19). The theorem is proved. \( \square \)

**Definition 2.2** A function \( f = f(y,s) \) is called a primary solution of the 2-CH system (1.2), (1.3) if it satisfies the equation (2.16).
Given a solution \((u(x,t), \rho(x,t))\) of the 2-CH system (1.2), (1.3), the formulae (2.10) and (2.15) determines a primary solution \(f(y,s)\), we call it the primary solution that is associated to \((u(x,t), \rho(x,t))\).

On the other hand, any primary solution \(f(y,s)\) yields a solution of the 2-CH system in a parametric form through the formulae (2.17), (2.18). In the next theorem it will be shown that from a primary solution \(f(y,s)\) one can construct another solution of the 2-CH system. This solution is still in parametric form, however, in this case the function \(x = x(y,s)\) is given explicitly in terms of \(f(y,s)\) without the need of integration.

Due to (2.17), we can rewrite the equations of (2.18) in the form
\[
\frac{\partial x}{\partial y} = \frac{1}{f_s}, \quad \frac{\partial x}{\partial s} = f_y f_s + f_{ss} f_{ys} - f_{yss},
\]
(2.20)

By using the equations (2.15), (2.18) and the first equation of (2.10) we also have
\[
\frac{\partial f}{\partial s} = \frac{1}{x_y}, \quad \frac{\partial f}{\partial y} = \frac{m}{\rho^2} = \frac{u - u_{xx}}{\rho^2} = \frac{x_s x_y}{x_y} + \frac{x_{yy} x_{ys}}{x_y} - x_{yys}.
\]
(2.21)

The similarity of these equations suggests the existence of a duality between solutions of the equation (2.16). Indeed, we have the following theorem.

**Theorem 2.3** Let \(f(y,s)\) be a solution of the equation (2.16). Define the functions \(x = x(y,s), u = u(y,s), \rho = \rho(y,s)\) by
\[
x = f(s,y), \quad \frac{\partial x}{\partial s} = \frac{1}{\rho} = \frac{\partial x}{\partial y}.
\]
(2.22)

Then \((u(y,t), \rho(y,t), x(y,t))\) is a parametric solution of the 2-CH system (1.2), (1.3).

**Proof** Substituting \(u = \frac{\partial x}{\partial s}, \quad \frac{1}{\rho} = \frac{\partial x}{\partial y}\) into the equations (1.2), (1.3) we know, by using the relation (2.7), that \((u(y,t), \rho(y,t), x(y,t))\) gives a solution to the 2-CH system if and only if the function \(x(y,s)\) satisfies
\[
x_{ss} + \frac{2x_s x_{ys}}{x_y} + \frac{x_{yy}}{x_y} - \frac{x_{yys} x_{yy}}{x_y} + \frac{x_{ys} x_{yy}}{x_y} + \frac{x_{ys} x_{yy}}{x_y} - \frac{x_{yys} x_{yy}}{x_y} = 0.
\]
(2.23)

This equation follows immediately from the fact that the function \(f(y,s)\) satisfies (2.16). The theorem is proved.

Let us note that for the parametric solution (2.22), the associated primary solution \(\tilde{f}(y,s)\) that is determined by the formulae (2.10), (2.15) is in general different from the original primary solution \(f(y,s)\). This procedure yields a Bäcklund transformation \(f(y,s) \mapsto \tilde{f}(y,s)\) for the equation (2.16). We will consider in detail such a class of Bäcklund transformation for the equation (2.10) and the 2-CH system in another publication. In the next section, we will show how to construct primary solutions of the 2-CH system from solutions of the first negative flow of the AKNS hierarchy.

