In this paper, a stochastic chemostat model with variable yield and Contois growth function is investigated. The yield coefficient depends on the limiting nutrient, and the environmental noises are given by independent standard Brownian motions. First, the existence and uniqueness of global positive solution are proved. Second, by using stochastic Lyapunov function, Itô’s formula, and some important inequalities, stochastic characteristics for the stochastic model are studied, including the extinction of micro-organism, the strong persistence in mean of micro-organism, and the existence of a unique stationary distribution of the stochastic model. Third, the necessary condition of an optimal stochastic control for the stochastic model is established by Hamiltonian function. In addition, some numerical simulations are carried out to illustrate the theoretical results and the influence of the variable yield on the microorganism.

1. Introduction

The chemostat occupies a central place in mathematical ecology. It has been widely used in modeling natural ecosystems such as lakes and establishing waste-water treatment mathematical model. Many works related to the chemostat model have been published in the journal of mathematical, biological, and chemical engineering (see [1–5], etc.).

A large number of scholars are attracted to yield coefficient reflecting the conversion of nutrient to microorganism. Most of the models assume that the yield coefficient is a constant (see [1, 2]). Smith and Waltman [1] have described a chemostat model with constant yield as follows:

\[
\begin{align*}
S'(t) &= (S^0 - S(t))D - p(S, x) \frac{x(t)}{\gamma}, \\
x'(t) &= x(t)(p(S, x) - D),
\end{align*}
\]

(1)

where all the parameters are positive constants. \(S(t)\) and \(x(t)\) stand for the concentrations of the nutrient and the micro-organism at time \(t\) in culture vessel, respectively. \(S^0\) is the input nutrient concentration. \(D\) is the common dilution rate. \(\gamma\) is a “yield” constant. \(p(S, x)\) represents the growth function. Sun and Yin [2] and Wang et al. [3] have studied the chemostat model with Monod growth function. Bayen et al. [4] and Sun and Chen [5] have investigated the chemostat model with Contois growth function. Based on model (1), choosing Contois growth function \(p(S, x) = \frac{mS(t)}{kx(t) + S(t)} + S(t)\), the model takes the following form:

\[
\begin{align*}
S'(t) &= (S^0 - S(t))D - \frac{mS(t)}{kx(t) + S(t)} \frac{x(t)}{\gamma}, \\
x'(t) &= x(t)\left(\frac{mS(t)}{kx(t) + S(t)} - D\right),
\end{align*}
\]

(2)

where \(m > 0\) represents the maximal growth rate and \(k > 0\) stands for the growth coefficient of the Contois function.

However, experimental data indicate that a constant yield may fail to explain the observed oscillatory behavior in the vessel (see [6]). This leads to the formulation of the variable yield model, for example [7–9]. The chemostat model with variable yield takes the following form:
investigated the stochastic characteristics of these stochastic models. Therefore, it is valuable to investigate the stochastic characteristics of the stochastic chemostat model with variable yield and Contois growth function. On the other hand, the optimal control plays an important role in practical application [4, 22]. Many scholars have paid more attention to the optimal stochastic control problem, which covers all aspects of physics, biology, economics, etc. Ding et al. [23] have solved the distributed $H_{\infty}$ state estimation problem for a class of discrete time-varying nonlinear system with both stochastic parameters and stochastic nonlinearities. Guo et al. [24] have studied the near-optimal control of a stochastic SIRS epidemic model that includes a nonmonotone incidence rate. Framstad et al. [25] have proved a sufficient maximum principle for the optimal control of jump diffusions and showed its connections to dynamic programming and given applications to financial optimization problems in a market described by such processes. Thus, it is necessary to study the optimal stochastic control of a stochastic chemostat model. Throughout the whole paper, Lyapunov function, Itô formula, and other basic methods can be referred to these monographs [26–32].

This paper is organized as follows. In Section 2, the existence of the unique global positive solution for the model (4) is studied. In Section 3, the stochastic characteristics of the stochastic model (4) are investigated, including the extinction at an exponential rate of the microorganism, the strong persistence in the mean of the microorganism, and the stationary distribution of the model (4). In Section 4, the necessary condition of an optimal stochastic control for the stochastic model (4) is investigated, and the near-optimal stochastic control is mentioned. In Section 5, the numerical simulations conclude the paper, and the influence of the variable yield on the microorganism is explained by taking different parameters.

2. Preliminaries

First of all, the notations are described for the whole paper as follows:

(i) $\Omega$: a set of the elementary events
(ii) $\mathcal{F}$: a family of the subsets of $\Omega$
(iii) $\{\mathcal{F}_t\}_{t \geq 0}$ a family of increasing sub-$\sigma$–algebras of $\mathcal{F}$
(iv) $P(\omega)$: the probability of events $\omega$
(v) $EX$: the expectation of $X$
(vi) $\emptyset$: the empty set
(vii) $I_A$: the indicator function of a set $A$, i.e., $I_A(x) = 1$ if $x \in A$ or otherwise $0$
(viii) a.s.: almost surely
(ix) $E^n$: the $n$–dimensional Euclidean space
(x) $\mathbb{R}$: the set of all real numbers
(xi) $\mathbb{R}_+$: the set of all nonnegative real numbers, i.e., $\mathbb{R}_+ = [0, \infty)$
(xii) $\mathbb{R}_+^d$: $\{x \in \mathbb{R}^d: x_i > 0, 1 \leq i \leq d\}$, i.e. the positive cone

$$
\begin{align*}
S'(t) &= (S^0 - S(t))D - \frac{mS(t)}{kx(t) + S(t)} + \frac{x(t)}{A + BS(t)},
\end{align*}
$$

where $y(S) = A + BS$ is the variable yield which is considered in [9]. Both $A$ and $B$ are positive constants.

Actually, the above models are all deterministic models, but almost all ecosystems are inevitably perturbed by various types of environmental noises. Taking into account the realistic and biological significance, many scholars have investigated stochastic chemostat models (see [3, 10–14]) and stochastic population models (see [15–19]). In the chemostat model, the micro-organism may be affected by distribution of nutrient, temperature, humidity, etc, which can be described by continuous white noise. There are different possible approaches to include random effects in the model, both from a biological and a mathematical perspective. Some authors have superimposed white noise processes on the dilution rate [20]; others have considered the linear white noise [11, 21]. Our basic approach is analogous to that of Beddington and May [21]. By this method, the white noise are directly proportional to $S(t)$ and $x(t)$, influenced on $S'(t)$ and $x'(t)$. A stochastic chemostat model with variable yield and Contois growth function will be investigated, and the model (3) will be rewritten as the form:

$$
\begin{align*}
\text{d}S(t) &= \left((S^0 - S(t))D - \frac{mS(t)}{kx(t) + S(t)} + \frac{x(t)}{A + BS(t)}\right)\text{d}t \\
&\quad + \sigma_1 S(t)\text{d}B_1(t),
\end{align*}
$$

$$
\begin{align*}
\text{d}x(t) &= x(t)\left(\frac{mS(t)}{kx(t) + S(t)} - D\right)\text{d}t + \sigma_2 x(t)\text{d}B_2(t),
\end{align*}
$$

where $\sigma_i > 0$ ($i = 1, 2$) are intensities of the white noise. $B_i(t)$ ($i = 1, 2$) are independent standard Brownian motions defined on a complete probability space $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}_{t \geq 0}, P)$ with the filtration $\{\mathcal{F}_t\}_{t \geq 0}$ satisfying the usual conditions. The model (4) turns into the corresponding deterministic model (3) if the noise intensities $\sigma_i = 0$ ($i = 1, 2$).

The initial conditions of (4) are given as

$$
\begin{align*}
S(0) &= S_0, \\
x(0) &= x_0,
\end{align*}
$$

where $S_0, x_0$ are positive random variables, and denote $\mathbb{R}_+^2 = \{(x_1, x_2) | x_i > 0, i = 1, 2\}$.

Because the solutions of the deterministic model (3) are no longer the solutions of the stochastic model (4), the dynamic behavior of the deterministic model (3) is distinct from that of the stochastic model (4). For further details on the stochastic model, please see [10–14], they have investigated the stochastic characteristics of these stochastic models. However, the nonlinear term of the model (4) is different from that of their models.