### 3 Relations to the first negative flow of the AKNS hierarchy

The AKNS spectral problem is given by
\[
\begin{pmatrix}
\phi_1 \\
\phi_2
\end{pmatrix}_y = \begin{pmatrix}
\lambda & -q \\
r & -\lambda
\end{pmatrix}
\begin{pmatrix}
\phi_1 \\
\phi_2
\end{pmatrix}.
\]
(3.1)

The first negative flow of the ANKS hierarchy is equivalent to the compatibility conditions of (3.1) with the linear system
\[
\begin{pmatrix}
\phi_1 \\
\phi_2
\end{pmatrix}_s = \frac{1}{4\lambda}
\begin{pmatrix}
a & b \\
c & -a
\end{pmatrix}
\begin{pmatrix}
\phi_1 \\
\phi_2
\end{pmatrix}.
\]
(3.2)
Due to (3.7) and (3.4), (3.5) we have

Proof gives a primary solution of the 2-CH system.

\[ y \]

Differentiating both sides of (3.8) w.r.t. \( y \), we obtain

\[ a^2 + bc = \varepsilon^2, \tag{3.6} \]

where \( \varepsilon \) is a constant. We assume that \( \varepsilon \neq 0 \).

**Theorem 3.1** Let \((a, b, c, q, r)\) be a solution of the equations (3.3)–(3.5) with \( \varepsilon^2 = 1 \), then any function \( f(y, s) \) satisfying

\[ 2a = b e^{-f} - c e^f \tag{3.7} \]

gives a primary solution of the 2-CH system.

*Proof* Assume that the function \( f = f(y, s) \) satisfies (3.7). Let us first prove the following formula:

\[ f_y = q e^{-f} + r e^f, \tag{3.8} \]

Due to (3.4) and (3.5), we have

\[
0 = (2a - be^{-f} + ce^f)y = 2ay - bye^{-f} + cye^f + (be^{-f} + ce^f)f_y \\
= -2(br + cq) - 2aqe^{-f} + 2are^f + (be^{-f} + ce^f)f_y \\
= -2(br + cq) - (be^{-f} - ce^f)(qe^{-f} - re^f) + (be^{-f} + ce^f)f_y \\
= (be^{-f} + ce^f)(f_y - qe^{-f} - re^f) \tag{3.9}
\]

The formula (3.8) then follows from (3.9) and the fact that

\[ be^{-f} + ce^f = \sqrt{(be^{-f} - ce^f)^2 + 4bc} = \sqrt{4(a^2 + bc)} = \pm 2\varepsilon \neq 0 \tag{3.10} \]

Differentiating both sides of (3.8) w.r.t. \( y \) and \( s \) we obtain respectively

\[
f_{yy} = (qe^{-f} + re^f)_y = q_y e^{-f} + r_y e^f - (qe^{-f} - re^f)f_y \\
= q_y e^{-f} + r_y e^f - (qe^{-f} - re^f)(qe^{-f} + re^f) \\
= q_y e^{-f} + r_y e^f - qe^{-2f} + re^{2f} \tag{3.11}
\]

\[
f_{ys} = (qe^{-f} + re^f)_s = q_s e^{-f} + r_s e^f - (qe^{-f} - re^f)f_s \\
= \frac{1}{2}be^{-f} + \frac{1}{2}ce^f - (qe^{-f} - re^f)f_s \tag{3.12}
\]

For any solution \((\phi_1 = \phi_1(y, s; \lambda), \phi_2 = \phi_2(y, s; \lambda))\) of the systems (3.3)–(3.5), define

\[ \varphi = e^{-f} \phi_1 + e^f \phi_2, \tag{3.13} \]

\[ P = f_y, \quad \rho = f_s, \tag{3.14} \]

\[ Q = -\frac{3}{4} e^{-2f} - \frac{1}{2} q r - \frac{3}{4} r^2 e^{2f} + \frac{1}{2} q y e^{-f} - \frac{1}{2} r y e^f. \tag{3.15} \]

By using equations (3.8) - (3.12) and the fact \( \varepsilon^2 = 1 \), we can show through a straightforward and lengthy computation that the functions \( \varphi, P, Q, \rho \) satisfy the equations (2.8), (2.9) and (2.14). To
Corollary 3.3

and the ones that are related to the isospectral problems (2.8). □
The theorem is proved.

The following theorem gives an explicit way of constructing a solution of the first negative flow of the AKNS hierarchy from a primary solution of the 2-CH system.

Theorem 3.2 If \( f \) is a primary solution of the 2-CH system (3.1), then we can construct a solution of the first negative flow of the AKNS hierarchy by the following formulae

\[
q = \frac{e^f}{2} \left( f_y + \frac{\varepsilon - f_{ys}}{f_s} \right), \quad r = \frac{e^{-f}}{2} \left( f_y - \frac{\varepsilon - f_{ys}}{f_s} \right), \quad b = 2qs, \quad c = 2rs, \quad a = \frac{be^{-f} - ce^{f}}{2}
\]  

where \( \varepsilon = 1 \) or \( \varepsilon = -1 \).

Proof Since \( f \) is a primary solution of the 2-CH system, we have \( E = 0 \) where \( E \) is defined as in the proof of Theorem 2.1. Then by a straightforward computation, we obtain

\[ b_y - 2a q = 2e^f E = 0, \quad c_y - 2a r = 2e^{-f} E = 0, \quad a^2 + bc = \varepsilon^2 = 1. \]  

The theorem is proved. □

By using the freedom in the choice of signs of the parameter \( \varepsilon \) we obtain the following corollary:

Corollary 3.3 We have the following two Bäcklund transformations for the equation (2.8)

\[
f \mapsto B_{\varepsilon} f = f + \log \left( \frac{f_{ss} f_{ys} + f_s^3 f_y - f_s f_{yys} + \varepsilon (f_{ss} - f_s^2)}{f_{ss} f_{ys} + f_s^3 f_y - f_s f_{yys} + \varepsilon (f_{ss} + f_s^2)} \right), \quad \varepsilon = 1 \text{ or } -1.
\]
Proof Since \( f \) is a primary solution of the 2-CH system, by using Theorem 3.2 we obtain two solutions of the first negative flow of the AKNS hierarchy, we denote them by \((a_\varepsilon, b_\varepsilon, c_\varepsilon, q_\varepsilon, r_\varepsilon), \varepsilon = 1, -1\). Due to Theorem 3.1, each of these two solutions yields two primary solutions of the 2-CH system

\[
f_{\varepsilon, \gamma} = \log \frac{\gamma - a_\varepsilon}{\varepsilon} = \log \frac{b_\varepsilon}{\gamma + a_\varepsilon}, \quad \varepsilon, \gamma = \pm 1.
\]  

(3.22)

It is easy to see that \( f_{\varepsilon, \gamma} = f \) when \( \gamma = \varepsilon \). The corollary is then proved if we identify \( B_\varepsilon f \) with \( f_{\varepsilon, -\varepsilon} \). \( \square \)

The Bäcklund transformations given by the above corollary can also be represented in terms of the dependent variables \( q, r \) of the first negative flow of the AKNS hierarchy, due to their long expressions we do not present the formulae here. Instead, let us illustrate the procedure of obtaining solutions of the system (3.3)–(3.5) starting from the following trivial solution:

\[
q = \sum_{i=1}^{n} e^{\zeta_i x + \xi_i + \zeta_i}, \quad r = 0, \quad b = 2qs, \quad c = 0, \quad a = \gamma,
\]  

(3.23)

where \( n \in \mathbb{N}, \zeta_i, \xi_i, \gamma \) are arbitrary constants with \( \zeta_i \) non-vanishing and pairwise distinct. According to Theorem 3.1 we know that \( f_0 = \log \frac{b}{\gamma + a} = \log \frac{qs}{\gamma} \) is a primary solution of the 2-CH system. By using the above corollary, we obtain two solutions of the equation (2.16), however, only one of them makes sense. By repeating this procedure, we obtain a sequence of primary solutions \( f_0, f_1, f_2, \ldots \) of the 2-CH system. Then by using Theorem 2.1 or Theorem 2.3 and Theorem 3.2, we obtain a sequence of solutions of the 2-CH system and the first negative flow of the AKNS hierarchy. Such class of solutions of the 2-CH system have very nice properties, we will study them in more detail in the next section.