Complexity
(xiii) $U$: an open domain
(xiv) $\overline{U}$: a close domain

In view of biological significance and dynamical behavior, the first concerned thing is whether the solution is unique, global, and positive. Hence, to further study the stochastic chemostat model with variable yield and Contois growth function (4), the first problem to be solved is the existence of the unique global positive solution, namely, there is no explosion in a finite time under the initial value (5). If the coefficients of the equations are generally required to satisfy the linear growth condition and the local Lipschitz condition (see [28, 30]), the stochastic differential equations for any given initial value have a unique global solution. However, the stochastic model (4) may allow the solutions to explode at a finite time because the coefficients of the stochastic model (4) do not satisfy the linear growth condition. So, we need to search for the positive solutions. The following theorem assures that the solution of the model (4) with the initial value (5) is unique, global, and positive. First, a lemma and a remark are given.

**Lemma 1** (see [19]). The following inequality holds:
\[ u \leq 2 (u + 1 - \ln u) - (4 - 2 \ln 2), \forall u > 0. \]  
(6)

**Remark 1.** Based on Lemma 1, since the inequality \( u \leq 2 (u + 1 - \ln u) - (4 - 2 \ln 2) \) holds for all \( u > 0 \), the existence of the unique global positive solution for the model (4) is proved.

**Theorem 1.** For any initial value \( (S_0, x_0) \in \mathbb{R}^2 \), there exists a unique positive solution \( (S(t), x(t)) \) to the model (4) for \( t \geq 0 \), and the solution will remain in \( \mathbb{R}^2_+ \) with probability one (i.e., \( (S(t), x(t)) \in \mathbb{R}^2_+ \) for all \( t \geq 0 \) a.s.).

**Proof.** Since the coefficients of the stochastic differential equations (4) satisfy the local Lipschitz condition, the model (4) has a unique positive local solution \( (S(t), x(t)) \) on \( t \in [0, \tau_e] \) for any initial value \( (S_0, x_0) \in \mathbb{R}^2_+ \), where \( \tau_e \) is the explosion time. In order to show the solution is global, we just need to prove that \( \tau_e = \infty \) a.s. Select \( k_0 \geq 1 \) sufficiently large such that \( S_0 \) and \( x_0 \) all lie within the interval \( [(1/k_0), k_0] \). For \( \forall k \geq k_0 \), where \( k \) is a integer, the defining time \( \tau_k \) is \( \inf \{ t \in [0, \tau_e) \mid S(t) \notin \left( \frac{1}{k}, k \right) \) or \( x(t) \notin \left( \frac{1}{k}, k \right) \}. \)

(7)

Throughout this paper, we set \( \inf \emptyset = \infty \). \( \tau_k \) is increasing when \( k \to \infty \). Let \( \tau_{\infty} = \lim_{k \to \infty} \tau_k \), clearly, \( \tau_{\infty} \leq \tau_e \) a.s. \( \tau_e = \infty \) and \( (S(t), x(t)) \in \mathbb{R}^2_+ \) a.s. for all \( t \geq 0 \) if \( \tau_{\infty} = \infty \) can be verified. Next, for \( \tau_{\infty} = \infty \), the proof process is as follows:

Define a $C^2$–function $V: \mathbb{R}^2_+ \to \mathbb{R}_+$ by
\[ V(S, x) = S + 1 - \ln S + x + 1 - \ln x, \]
(8)
for \( \forall T > 0 \), by applying Itô’s formula on \( t \in [0, \tau_k \wedge T] \), we have
\[ \frac{dV(S, x)}{dt} = \left( 1 - \frac{1}{S} \right) \frac{dS}{dt} + \left( 1 - \frac{1}{x} \right) \frac{dx}{dt} + \frac{1}{2} \left( \frac{1}{S^2} \right)^2 (dS)^2 + \frac{1}{2} \left( \frac{1}{x^2} \right)^2 (dx)^2 \]
\[ = \left( \frac{mS}{kx + S} - \frac{S_0}{S} \right) \frac{dS}{dt} + \frac{mx}{(kx + S)(A + BS)} \]
\[ + \left( x - 1 \right) \frac{S_0}{S} + D + \frac{1}{2} (\sigma_1^2 + \sigma_2^2) dt + \sigma_1 \]
\[ \cdot \left( S - 1 \right) dB_1(t) + \sigma_2 \left( x - 1 \right) dB_2(t) \]
\[ = LV dt + \sigma_1 (S - 1) dB_1(t) + \sigma_2 (x - 1) dB_2(t), \]
(9)
by using Lemma 1
\[ LV = \frac{mS}{kx + S} - \frac{S_0}{S} \]
\[ + \frac{mx}{(kx + S)(A + BS)} \]
\[ - x D + \frac{mS}{kx + S} + D + \frac{1}{2} \sigma_1^2 + \frac{1}{2} \sigma_2^2 \]
\[ \leq \frac{S_0}{S} + 2 D + \frac{1}{2} \sigma_1^2 + \frac{1}{2} \sigma_2^2 + \frac{mx}{(kx + S)(A + BS)} + \frac{mS}{kx + S} \]
\[ \leq \frac{S_0}{S} + 2 D + \frac{1}{2} \sigma_1^2 + \frac{1}{2} \sigma_2^2 + \frac{m}{kA} \]
\[ \leq \frac{S_0}{S} + 2 D + \frac{1}{2} \sigma_1^2 + \frac{1}{2} \sigma_2^2 + \frac{m}{kA} + 2m x + 1 - \ln x \]
\[ + 2 (S + 1 - \ln x) \]
\[ \equiv N_1 + N_2 V(S, x), \]
(10)
so,
\[ \frac{dV(S, x)}{dt} \leq \left( N_1 + N_2 V(S, x) \right) dt + \sigma_1 (S - 1) dB_1(t) \]
\[ + \sigma_2 (x - 1) dB_2(t), \]
(11)
where
\[ N_1 = \frac{S_0}{S} + 2 D + \frac{1}{2} \sigma_1^2 + \frac{1}{2} \sigma_2^2 + \frac{m}{kA} \]
\[ N_2 = 2m \sqrt{2}. \]
(12)
Integrating equation (11) both sides from 0 to \( \tau \wedge T \) and taking expectation,
\[ EV (S(\tau \wedge T), x(\tau \wedge T)) \leq V(S_0, x_0) + N_1 T + N_2 E \int_0^{\tau \wedge T} V(S(t), x(t)) dt. \]
(13)
By using Gronwall’s inequality, we have
\[ EV (S(\tau \wedge T), x(\tau \wedge T)) \leq (V(S_0, x_0) + N_1 T) e^{N_2 T}. \]
(14)
For \( \forall \omega \in \{ \tau_k \leq T \} \), it exists that \( S(\tau_k, \omega) \) or \( x(\tau_k, \omega) \) equals either \( k \) or \((1/k)\),

\[
V(S(\tau_k, \omega), x(\tau_k, \omega)) \geq (k + 1 - \ln k) \left( \frac{1}{k} + 1 + \ln k \right)
\]  
\[
\equiv G(k).
\]  

(15)

Thus,

\[
(V(S_{0, x_0} + N_1 t)e^{N_2 t}) \geq \mathbb{E} \left[ I_{\{ \tau_k \leq T \}} (\omega)V(S(\tau_k, \omega), x(\tau_k, \omega)) \right] \geq \mathbb{P}[\tau_k \leq T]G(k),
\]  

(16)

where \( I_{\{ \tau_k \leq T \}} \) is the indicator function of \( \{ \tau_k \leq T \} \).

Letting \( k \to \infty \) gives \( \lim_{k \to \infty} \mathbb{P}[\tau_k \leq T] = 0 \), and hence, \( \mathbb{P}[\tau_\infty \leq T] = 0 \). Since \( T > 0 \) is arbitrary, we must have

\[
\mathbb{P}[\tau_\infty < \infty] = 0,
\]  

(17)

so \( \mathbb{P}[\tau_\infty = \infty] = 1 \) as required.

The proof is thus complete.

\[ \Box \]

3. Stochastic Characteristics

In this section, the stochastic characteristics of the stochastic model (4) are discussed. As is known to all, the equilibriums of the deterministic model (3) are no longer the equilibriums of the stochastic model (4), then what happens in the stochastic model (4)? Next, the sufficient conditions of the extinction and persistence of microorganism and the stationary distribution of the model (4) are investigated.

In order to study the model (4), we introduce the following definitions and lemmas, and denote \( \langle x \rangle = (1/t) \int_0^t x(s)ds \).

Lemma 2 (see [14]). For any initial value (5), the solutions \( S(t) \) and \( x(t) \) of the model (4) have the properties that

\[
\limsup_{t \to \infty} S(t) < \infty,
\]  

\[
\limsup_{t \to \infty} x(t) < \infty,
\]  

(18)

\( \text{a.s.} \).

That is, there are two positive constants \( H_1 \) and \( H_2 \) such that

\[
S(t) \leq H_1,
\]  

\[
x(t) \leq H_2,
\]  

for all \( t \geq 0 \),

\( \text{a.s.} \).

Lemma 3 (see [28]). Let \( M = \{ M_t \}_{t \geq 0} \) be a real-valued continuous local martingale vanishing at \( t = 0 \). Then

\[
\limsup_{t \to \infty} \frac{\langle M, M \rangle_t}{t} < \infty, \quad \text{a.s.}
\]  

(20)

\[
\Rightarrow \lim_{t \to \infty} \frac{M_t}{t} = 0, \quad \text{a.s.}
\]  

Next, the extinction at an exponential rate of the microorganism is studied.

Theorem 2. If the condition holds,

\[
\sigma^2 > 2(m - D),
\]  

(21)

then for any initial value (5), the solution \( (S(t), x(t)) \) of the model (4) satisfies

\[
\limsup_{t \to \infty} \frac{\ln x(t)}{t} \leq m - D - \frac{1}{2} \sigma^2 < 0, \quad \text{a.s.},
\]  

(22)

which means

\[
\lim_{t \to \infty} x(t) = 0, \quad \text{a.s.}
\]  

(23)

That is, the microorganism will be extinct at an exponential rate with probability one.

Proof. Define a function

\[
V = \ln x,
\]  

(24)

using Itô formula

\[
dV = \left( \frac{mS}{kx + S} - D - \frac{1}{2} \sigma^2 \right) dt + \sigma dB(t)
\]  

\[
\leq \left( m - D - \frac{1}{2} \sigma^2 \right) dt + \sigma dB(t), \quad \text{a.s.}
\]  

(25)

Integrating both sides from 0 to \( t \), we can obtain

\[
\frac{V(t) - V(0)}{t} \leq m - D - \frac{1}{2} \sigma^2 + \frac{\sigma x_0}{t} B(t),
\]  

(26)

then

\[
\frac{\ln x(t)}{t} \leq m - D - \frac{1}{2} \sigma^2 + \phi_1(t), \quad \text{a.s.,}
\]  

(27)

where

\[
\phi_1(t) = \frac{\sigma x_0}{t} B(t) + \frac{\ln x_0}{t},
\]  

(28)

\[
\lim_{t \to \infty} \phi_1(t) = 0,
\]  

\( \text{a.s.} \).

According to equation (27), we have

\[
\limsup_{t \to \infty} \frac{\ln x(t)}{t} \leq m - D - \frac{1}{2} \sigma^2 < 0, \quad \text{a.s.},
\]  

(29)

which implies that

\[
\lim_{t \to \infty} x(t) = 0, \quad \text{a.s.}
\]  

(30)

Thus, the proof is completed.

\[ \Box \]
Remark 2. Theorem 2 shows that the condition \( \sigma^2 > 2(m - D) \) makes the microorganism extinct, but it has nothing to do with \( m < D \) or \( m > D \), which means that large noises can lead to the extinction of the microorganism, although the microorganism is persistent in the corresponding deterministic model (3) (see Figures 1 and 2).

A definition and a lemma are given before discussing the strong persistence in the mean of the microorganism.

Definition 1 (see [17]). The population \( x(t) \) is said to be strong persistence in the mean if

\[
\langle x \rangle > 0, \quad (31)
\]

where \( \langle x \rangle = \liminf_{t \to \infty} \langle x \rangle \).

Lemma 4 (see [18]). Let \( f \in C[0, \infty] \times \Omega, (0, \infty) \). If there exist positive constants \( \lambda_0, \lambda \) such that

\[
\ln f(t) \geq \lambda t - \lambda_0 \int_0^t f(s)ds + F(t), \quad \text{a.s.,} \quad (32)
\]

for all \( t \geq 0 \), where \( F \in C[0, \infty] \times \Omega, \mathbb{R} \) and

\[
\lim_{t \to \infty} (F(t)/t) = 0, \quad \text{a.s., then} \quad \langle f \rangle > \frac{\lambda}{\lambda_0}, \quad \text{a.s.} \quad (33)
\]

Theorem 3. For any initial value (5), if the condition holds:

\[
\frac{1}{2} \sigma^2 < \xi \triangleq \min \left\{ \frac{m}{kH_2 + 1} - D, \frac{mS^0}{kH_2 + 1} - D \right\}, \quad (34)
\]

then the solution \( (S(t), x(t)) \) of the model (4) satisfies

\[
\langle x(t) \rangle > \frac{A D(kH_2 + 1)}{m(m + A \xi)} \left( \frac{\xi}{\sigma^2} \right) > 0. \quad (35)
\]

That is, the microorganism is almost surely strongly persistent in the mean.

Proof. On the one hand, based on the model (4), we have

\[
d(S + x) = \left( S^0 D - S D - \frac{mSx}{(kx + S)(A + BS)} + \frac{mSx}{kx + S} - x D \right) dt + \sigma_1 S dB_1(t) + \sigma_2 x dB_2(t)
\]

\[
\geq \left( S^0 D - S D - \frac{mSx}{A} - x D \right) dt + \sigma_1 S dB_1(t) + \sigma_2 x dB_2(t)
\]

\[
= \left( S^0 D - S D - \frac{m + AD}{A} x \right) dt + \sigma_1 S dB_1(t) + \sigma_2 x dB_2(t),
\]

so,

\[
S(t) + x(t) - S^0 \frac{t}{D} - x_0 \geq S^0 D - D \langle S(t) \rangle - \frac{m + AD}{A} \langle x(t) \rangle + \frac{\sigma_1}{t} M_1(t) + \frac{\sigma_2}{t} M_2(t),
\]

where

\[
M_1(t) = \int_0^t S(s)dB_1(s),
\]

\[
M_2(t) = \int_0^t x(s)dB_2(s).
\]

Thus,

\[
\langle S(t) \rangle \geq S^0 - \frac{m + AD}{A} \langle x(t) \rangle - \varphi_2(t), \quad (39)
\]

where

\[
\varphi_2(t) = \frac{1}{D} \left( S(t) + x(t) - S^0 \frac{t}{D} - x_0 - \frac{\sigma_1}{t} M_1(t) - \frac{\sigma_2}{t} M_2(t) \right).
\]

Since \( M_1(t) \) and \( M_2(t) \) are local continuous martingales with \( M_1(0) = 0 \) and \( M_2(0) = 0 \), from Theorem 5.14 in Mao’s monograph [28], Lemmas 2 and 3, we have

\[
\limsup_{t \to \infty} \frac{\langle M_1, M_1 \rangle}{t} = \int_0^t S^2(s)ds \leq H^2 \text{ for some } H, \quad (41)
\]

\[
\limsup_{t \to \infty} \frac{\langle M_2, M_2 \rangle}{t} = \int_0^t x^2(s)ds \leq H^2 \text{ for some } H, \quad (42)
\]

On the other hand, we will discuss the long time behavior of the microorganism \( x \) in two cases, we define

\[
V = \ln x. \quad (43)
\]

Case 1. If \( S(t) < 1 \), we get

\[
dV = \left( \frac{ms}{kx + S} - D - \frac{1}{2} \sigma^2 \right) dt + \sigma_2 dB_2(t)
\]

\[
\geq \left( \frac{ms}{kH_2 + 1} - D - \frac{1}{2} \sigma^2 \right) dt + \sigma_3 dB_2(t),
\]

so,

\[
\frac{V(t) - V(0)}{t} \geq \frac{m}{kH_2 + 1} \langle S(t) \rangle - D - \frac{1}{2} \sigma^2 + \frac{\sigma_3}{t} B_2(t). \quad (45)
\]
Substituting (39) into (45), we obtain

\[
\frac{V(t) - V(0)}{t} \geq \frac{m}{kH_2 + 1} \left( S^0 - \frac{m + A}{A} D \right) \langle x(t) \rangle - \frac{\sigma_2}{2} B_2(t) \]

\[
- D - \frac{1}{2} \sigma_2^2 + \frac{\sigma_2}{t} B_2(t).
\]

(46)

When \( S^0 < 1 \), we have

\[
\ln x(t) \geq \left( \frac{mS^0}{kH_2 + 1} - D - \frac{1}{2} \sigma_2^2 \right) t - \frac{m(m + A)}{A} \frac{D}{D(kH_2 + 1)} \langle x(t) \rangle t
\]

\[+ \frac{m t \varphi_2(t)}{kH_2 + 1} + \sigma_2 B_2(t) + \ln x_0
\]

\[\pm \lambda_1 t - \lambda_0 \int_0^t x(s) ds + F_1(t),
\]