4 Particular solutions of the 2-CH system

We are now ready to present in this section some examples of solutions of the 2-CH system, they include the peakon and multi-kink solutions.

Example 1. Let us first try, without referring to the reciprocal transformation constructed above, to find travelling wave solutions of the 2-CH system. Assume \( u = h(x + vt), \rho = g(x + vt) \), where \( v \) is a constant. Then the equation (1.2) and (1.3) become

\[
v(h' - h'''') + 3h h'' - 2h' h'' - h h''' + \kappa h' - g g' = 0, \quad (4.1)
\]

\[
v g' + g h' + h g' = 0. \quad (4.2)
\]

We can solve the second equation directly

\[
g = \frac{A}{v + h} \quad (4.3)
\]

where \( A \) is a constant. Then the equation (4.1) becomes an ODE for \( h \). This ODE can be solved by a standard method. By carefully choosing the integration constant, we obtain the following solution

\[
u = \chi - \sqrt{\chi^2 - v^2}, \quad \rho = \sqrt{vK} \left( 1 + \sqrt{\frac{\chi - v}{\chi + v}} \right), \quad \text{where} \quad \chi = (v - K) \cosh(x + vt) + K, \quad (4.4)
\]

where \( K = -4\kappa \). If \( v > 0, K > 0 \), this is a travelling peakon solution, see Figure 1.
**Example 2.** The first negative flow of the AKNS hierarchy has an important reduction. Under the assumption
\[ q = -\frac{w_y}{2}, \quad r = \frac{w_y}{2}, \quad b = -\sinh w, \quad c = \sinh w, \quad a = \cosh w, \quad (4.5) \]
it is reduced to the sinh-Gordon equation
\[ w_{ys} = \sinh w. \quad (4.6) \]

Now let us employ the results of the previous sections to obtain a stationary peakon solution of the 2-CH system (1.2) and (1.3) with \( \kappa = 0 \). Due to Theorem 3.1, a solution of the sinh-Gordon equation leads to a primary solution of the 2-CH system
\[ f(y,s) = \varepsilon \log \left( -\tanh \frac{w}{2} \right), \quad (4.7) \]
where \( \varepsilon = \pm 1 \).

Then the equations in (2.15) become
\[ P = \varepsilon \frac{w_y}{w_{ys}}, \quad \rho = \varepsilon \frac{w_s}{w_{ys}}. \quad (4.8) \]

By using Theorem 2.1, we find a parametric solution of the 2-CH system with \( \kappa = 0 \)
\[ x(y,s) = \varepsilon \log w_s + x_0, \quad u(y,s) = \varepsilon \frac{w_{ss}}{w_s}, \quad \rho = \varepsilon \frac{w_s}{w_{ys}}. \quad (4.9) \]
where \( x_0 \) is an arbitrary constant.

Now let us choose a kink solution of the sinh-Gordon equation
\[ w(y,s) = 4 \tanh^{-1} \left( e^{p_1 y + \frac{q_1}{p_1} q_1} \right), \quad (4.10) \]
with some constants \( p_1 \neq 0, q_1 \) and substitute it into (4.9), we obtain a stationary solution of the 2-CH system
\[ u = \frac{\sqrt{1 + e^{2r(x-x_0)}}}{p_1}, \quad \rho = \frac{1}{p_1 \sqrt{1 + e^{2r(x-x_0)}}}. \quad (4.11) \]