(47)

where

Figure 1: The solutions of deterministic model (3) and stochastic model (4). (a) Sample paths of \( S(t) \) with \( A = 2, B = 0 \). (b) Sample paths of \( x(t) \) with \( A = 2, B = 0 \). (c) Sample paths of \( S(t) \) with \( A = 2, B = 3 \). (d) Sample paths of \( x(t) \) with \( A = 2, B = 3 \).
\[
\lambda_1 = \frac{mS^0}{kH_2 + 1} - D - \frac{1}{2}\sigma_2^2,
\]
\[
\lambda_0 = \frac{m(m + AD)}{AD(kH_2 + 1)},
\]
\[
F_1(t) = \frac{mt\varphi_2(t)}{kH_2 + 1} + \sigma_2B_2(t) + \ln x_0,
\]

When \( S^0 \geq 1 \), we have
\[
\ln x(t) \geq \left( \frac{m}{kH_2 + 1} - D - \frac{1}{2}\sigma_2^2 \right) t - \frac{m(m + AD)}{AD(kH_2 + 1)} \langle x(t) \rangle t - \frac{mt\varphi_2(t)}{kH_2 + 1} + \sigma_2B_2(t) + \ln x_0
\]
\[
\geq \lambda_2 t - \lambda_0 \int_0^t x(s)ds + F_1(t),
\]

where \( \lambda_2 = (m/kH_2 + 1) - D - (1/2)\sigma_2^2 \), similar to the above, we can obtain that

Figure 2: The solutions of deterministic model (3) and stochastic model (4). (a) Sample paths of \( S(t) \) with \( A = 2, B = 0 \). (b) Sample paths of \( x(t) \) with \( A = 2, B = 0 \). (c) Sample paths of \( S(t) \) with \( A = 2, B = 3 \). (d) Sample paths of \( x(t) \) with \( A = 2, B = 3 \).
\[ \langle x(t) \rangle \geq \frac{A}{m(m + A)} \frac{D(kH_2 + 1)}{D} \left( \frac{m}{kH_2 + 1} - D - \frac{1}{2} \sigma_2^2 \right) > 0. \] (51)

**Case 2.** If \( S(t) \geq 1 \), we get
\[ dV = \left( \frac{mS}{kx + S} - D - \frac{1}{2} \sigma_2^2 \right) dt + \sigma_2 dB_2(t) \]
\[ \geq \left( \frac{m}{kH_2 + 1} - D - \frac{1}{2} \sigma_2^2 \right) dt + \sigma_2 dB_2(t), \]
so,
\[ \frac{V(t) - V(0)}{t} \geq \frac{m}{kH_2 + 1} - D - \frac{1}{2} \sigma_2^2 + \frac{\sigma_2^2}{t} B_2(t). \] (53)

Obviously,
\[ \frac{V(t) - V(0)}{t} \geq \frac{m}{kH_2 + 1} - D - \frac{1}{2} \sigma_2^2 - \frac{m(m + A)}{A D(kH_2 + 1)} \langle x(t) \rangle t \]
\[ + \frac{\sigma_2^2}{t} B_2(t). \] (54)

When \( S^0 < 1 \), we have
\[ \ln x(t) \geq \frac{mS}{kH_2 + 1} - D - \frac{1}{2} \sigma_2^2 \frac{t}{t} - \frac{m(m + A)}{A D(kH_2 + 1)} \langle x(t) \rangle t \]
\[ + \sigma_2 B_2(t) + \ln x_0, \]
\[ \equiv \lambda_1 t - \lambda_0 \int_0^t x(s) ds + F_2(t), \] (55)

where \( F_2(t) = \sigma_2 B_2(t) + \ln x_0 \), similarly, we have
\[ \langle x(t) \rangle \geq \frac{A}{m(m + A)} \frac{D(kH_2 + 1)}{D} \left( \frac{mS}{kH_2 + 1} - D - \frac{1}{2} \sigma_2^2 \right) > 0. \] (56)

When \( S^0 \geq 1 \), we have
\[ \ln x(t) \geq \left( \frac{m}{kH_2 + 1} - D - \frac{1}{2} \sigma_2^2 \right) t - \frac{m(m + A)}{A D(kH_2 + 1)} \langle x(t) \rangle t \]
\[ + \sigma_2 B_2(t) + \ln x_0, \]
\[ \equiv \lambda_2 t - \lambda_0 \int_0^t x(s) ds + F_2(t), \] (57)

Similar to the above, we have
\[ \langle x(t) \rangle \geq \frac{A}{m(m + A)} \frac{D(kH_2 + 1)}{D} \left( \frac{m}{kH_2 + 1} - D - \frac{1}{2} \sigma_2^2 \right) > 0. \] (58)

In conclusion, no matter what \( S(t) \) chooses, we have
\[ \langle x(t) \rangle > 0. \] (59)

This completes the proof of Theorem 3.

**Remark 3.** It follows from Theorem 3 that the microorganism will be strongly persistent in the mean if the condition \((1/2) \sigma_2^2 < \xi \min (m(kH_2 + 1) - D, (mS^0/kH_2 + 1) - D)\) is satisfied. That is, when the intensity of the white noise is small enough, the microorganism will survive (see Figures 3 and 4).

Stationary distribution is one of the most significant dynamical characteristics of the stochastic model; that is, the stochastic model has a stationary distribution which represents the persistence of microorganism in the future. Therefore, in the rest of this section, we will make a positive decision by the existence of the stationary distribution. Before proving the main result, several known results are given for the stochastic differential equations.

Assume \( X(t) \) is a regular time-homogeneous Markov Process in \( n \)-dimensional Euclidean space \( E^n \). The stochastic differential equation takes the following form:
\[ dX(t) = h(X) dt + \sum_{i=1}^{n} g_i(X) dB_i(t). \] (60)

The diffusion matrix of the process \( X(t) \) is defined as follows:
\[ \alpha_i(x) = \left( \alpha_{ij}(x) \right), \]
\[ \alpha_{ij}(x) = \sum_{i=1}^{n} g_i^j(x) g_i^j(x). \] (61)

Define the differential operator \( L \) associated with (60) by
\[ L = \frac{\partial}{\partial t} + \sum_{i=1}^{n} h_i(x) \frac{\partial}{\partial x_i} + \frac{1}{2} \sum_{i,j=1}^{n} \alpha_{ij}(x) \frac{\partial^2}{\partial x_i \partial x_j}. \] (62)

**Lemma 5** (see [30]). Assume that there exists a bounded open domain \( U \subset E^n \) with regular boundary \( \Gamma \), having the following properties:

1. In the domain \( U \) and some neighborhood thereof, the smallest eigenvalue of the diffusion matrix \( \alpha \) is bounded away from zero.
2. If \( x \in E^n \setminus U \), the mean time \( \tau \) at which a path issuing from \( x \) reaches the set \( U \) is finite, and \( \sup_{x \in \mathbb{K}} E^\tau \tau < \infty \) for every compact subset \( \mathbb{K} \subset E^n \).

Then the Markov process \( X(t) \) has a stationary distribution \( \mu (\cdot) \), and it is unique.

**Remark 4.** Since we investigate the stochastic model (4) in the space \( \mathbb{R}_+^2 \), to validate condition (1) of Lemma 5, we need to prove that for any bounded open domain \( U \subset \mathbb{R}_+^2 \), there is a positive number \( M \) such that \( \sum_{i,j=1}^{n} \alpha_{ij}(x) \xi_i \xi_j \geq M \xi^2 \), \( x \in \mathbb{K} \subset \mathbb{R}_+^2 \) (see [31, 32]). To validate condition (2) of Lemma 5, we need to show that there exists a neighborhood \( U \) and a non-negative \( C^2 \)-function \( V \) such that for any \((S, x) \in \mathbb{R}_+^2 \setminus U, LV \) is negative.
The following theorem shows that the model (4) has a unique stationary distribution for any given initial value (5).

**Theorem 4.** Let \( \eta = c_2S^0D - (c_1mS^0/kA) - (c_1\sigma S^2/2) - D - (\sigma^2/2) \) where \( c_2 = (mkH_2/D(kH_2 + S^0)^3) \). If there exists a constant \( c_1 > (mkH_2S^0/D(kH_2 + S^0)^3) \) such that \( \eta \) is positive, then for any given initial value (5), the solution of the model (4) admits a unique stationary distribution \( \mu(\cdot) \).

**Proof.** According to the model (4), we get

\[
\begin{pmatrix}
\frac{d S}{dt} \\
\frac{d x}{dt}
\end{pmatrix} = \begin{pmatrix}
(S^0 - S)D - \frac{mSx}{kx + S}(A + BS) \\
\frac{mSx}{kx + S} - x \quad D
\end{pmatrix} dt + \begin{pmatrix}
\sigma_1 S \\
0
\end{pmatrix} dB_1(t) + \begin{pmatrix}
0 \\
\sigma_2 x
\end{pmatrix} dB_2(t)
\]  

So, the diffusion matrix is
Let $U$ be any bounded open domain in $\mathbb{R}^2_+$, then there exists a positive constant
\[ M_0 = \min\{\sigma_1^2 S^2, \sigma_2^2 x^2, (S, x) \in U\}, \]
such that
\[ \sum_{i,j=1}^2 a_{ij}(S, x)\xi_i \xi_j = \sigma_1^2 S^2 \xi_1^2 + \sigma_2^2 x^2 \xi_2^2 \geq M_0 |\xi|^2, \]
for all $(S, x) \in \overline{U}, \xi \in \mathbb{R}^2_+$, which implies that condition (1) of Lemma 5 is satisfied.

Next, we need to construct a non-negative $C^2$-function $V(S, x)$ and a open set $U \in \mathbb{R}^2_+$, such that
\[ \sup_{(S, x) \in \mathbb{R}^2_+ \setminus U} LV(S, x) < 0. \]

Then, we select $\theta \in (0,1)$ to be a sufficiently small constant such that
\[ (A.1) \, D - \frac{\theta}{2} (\sigma_1^2 + \sigma_2^2) > 0, \]
choosing a large enough positive constant $N$ such that
\[ (A.2) \, \psi'_1 - N\eta \leq -2, \]
where $\psi'_1 = \sup_{(S, x) \in \mathbb{R}^2_+ \setminus U} \psi_1(S, x)$, and $\psi_1(S, x)$ is given in (A.3).

Figure 4: The solutions of deterministic model (3) and stochastic model (4). (a) Sample paths of $S(t)$ with $A = 2, B = 0$. (b) Sample paths of $x(t)$ with $A = 2, B = 0$. (c) Sample paths of $S(t)$ with $A = 2, B = 3$. (d) Sample paths of $x(t)$ with $A = 2, B = 3$. 
Define a nonnegative $C^2$-Lyapunov function

$$V(S,x) = H(S,x) - H(S_0,x_0),$$

(70)

where $H(S,x) = NV_1 + V_2 + V_3$, $V_1 = c_1 \left( S - S^0 - S^0 \ln(S/S^0) \right), V_2 = (1/((\theta + 1)) (S + x)^{\theta + 1}, V_3 = -\ln S$, and $H(S,x)$ is a $C^2$-function with a unique minimum value point $(S_0,x_0)$. Using Itô formula for $V_1, V_2, V_3$, we estimate $LV_1$ firstly.

$$d\left(S - S^0 - S^0 \ln \frac{S}{S^0}\right) = \left(-\frac{(S - S^0)^2}{S} - mx(S - S^0) \frac{1}{(kx + S)(A + BS)} + \frac{1}{2} \sigma_1^2 S^0 \right) dt + \sigma_1(S - S^0) dB_1(t),$$

$$d(\ln x) = \left( \frac{mS}{kx + S} - D - \frac{1}{2} \sigma_2^2 \right) + \sigma_2 dB_2(t),$$

$$d(S + x) = \left( (S - S^0)D - \frac{mSx}{kx + S} + \frac{mSx}{kx + S} - x \right) dt + \sigma_1 dB_1(t) + \sigma_2 x dB_2(t).$$

So,

$$dV_1 = c_1 \left( -\frac{(S - S^0)^2}{S} - mx(S - S^0) \frac{1}{(kx + S)(A + BS)} + \frac{1}{2} \sigma_1^2 S^0 \right) dt - \left( \frac{mS}{kx + S} - D - \frac{1}{2} \sigma_2^2 \right) dt$$

$$- c_2 \left( (S - S^0)D - \frac{mSx}{kx + S} + \frac{mSx}{kx + S} - x \right) dt$$

$$+ c_1 \sigma_1(S - S^0) dB_1(t) - \sigma_3 dB_2(t) - c_2 (\sigma_1 dB_1(t) + \sigma_2 x dB_2(t)),$$

thus,

$$LV_1 = \left(-\frac{c_1 D(S - S^0)^2}{S} - \frac{c_1 mx(S - S^0)}{(kx + S)(A + BS)} + \frac{c_1 \sigma_1^2 S^0}{2} - \frac{mS}{kx + S} + D + \frac{1}{2} \sigma_2^2\right)$$

$$- c_2 D(S^0 - S) + \frac{c_2 mSx}{(kx + S)(A + BS)} - \frac{c_2 mSx}{kx + S} + c_2 D x$$

$$\leq -\frac{c_1 D(S - S^0)^2}{S} + \frac{c_1 mS^0}{kA} + \frac{c_1 \sigma_1^2 S^0}{2} - \frac{mS}{kH_2 + S} + D + \frac{1}{2} \sigma_2^2$$

$$= \left(-\frac{c_1 D(S - S^0)^2}{S} - \frac{mS}{kH_2 + S} + c_2 D S \right) + \left( \frac{c_1 m}{A} + c_2 D \right) x$$

$$- \left( c_2 DS^0 - \frac{c_1 mS^0}{kA} - \frac{c_1 \sigma_1^2 S^0}{2} - D - \frac{1}{2} \sigma_2^2 \right),$$

$$\leq I(S) + \left( \frac{c_1 m}{A} + c_2 D \right) x - \eta,$$
where
\[
I(S) = -\frac{c_1 D (S - S^0)^2}{S} - \frac{mS}{kh_2 + S} + c_2 DS,
\]
\[
\eta = c_2 DS^0 - \frac{c_1 ms^0}{kA} - \frac{c_2}{2} \sigma_1^2 s_0^0 - D - \frac{1}{2} \sigma_2^2.
\]

Therefore, according to the previous function \(I(S)\), we have
\[
I'(S) = -\frac{c_1 D (S - S^0)^2}{S^2} - \frac{mkh_2}{(kh_2 + S)^2} + c_2 D,
\]
\[
I''(S) = -\frac{2c_1 D (S^0 - S^0)^2}{S^3} + \frac{2mkh_2}{(kh_2 + S)^3}.
\]

Obviously,
\[
I'(S)|_{S=S^0} = 0, \quad \text{for} \quad c_2 = \frac{mkh_2}{D (kh_2 + S^0)^2},
\]
\[
I''(S)|_{S=S^0} = -\frac{2c_1 D (kh_2 + S^0)^3}{S^0 (kh_2 + S^0)^3} < 0,
\]
for \(c_1 > \frac{mkh_2 S^0}{D (kh_2 + S^0)^3}\).

So,
\[
I(S) \leq I(S^0) = c_2 DS^0 - \frac{mS}{kh_2 + S^0} = -\frac{mS^0 (kh_2 + S^0)^2}{S^0 (kh_2 + S^0)^2} < 0,
\]
thus,
\[
LV_1 \leq -\eta + \left(\frac{c_1 m}{A} + c_2 D\right)x.
\]

Now, we estimate \(LV_2\) and \(LV_3\),
\[
dV_2 = (S + x)^\theta \left(\left(\frac{S^0}{S} - S\right)D - \frac{mSx}{(kx + S)(A + BS)} + \frac{mSx}{kx + S} - x D \right)dt
\]
\[
+ \theta (S + x)^{\theta - 1} (\sigma_1^2 S^2 + \sigma_2^2 x^2) dt + (S + x)^\theta (\sigma_1 S \sigma B_1 (t)) + \sigma_2 x B_2 (t))
\]
\[
= LV_2 dt + (S + x)^\theta (\sigma_1 S \sigma B_1 (t) + \sigma_2 x B_2 (t)).
\]

So,
\[
LV_2 = (S + x)^\theta \left(\left(\frac{S^0}{S} - S\right)D - \frac{mSx}{(kx + S)(A + BS)} + \frac{mSx}{kx + S} - x D \right)
\]
\[
+ \theta (S + x)^{\theta - 1} (\sigma_1^2 S^2 + \sigma_2^2 x^2),
\]
\[
\leq (S + x)^\theta S^0 D - (S + x)^{\theta + 1} D + mH_2 (S + x)^\theta
\]
\[
+ \theta (S + x)^{\theta - 1} (\sigma_1^2 S^2 + \sigma_2^2 x^2) (S + x)^2
\]
\[
= (S^0 D + mH_2) (S + x)^\theta - \left(\frac{D - \theta (\sigma_1^2 S^2 + \sigma_2^2 x^2)}{2} (S + x)^{\theta + 1},
\]
where the positive constant \(H_2\) is mentioned in Lemma 2.
\[
dV_3 = \frac{1}{S} \left(\frac{S^0 D - S D - \frac{mSx}{(kx + S)(A + BS)}}{S^0 D - S D - \frac{mSx}{(kx + S)(A + BS)}}\right) dt + \frac{1}{2} \sigma_1^2 dt
\]
\[
- \sigma_1 d B_1 (t)
\]
\[
= LV_3 dt - \sigma_1 d B_1 (t).
\]