Then it is easy to see that the following \( u, \rho \)
\[ u = \frac{\sqrt{1 + e^{-2r(x-x_0)}}}{p_1}, \quad \rho = \frac{1}{p_1 \sqrt{1 + e^{-2r(x-x_0)}}}. \quad (4.12) \]
is a stationary peakon solution of the 2-CH system, see Figure 1. Note that a peakon solution with constant speed \(-\frac{1}{2} \kappa\) for the 2-CH system without the assumption of \( \kappa = 0 \) can be obtained by the Galilean transformation \( x \rightarrow \tilde{x} = x - \frac{1}{\frac{1}{2} \kappa} t, \quad t \rightarrow \tilde{t} = t, \quad u \rightarrow \tilde{u} = u - \frac{1}{\frac{1}{2} \kappa}, \quad \rho \rightarrow \tilde{\rho} = \rho \). If we choose \( w \) as a multi-kink solution of the sinh-Gordon equation, we will arrive at some very strange solutions of the 2-CH system whose peaked points are also stationary.

**Example 3.** In this example we give some explicit expressions of kink and 2-kink interaction solutions of the 2-CH system with \( \kappa = 0 \). These solutions are derived from the particular trivial solutions of the first negative flow of the AKNS hierarchy given in the end of the last section and by using the B"acklund transformations of Corollary 3.3. It’s easy to see that there are only constant solutions when \( n = 1 \). We consider here the cases when \( n = 2 \) and \( n = 3 \).

Let us first assume \( n = 2 \). Denote \( \xi_i = p_i y + \frac{q_i}{p_i}, \) then we have the following solution for the first negative flow of the AKNS hierarchy
\[ q = p_1 e^{\xi_1} + p_2 e^{\xi_2}, \quad r = 0, \quad b = 2(e^{\xi_1} + e^{\xi_2}), \quad c = 0, \quad a = 1, \quad (4.13) \]
where $p_1 \neq p_2$. By applying Theorem 3.1 and the Bäcklund transformations of Corollary 3.3 we arrive at the following two primary solutions of the 2-CH system

$$f_0 = \log (e^{\xi_1} + e^{\xi_2}), \quad f_1 = \log \left( \frac{(p_1 - p_2)^2 e^{\xi_1 + \xi_2}}{p_1^2 e^{2\xi_1} + p_2^2 e^{2\xi_2}} \right). \quad (4.14)$$

Note that a further application of the Bäcklund transformations of Corollary 3.3 leads to $f_2 = \log(0)$. So in this case we can only obtain two primary solutions. By using Theorem 2.3 we obtain two solutions of the 2-CH system which have the form (2.22) with the function $x(y, s)$ given respectively by

$$x_0 = \log (e^{\tilde{\xi}_1} + e^{\tilde{\xi}_2}), \quad x_1 = \log \left( \frac{(p_1 - p_2)^2 e^{\tilde{\xi}_1 + \tilde{\xi}_2}}{p_1^2 e^{2\tilde{\xi}_1} + p_2^2 e^{2\tilde{\xi}_2}} \right), \quad (4.15)$$

where $\tilde{\xi}_i = p_i s + \frac{\xi_i}{p_i} + q_i$. The solution obtained from $x_0$ (respectively, $x_1$) is an antikink (respectively, kink), see Figure 2 where the profiles of $\rho$ are represented by the dashed curves.

Now let us consider the case when $n = 3$, in a similar way to the previous case we obtain three solutions of the 2-CH system which have the form (2.22) with the function $x(y, s)$ given respectively by...
Figure 3: The interaction of two antikinks (4.16).