So,
\[
LV_3 = -\frac{S^0 D}{S} + D + \frac{mSx}{(kx + S)(A + BS)} + \frac{1}{2} \sigma_1^2
\]
\[
\leq -\frac{S^0 D}{S} + D + \frac{m}{kA} + \frac{1}{2} \sigma_1^2,
\]
thus, from \(V(S, x) = NV_1 + V_2 + V_3 - H(S, x)\), we have
\[
LV \leq N \left(\eta + \left(\frac{c_1 m}{A} + c_2 D\right)D\right) + (S^0 D + mH_2) (S + x)^\theta
\]
\[
- \left(\frac{D - \theta (\sigma_1^2 S^2 + \sigma_2^2 x^2)}{2} (S + x)^{\theta + 1}
\]
\[
- \frac{S^0 D}{S} + D + \frac{m}{kA} + \frac{1}{2} \sigma_1^2
\]
\[
\equiv \psi_1 (S, x) + \psi_2 (x),
\]
where
through observation, we find that
\[ \psi_1(S,x) = (S^\theta D + mh_2)(S + x) - \left( D - \frac{\theta}{2} \left( \sigma_1^2 \vee \sigma_2^2 \right) \right) (S + x)^{\theta+1} - \frac{S^\theta D}{S} + D + \frac{m}{kA} + \frac{t^2}{2}, \quad (A.3) \]

Let \( U = (\varepsilon, (1/\varepsilon)) \times (\varepsilon, (1/\varepsilon)) \), where \( \varepsilon \) is a small enough constant. It follows that
\[ LV < 0, \quad (S, x) \in \mathbb{R}_+^2 \setminus U. \]

This implies that the model (4) admits a unique stationary distribution \( \mu(\cdot) \).
Thus, the proof is completed. \( \square \)

**Remark 5.** By Theorem 4, we know that the model (4) has a unique stationary distribution if the condition holds, which means that the microorganism is persistent in the future.

### 4. Stochastic Maximum Principle

In this section, the existence of the optimal stochastic control for the model (4) is proved. Our aim is to find an optimal stochastic control under given the initial conditions such that the production of the microorganism is maximized at a given time \( T \). We select the dilution rate \( D \) as stochastic control variable \( D(t) \). Several preliminaries are given.

For convenience, the model (4) can be rewritten as
\[
\begin{align*}
    dS(t) &= f_1(S(t), x(t), D(t))dt + \sigma_1 S(t)dB_1(t), \quad (S(0), x(0)) \in \mathcal{F}_0 \times \mathbb{R}, \\
    dx(t) &= f_2(S(t), x(t), D(t))dt + \sigma_2 x(t)dB_2(t),
\end{align*}
\]  

where
\[
\begin{align*}
    f_1(S(t), x(t), D(t)) &= \left( S^\theta - S(t) \right) D(t) - \frac{mS(t)}{kx(t) + S(t)} x(t) \left( \frac{1}{A + BS(t)} \right), \\
    f_2(S(t), x(t), D(t)) &= x(t) \left( \frac{mS(t)}{kx(t) + S(t)} - D(t) \right).
\end{align*}
\]  

The stochastic control variable \( D(t) \) is a non-negative continuous bounded function. Let the constant \( V \) denote the volume of the culture vessel, and let \( F(t) \) be the volumetric flow rate, then the dilution rate \( D(t) = (F(t)/V) \). For convenience, we define \( V = 1 \), so \( D(t) = F(t) \), the production function is expressed as

\[ M(t) = \int_0^t \mathcal{M}(t)dt, \quad (90) \]

where \( \mathcal{M}(t) = x(t)F(t) - x(t)D(t) \) is a continuous function denoting the production of unit time of the microorganism. Since we will focus on the maximum microorganism production problem in the interval \([0, T]\), the objective functional is given as
\[ J(D(\cdot)) = \mathbb{E}[M(T)] = \mathbb{E}\left\{ \int_0^T x(t)D(t)dt \right\}. \]

Denote a bounded nonempty closed set \( \mathcal{A} \subset \mathbb{R} \), and the set of admissible controls is defined as follows:
\[ \mathcal{A}_{ad} = \{ D : [0, T] \times \Omega \to \mathcal{A} | D \text{ is } [\mathcal{F}_t]_{t \geq 0} \text{ adapted} \}. \]

For any \( D \in \mathcal{A}_{ad} \), equation (87) is a stochastic differential equation with random coefficients, which has a unique strong solution \( (S(t), x(t)) \) called an admissible state trajectory, and \( (S(t), x(t), D(t)) \) is called an admissible triple.

The objective functional (90) can be rewritten as
\[ J(D(\cdot)) = \mathbb{E}\left\{ \int_0^T L(S(t), x(t), D(t))dt \right\}, \quad (92) \]

where
\[ L(S(t), x(t), D(t)) = x(t)D(t), \quad (93) \]

and
\[ J(\bar{D}) = \sup_{D \in \mathcal{A}_{ad}} J(D), \quad (94) \]

where \( \bar{D} \) is called an optimal stochastic control. \((\bar{S}, \bar{x})\) is called the corresponding solution of the model (87) and \((\bar{S}, \bar{x}, \bar{D})\) is called an optimal triple.

Define a Hamiltonian function \( H : \mathbb{R}_+ \times \mathbb{R}_+ \times \mathcal{A} \times \mathbb{R} \times \mathbb{R} \times \mathbb{R} \to \mathbb{R} \) by
\[
H(S(t), x(t), D(t), p_1(t), p_2(t), q_1(t), q_2(t)) = f_1(S(t), x(t), D(t))p_1(t) + f_2(S(t), x(t), D(t))p_2(t) + \sigma_1 S(t)q_1(t) + \sigma_2 x(t)q_2(t) + L(S(t), x(t), D(t)).
\]

The adjoint equation corresponding to the admissible triple \((S(t), x(t), D(t))\) on the unknown \([\mathcal{F}_t]_{t \geq 0}\)-adapted processes \((p_1(t), p_2(t), q_1(t), q_2(t))\) is the backward stochastic differential equation with the natural boundary conditions:
\[
\begin{cases}
    \frac{dp_1}{dt} = -g_1(S(t), x(t), D(t), p_1(t), p_2(t), q_1(t), q_2(t))dt + q_1(t)dB_1(t), \\
    \frac{dp_2}{dt} = -g_2(S(t), x(t), D(t), p_1(t), p_2(t), q_1(t), q_2(t))dt + q_2(t)dB_2(t), \\
    p_1(T) = 0, \\
    p_2(T) = 0,
\end{cases}
\]

where

\[g_1(S, x, D, p_1, p_2, q_1, q_2) = -\left(D + \frac{1}{(kx + S)^2}(A + BS)^2\right)p_1 + \frac{mx(Akx - BS)}{(kx + S)^2} \quad \text{and} \quad g_2(S, x, D, p_1, p_2, q_1, q_2) = -\frac{mS^2}{(kx + S)^2}(A + BS)^2p_1 + \left(\frac{mS^2}{(kx + S)^2} - D\right)p_2 + \sigma_2 q_2 + D.\]

Next, the necessary condition of the optimal stochastic control for the model (4) is established.

**Theorem 5.** Suppose that there exists an adapted solution \((\bar{p}_1, \bar{p}_2, \bar{q}_1, \bar{q}_2)\) of the corresponding adjoint equation (95) such that for all \(D \in \mathcal{A}_{a.d.}\), we have

\[
\mathbb{E}\left\{\int_0^T \left[ (\bar{S} - S)^2 \bar{q}_1^2 + (\bar{x} - x)^2 \bar{q}_2^2 \right] dt \right\} < \infty, \tag{97}
\]

and

\[
\mathbb{E}\left\{\int_0^T \left[ \sigma_1^2 \bar{p}_1^2 + \sigma_2^2 x^2 \bar{p}_2^2 \right] dt \right\} < \infty. \tag{98}
\]

Furthermore, if the following conditions hold,

(i) The Hamiltonian \(H(S, x, D, \bar{p}_1, \bar{p}_2, \bar{q}_1, \bar{q}_2)\) with respect to \((S, x, D)\) is concave for all \(t \in [0, T]\)

(ii) \(H(\bar{S}, \bar{x}, \bar{D}, \bar{p}_1, \bar{p}_2, \bar{q}_1, \bar{q}_2) = \max_{\{D \in \mathcal{A}_{a.d.}\}} H(\bar{S}, \bar{x}, \bar{D}, \bar{p}_1, \bar{p}_2, \bar{q}_1, \bar{q}_2)\), for all \(t \in [0, T]\)

then, \((\bar{S}, \bar{x}, \bar{D})\) is an optimal triple and \(\bar{D}\) is an optimal stochastic control.

**Proof.** Proof. For any control triple \((S, x, D) \in \mathcal{A}_{a.d.}\), we consider

\[
J(\bar{D}) - J(D) = \mathbb{E}\left\{\int_0^T L(\bar{S}, \bar{x}, \bar{D}) dt \right\} - \mathbb{E}\left\{\int_0^T L(S, x, D) dt \right\} \\
= \mathbb{E}\left\{\int_0^T \left[ L(\bar{S}, \bar{x}, \bar{D}) - L(S, x, D) \right] dt \right\} \pm 1.
\]

(99)

By the Hamiltonian function \(H\) and the assumption of \((\bar{p}_1, \bar{p}_2, \bar{q}_1, \bar{q}_2)\), we have

\[
L(S, x, D) = H(S, x, D, \bar{p}_1, \bar{p}_2, \bar{q}_1, \bar{q}_2) - f_1(S, x, D) \bar{p}_1 - f_2(S, x, D) \bar{p}_2 - \sigma_1 \bar{S} \bar{q}_1 - \sigma_2 x \bar{q}_2,
\]

therefore

\[
I = \mathbb{E}\left\{\int_0^T [H(\bar{S}, \bar{x}, \bar{D}, \bar{p}_1, \bar{p}_2, \bar{q}_1, \bar{q}_2) - H(S, x, D, \bar{p}_1, \bar{p}_2, \bar{q}_1, \bar{q}_2)] dt \right\} \\
= \mathbb{E}\left\{\int_0^T \left[ f_1(\bar{S}, \bar{x}, \bar{D}) \bar{p}_1 - f(S, x, D) \bar{p}_1 \right] dt \right\} - \mathbb{E}\left\{\int_0^T \left[ f_2(\bar{S}, \bar{x}, \bar{D}) \bar{p}_2 - f(S, x, D) \bar{p}_2 \right] dt \right\} \\
= \mathbb{E}\left\{\int_0^T \left[ \sigma_1 \bar{S} \bar{q}_1 - \sigma_1 \bar{S} \bar{q}_1 \right] dt \right\} - \mathbb{E}\left\{\int_0^T \left[ \sigma_2 x \bar{q}_2 - \sigma_2 x \bar{q}_2 \right] dt \right\}.
\]

(101)

Since the concavity of \(H\) in \(S, x\) and \(D\), we get

\[
I \geq \mathbb{E}\left\{\int_0^T \left[ (\bar{S} - S)H_S(\bar{S}, \bar{x}, \bar{D}, \bar{p}_1, \bar{p}_2, \bar{q}_1, \bar{q}_2) + (\bar{x} - x)H_x(\bar{S}, \bar{x}, \bar{D}, \bar{p}_1, \bar{p}_2, \bar{q}_1, \bar{q}_2) \right] dt \right\} \\
+ \mathbb{E}\left\{\int_0^T \left[ (\bar{D} - D)H_D(\bar{S}, \bar{x}, \bar{D}, \bar{p}_1, \bar{p}_2, \bar{q}_1, \bar{q}_2) \right] dt \right\} - \mathbb{E}\left\{\int_0^T \left[ f_1(\bar{S}, \bar{x}, \bar{D}) \bar{p}_1 - f_1(S, x, D) \bar{p}_1 \right] dt \right\} \\
- \mathbb{E}\left\{\int_0^T \left[ f_2(\bar{S}, \bar{x}, \bar{D}) \bar{p}_2 - f_2(S, x, D) \bar{p}_2 \right] dt \right\} - \mathbb{E}\left\{\int_0^T \left[ \sigma_1 \bar{S} \bar{q}_1 - \sigma_1 \bar{S} \bar{q}_1 \right] dt \right\} \\
- \mathbb{E}\left\{\int_0^T \left[ \sigma_2 x \bar{q}_2 - \sigma_2 x \bar{q}_2 \right] dt \right\} \pm I_1 + I_2.
\]

(102)
where

\[
I_1 = \mathbb{E}\left\{ \int_0^T \left[ (\mathcal{S} - S)\mathcal{H}_S(\mathcal{S}, \mathcal{\bar{x}}, \mathcal{\bar{D}}, \mathcal{\bar{p}}_1, \mathcal{\bar{p}}_2, \mathcal{\bar{q}}_1, \mathcal{\bar{q}}_2) + (\mathcal{\bar{x}} - x)\mathcal{H}_x(\mathcal{S}, \mathcal{\bar{x}}, \mathcal{\bar{D}}, \mathcal{\bar{p}}_1, \mathcal{\bar{p}}_2, \mathcal{\bar{q}}_1, \mathcal{\bar{q}}_2) \right] d\mathcal{t} \right\}
\]

\[
- \mathbb{E}\left\{ \int_0^T \left[ f_1(\mathcal{S}, \mathcal{\bar{x}}, \mathcal{\bar{D}})\mathcal{\bar{p}}_1 - f_1(S, x, D)\mathcal{p}_1 \right] d\mathcal{t} \right\} - \mathbb{E}\left\{ \int_0^T \left[ f_2(\mathcal{S}, \mathcal{\bar{x}}, \mathcal{\bar{D}})\mathcal{\bar{p}}_2 - f_2(S, x, D)\mathcal{p}_2 \right] d\mathcal{t} \right\}
\]

\[
- \mathbb{E}\left\{ \int_0^T \left[ \sigma_1 \mathcal{\bar{q}}_1 - \sigma_1 \mathcal{q}_1 \right] d\mathcal{t} \right\} - \mathbb{E}\left\{ \int_0^T \left[ \sigma_2 \mathcal{\bar{q}}_2 - \sigma_2 \mathcal{q}_2 \right] d\mathcal{t} \right\},
\]

\[
I_2 = \mathbb{E}\left\{ \int_0^T \left[ (\mathcal{\bar{D}} - D)\mathcal{H}_D(\mathcal{S}, \mathcal{\bar{x}}, \mathcal{\bar{D}}, \mathcal{\bar{p}}_1, \mathcal{\bar{p}}_2, \mathcal{\bar{q}}_1, \mathcal{\bar{q}}_2) \right] d\mathcal{t} \right\}.
\]

Conditions (97) and (98) ensure that the stochastic integrals have zero mean. Next, we will estimate \( I_1 \) by Itô product formula and the natural boundary conditions of (95).

\[
I_1 = \mathbb{E}\left\{ \int_0^T \left[ (\mathcal{S} - S)\mathcal{H}_S(\mathcal{S}, \mathcal{\bar{x}}, \mathcal{\bar{D}}, \mathcal{\bar{p}}_1, \mathcal{\bar{p}}_2, \mathcal{\bar{q}}_1, \mathcal{\bar{q}}_2) - (f_1(\mathcal{S}, \mathcal{\bar{x}}, \mathcal{\bar{D}}) - f_1(S, x, D))\mathcal{\bar{p}}_1 - (\mathcal{\bar{S}} - S)\sigma_1 \mathcal{\bar{q}}_1 \right] d\mathcal{t} \right\}
\]

\[
+ \mathbb{E}\left\{ \int_0^T \left[ (\mathcal{\bar{x}} - x)\mathcal{H}_x(\mathcal{S}, \mathcal{\bar{x}}, \mathcal{\bar{D}}, \mathcal{\bar{p}}_1, \mathcal{\bar{p}}_2, \mathcal{\bar{q}}_1, \mathcal{\bar{q}}_2) - (f_2(\mathcal{S}, \mathcal{\bar{x}}, \mathcal{\bar{D}}) - f_2(S, x, D))\mathcal{\bar{p}}_2 - (\mathcal{\bar{x}} - x)\sigma_2 \mathcal{\bar{q}}_2 \right] d\mathcal{t} \right\}
\]

\[
= -\mathbb{E}\left\{ \int_0^T (\mathcal{S} - S) d\mathcal{\bar{p}}_1 + \int_0^T \mathcal{\bar{p}}_1 d(\mathcal{S} - S) + \int_0^T d\mathcal{\bar{p}}_1 d(\mathcal{S} - S) \right\}
\]

\[
- \mathbb{E}\left\{ \int_0^T (\mathcal{\bar{x}} - x) d\mathcal{\bar{p}}_2 + \int_0^T \mathcal{\bar{p}}_2 d(\mathcal{\bar{x}} - x) + \int_0^T d\mathcal{\bar{p}}_2 d(\mathcal{\bar{x}} - x) \right\}
\]

\[
= -\mathbb{E}\{\mathcal{\bar{S}}(T) - S(T)\mathcal{\bar{p}}_1(T)\} - \mathbb{E}\{\mathcal{\bar{x}}(T) - x(T)\mathcal{\bar{p}}_2(T)\}
\]

\[
= 0.
\]