by

\[ x_0 = \log \left( e^{\xi_1} + e^{\xi_2} + e^{\xi_3} \right), \]  \hspace{1cm} (4.16)

\[ x_1 = \log \left( \frac{p_1^2(p_2-p_3)^2e^{\xi_2+\xi_3} + p_2^2(p_3-p_1)^2e^{\xi_1+\xi_3} + p_3^2(p_1-p_2)^2e^{\xi_1+\xi_2}}{p_1^2p_2^2e^{\xi_1} + p_2^2p_3^2e^{\xi_2} + p_3^2p_1^2e^{\xi_3}} \right), \]  \hspace{1cm} (4.17)

\[ x_2 = \log \left( \frac{(p_1-p_2)^2(p_2-p_3)^2(p_3-p_1)^2e^{\xi_1+\xi_2+\xi_3}}{p_1^2(p_2-p_3)^2e^{\xi_2+\xi_3} + p_2^2(p_3-p_1)^2e^{\xi_1+\xi_3} + p_3^2(p_1-p_2)^2e^{\xi_1+\xi_2}} \right), \]  \hspace{1cm} (4.18)

where \( p_1, p_2, p_3 \) are pairwise distinct. These solutions describe the antikink-antikink, antikink-kink and kink-kink interactions, see Figure 3, 4, 5. These figures are drawn with parameters

\[ p_1 = 1, \quad p_2 = 2, \quad p_3 = 3, \quad q_1 = 0, \quad q_2 = 0, \quad q_3 = 0 \]  \hspace{1cm} (4.19)

and only for \( u \), since the figures of \( \rho \) corresponding to the above three solutions of the 2-CH system are very similar to that of \( u \), like the figures of the single kink solutions drawn in Figure 2.

In general, for any \( n \in \mathbb{N} \) we expect to arrive at in this way \( n \) solutions of the 2-CH system, each of which is a \((n-1)\)-kink solution if we choose the parameters \( p_i, q_i \) in an appropriate way. They correspond to the interactions of \( k \) antikinks and \( n-1-k \) kinks with \( k = 0, \ldots, n-1 \). Except for the cases of \( n = 2, 3 \), we can also check this assertion for the case when \( n = 4 \). We will leave the analysis of the general case to a subsequent publication.

5 Conclusion

We have constructed an explicit reciprocal transformation between the 2-CH system (1.2), (1.3) and the first negative flow of the AKNS hierarchy (3.3)–(3.5) with \( \epsilon^2 = 1 \). The primary solution \( f(y, s) \)
Figure 4: The interaction of an antikink and a kink (4.17).

Figure 5: The interaction of two kinks (4.18).
satisfying the equation (2.16) plays a crucial role in this construction. This transformation comprises of two steps, the first step is the correspondence between solutions of the 2-CH system and the primary solutions satisfying (2.16), it is given by the formulae (2.10), (2.15) and Theorems 2.1, 2.3. The second step is the correspondence between solutions of the first negative flow of the AKNS hierarchy and the primary solutions of the 2-CH system, it is given by Theorems 3.1, 3.2. These correspondences are presented in simple and explicit forms, they enable us to obtain solutions of the 2-CH system from that of the first negative flow of the AKNS hierarchy, which includes in particular the well known sine-Gordon and the sinh-Gordon equations.

In terms of the primary solutions we also obtained in Sec.2 two kinds of Bäcklund transformations for the 2-CH system or the first negative flow of the AKNS hierarchy, and showed in Sec.4 that the Bäcklund transformations given in this section lead to interesting multi-kink solutions of the 2-CH system. It would be interesting to express in terms of the primary solutions of the 2-CH system the Bäcklund transformations of the AKNS hierarchy that are well known in the literature, see for example [17, 25].

We note that the travelling peakon solution of the 2-CH system that is given by the first example of Sec.4 assumes that the constant $K > 0$, when $K = 0$ it degenerates to a peakon solution of the Camassa-Holm equation (1.1). The existence of multi-kink solutions of the 2-CH system is also an interesting phenomenon for a system of hydrodynamic type with dispersive perturbation terms. We will return to analyze in a subsequent paper in more details the various properties of particular solutions of the 2-CH system, including the problem of existence of multi-peakon solutions. Although the 2-CH system that we considered here was derived from the problem of classification of deformations of bihamiltonian structures of hydrodynamic type, we do expect that it would find for itself physically important applications.