Applying the condition (ii) of theorem,

\[
\mathbb{E}\{ (\mathcal{\bar{D}}(t) - D(t))\mathcal{H}_D(\mathcal{\bar{S}}, \mathcal{\bar{x}}, \mathcal{\bar{D}}, \mathcal{\bar{p}}_1, \mathcal{\bar{p}}_2, \mathcal{\bar{q}}_1, \mathcal{\bar{q}}_2) \}
\]

\[
= (\mathcal{\bar{D}}(t) - D(t))\mathbb{E}\{ \mathcal{H}_D(\mathcal{\bar{S}}, \mathcal{\bar{x}}, \mathcal{\bar{D}}, \mathcal{\bar{p}}_1, \mathcal{\bar{p}}_2, \mathcal{\bar{q}}_1, \mathcal{\bar{q}}_2) \}|_{\mathcal{\bar{D}} = D} \geq 0,
\]

(105)

then

\[
I_2 = \mathbb{E}\left\{ \int_0^T \left[ (\mathcal{\bar{D}} - D)\mathcal{H}_D(\mathcal{\bar{S}}, \mathcal{\bar{x}}, \mathcal{\bar{D}}, \mathcal{\bar{p}}_1, \mathcal{\bar{p}}_2, \mathcal{\bar{q}}_1, \mathcal{\bar{q}}_2) \right] d\mathcal{t} \right\} \geq 0.
\]

(106)

Hence, we have \( I = I_1 + I_2 \geq 0 \); that is,

\[
J'(\mathcal{\bar{D}}) \geq J(D).
\]

(107)

Considering \((S, x, D)\) is arbitrary, then \((\mathcal{\bar{S}}, \mathcal{\bar{x}}, \mathcal{\bar{D}})\) is an optimal triple and \(\mathcal{\bar{D}}\) is an optimal stochastic control. This completes the proof of Theorem 5.

Since the control variable \( D \) appears linearly in the Hamiltonian function \( H(S, x, D, p_1, p_2, q_1, q_2) \). This indicates that the problem may have an optimal stochastic singular control. However, it is usually difficult to find the exact optimal stochastic singular control. To this end, we will introduce a small perturbation to turn the singular control into a nonsingular control and call it a near-optimal stochastic control of this problem.

Let the objective functional is

\[
J'(D(t)) = \mathbb{E}\left\{ \int_0^T \left( (x(t)D(t) - 1/2\varepsilon D(t))^2 \right) d\mathcal{t} \right\}.
\]

(108)

where \((1/2)\varepsilon D(t)^2\) represents a small perturbation, and the positive constant \(\varepsilon\) is small enough to ensure \(x(t)D(t) - (1/2)\varepsilon D(t)^2 > 0\). Thus, the Hamiltonian function can be rewritten as

\[
H'(S(t), x(t), D(t), p_1(t), p_2(t), q_1(t), q_2(t))
\]

\[
= f_1(S(t), x(t), D(t))p_1(t) + f_2(S(t), x(t), D(t))p_2(t)
\]

\[
+ \sigma_1 S(t) q_1(t) + \sigma_2 x(t) q_2(t) + x(t) D(t) - \frac{1}{2} \varepsilon D(t)^2.
\]

(109)

The necessary conditions for the near-optimal stochastic control are \(H'_D = 0\) and \(H'_{D'D} < 0\) at the point \((\mathcal{\bar{S}}, \mathcal{\bar{x}}, \mathcal{\bar{D}}, \mathcal{\bar{p}}_1, \mathcal{\bar{p}}_2, \mathcal{\bar{q}}_1, \mathcal{\bar{q}}_2)\). Hence, we get the following result. □
Corollary 1. The model (4) has a near-optimal stochastic control:
\[
\tilde{D} = \frac{1}{k} \left( (S^0 - S) \tilde{p}_1 - \tilde{x} \tilde{p}_2 + \tilde{x} \right),
\]
and the corresponding optimal triple \((\tilde{S}, \tilde{x}, \tilde{D})\).

\[
\begin{align*}
S_{i+1} &= S_i + \left( (S^0 - S) D - \frac{mS_i}{kx_i + S_i} \frac{S_i}{A + BS_i} \right) \Delta t + S_i \left( \sigma_1 \xi_1 \sqrt{\Delta t} + \frac{\sigma_1^2}{2} (\xi_1^2 - 1) \Delta t \right), \\
x_{i+1} &= x_i + x_i \left( \frac{mS_i}{kx_i + S_i} - D \right) \Delta t + x_i \left( \sigma_2 \xi_2 \sqrt{\Delta t} + \frac{\sigma_2^2}{2} (\xi_2^2 - 1) \Delta t \right).
\end{align*}
\]

where \(\xi_i, \xi_i \), \(i = 1, 2, \ldots\) are independent \(\mathcal{N}(0, 1)\)-distributed Gaussian random variables.

Next, we present numerical simulations to demonstrate our theoretical results of the model (4) by Milstein method [33]. The discretized equations are listed as follows:

\[
\frac{1}{2} \sigma_2^2 < \frac{m}{kH_2 + 1} - D < \frac{mS_0}{kH_2 + 1} - D,
\]

which means that when the condition of Theorem 3 satisfies, then the microorganism is almost surely strongly persistent in the mean (see Figure 3).

Example 4. For the model (3) and (4), choose two sets of parameters:

\[
S^0 = 0.9, m = 1.4, k = 1, D = 0.1, H_2 = 10, A = 2, B = 0, \\
\sigma_1 = 0.15, \sigma_2 = 0.15, Figures 4(a) and 4(b)
\]

and

\[
S^0 = 0.9, m = 1.4, k = 1, D = 0.1, H_2 = 10, A = 2, B = 3, \\
\sigma_1 = 0.15, \sigma_2 = 0.15, Figures 4(c) and 4(d)
\]

and the initial point is \((S_0, x_0) = (0.4, 0.5)\). Since

\[
\frac{1}{2} \sigma_2^2 \simeq 0.0113, \\
\frac{m}{kH_2 + 1} - D \simeq 0.0145,
\]

which means that when the condition of Theorem 3 satisfies, then the microorganism is almost surely strongly persistent in the mean (see Figure 3).

5. Numerical Simulations

Numerical simulations are presented for supporting our theoretical results of the model (4) by Milstein method [33]. The discretized equations are listed as follows:

\[
\frac{1}{2} \sigma_2^2 < \frac{m}{kH_2 + 1} - D < \frac{mS_0}{kH_2 + 1} - D,
\]

which means that when the condition of Theorem 3 satisfies, then the microorganism is almost surely strongly persistent in the mean (see Figure 3).
obviously,
\[ \frac{1}{2} < \frac{m s_0}{k H_2 + 1} - D < \frac{m}{k H_2 + 1} - D, \]  
which means that when the condition of Theorem 3 satisfies, then the microorganism is almost surely strongly persistent in the mean (see Figure 4).

Through the above numerical simulations, we know that the parameters \( B \) rarely affect the extinction of the microorganism \( x(t) \) and have a significant impact on the persistence of the microorganism \( x(t) \), that is, the concentration of the microorganism \( x(t) \) increases with the parameter \( B \) (see Figures 3(b), 3(d), 4(b), and 4(d)). In conclusion, the intensities of white noise are disadvantageous to the growth of the microorganism, and the variable yield \( y(S) = A + BS \) is advantageous to the growth of the microorganism.

Data Availability

The “simulation” data used to support the findings of this study are included within the article. These data are not obtained by experiments; just to satisfy the conditions of the theorem, we design them artificially.

Conflicts of Interest

The authors declare that they have no conflicts of interest.
