(Dated: February 1, 2008)

Using a generalized model of interaction between a two-level system (TLS) and an arbitrary deformation of the material, we calculate the interaction of Lamb modes with TLSs in amorphous nanoscopic membranes. We compare the mean free paths of the Lamb modes with different symmetries and calculate the heat conductivity $\kappa$. In the limit of an infinitely wide membrane, the heat conductivity is divergent. Nevertheless, the finite size of the membrane imposes a lower cut-off for the phonons frequencies, which leads to the temperature dependence $\kappa \propto T(a + b \ln T)$. This temperature dependence is a hallmark of the TLS-limited heat conductance at low temperature.

PACS numbers:

I. INTRODUCTION

The development of nanodetectors and the strict requirements on their performance triggered intense experimental and theoretical studies of their thermal properties. These detectors work usually in a temperature range around 1 K or below and are supported by thin, insulating membranes. The thickness of such membranes is of the order of 100 nm, which, in the given temperature range, makes it comparable to the dominant thermal phonon wavelength. In problems where the phonon wavelength is comparable to or longer than some of the dimensions of the system in question, the three dimensional (3D) phonon gas model cannot be applied anymore to calculate the system’s thermal properties. Instead, one has to use the phonon modes specific to the system, which are the eigenmodes of the elastic equation for the given geometry.

The membranes that support the detectors are made of amorphous, low stress silicon-nitride (SiN$_x$) and their thermal properties have been measured in various geometries by different groups (see for example Refs. 1, 2, 3, 4). Depending on the quality and the dimensions of the samples, and possibly the temperature range in which measurements were done, the heat flux along the membrane may be due to either diffusive or radiative phonon transport. In the case of diffusive phonon transport, it was observed that the heat conductivity $\kappa$ is roughly proportional to $T^2$.

For a better thermal insulation of the detector, the underlying membrane is sometimes cut. The result is a self-supporting structure with a wider area in the middle, connected to the bulk by long, narrow bridges, like in Fig. 1. The heat conductivity along such bridges has again a power law dependence on the temperature, $\kappa \propto T^p$, where $p$ takes values between 1.5 and 2. For the samples measured in 2, $p$ increased with the width of the bridge.

The heat capacity of a membrane is more difficult to measure directly, since the membrane is always in contact with the bulk. However, it can be estimated by applying AC heating and measuring the amplitude of the temperature oscillations. In this way Leivo and Pekola observed that the ratio $c_V/\kappa$, where $c_V$ is the heat capacity, increases with temperature for the narrowest bridges.

As mentioned above, to explain theoretically all these observations we have to work with the proper set of phonon modes. For wide membranes with parallel surfaces, the eigenmodes of the elastic equations are called Lamb modes and horizontal shear modes, as explained for example in Ref. 8. Using these modes and their dispersion relations, we could describe quite well the thermal properties of the membranes in the low temperature limit, i.e. at temperatures where the characteristic thermal wavelength of the phonons is much longer than the thickness of the membrane.

Nevertheless, the same temperature dependence of the heat conductivity and heat capacity persists also in a temperature range where this characteristic ther-
We can rewrite the function $t$ tunnel splitting of a matrix.

The TLSs that have an excitation energy comparable to $k_B T$ are very efficient phonon scatterers.

The deformation due to the displacement field of a phonon is qualitatively described by the strain field, which will be represented here by the 6-component vector $S$. If we denote the displacement field by $u(r)$, then the strain is defined as the symmetric gradient of $u(r)$, i.e.

$$S^T \equiv (\nabla_S u)^T = (\partial_x u_x, \partial_y u_y, \partial_z u_z + \partial_x u_y + \partial_y u_z, \partial_x u_z, \partial_y u_x + \partial_y u_z, \partial_z u_x + \partial_y u_y + \partial_z u_z).$$

This deformation adds a time-dependent perturbation to the Hamiltonian, which we shall denote by $H_1$. The perturbation is assumed to be diagonal, when written in the basis of the two ground states of the potential wells (like in Eq. (1))

$$H_1 = \delta \sigma_z,$$

and linear in the strain field at the location of the TLSs.

$$\delta = 2 \tilde{\gamma} T^f \cdot [r] \cdot S .$$

The other quantities in Eq. (5) are the coupling constant $\tilde{\gamma}$, the six component vector $T$, which is defined by a generic orientation $\hat{t}$ of the TLS as $T \equiv (t_x, t_y, t_z, t_{xz}, t_{xz}, t_{yz})^T$, and the 6 $\times$ 6 matrix of the deformation potential parameters $[r]$. For isotropic materials, the matrix $[r]$ is

$$[r] = \begin{pmatrix} 1 & \zeta & 0 & 0 & 0 \\ \zeta & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \xi \\ 0 & 0 & 0 & \xi & 0 \end{pmatrix},$$

with the TLS potential parameters $\zeta$ and $\xi$ that satisfy the condition $\zeta + 2 \xi = 1$.

To calculate the scattering probabilities we have to write $H_1$ in the second quantization. For this we denote the TLS excited state by $|\uparrow\rangle$ and its ground state by $|\downarrow\rangle$ and we introduce the “creation” and “annihilation” operators $a^\dagger$ and $a$, respectively, so that $a^\dagger |\downarrow\rangle = |\uparrow\rangle$, $a |\uparrow\rangle = |\downarrow\rangle$, $a^\dagger |\uparrow\rangle = 0$, and $a |\downarrow\rangle = 0$. The operators $a$ and $a^\dagger$ obey Fermi commutation relations and in matrix form we have $\sigma_z = (2a^\dagger a - 1)$ and $\sigma_x = (a^\dagger + a)$. The bosonic creation and annihilation operators for phonons will be denoted by $b^\dagger_{\mu}$ and $b_{\mu}$, respectively, where $\mu$ stands in general for the quantum numbers of the phonon modes (see for example Refs. [11,14]). Using these notations and applying the transformation $O$ to the total Hamiltonian $(O^T (H_{TLS} + H_1) O) \equiv H'_{TLS} + H'_1$, we obtain

$$H'_1 = \frac{\tilde{\gamma} \Lambda}{\epsilon} T^T \cdot [r] \cdot \sum_{\mu} \left[ S^\mu b_{\mu} + S^\dagger_{\mu} b^\dagger_{\mu} \right] (2a^\dagger a - 1) - \frac{\tilde{\gamma} \Lambda}{\epsilon} T^T \cdot [r] \cdot \sum_{\mu} \left[ S^\mu b_{\mu} + S^\dagger_{\mu} b^\dagger_{\mu} \right] (a^\dagger + a).$$

In the first order perturbation theory, the phonon absorption and emission rates are determined by the off-diagonal elements of $H'_1$, i.e. of the second row of Eq. (7). Higher order processes are not considered here.
A. The phonon modes in the membrane

The phonon modes of a free standing, infinite membrane are divided into three groups, according to their symmetry properties. One group is formed of simple, transversally polarized modes, called the horizontal shear modes (h). The two other groups are the symmetric (s) and antisymmetric (a) Lamb modes. Together, these modes form a complete, orthonormal set of functions for the elastic displacement fields in the membrane and their proper quantization has been carried out in Ref. [16]. In this paper we shall use the results and notations from there and we shall call the three different types of phonons (i.e. h, s and a) polarizations.

We assume that the membrane of thickness d is placed parallel to the (xy) plane and its parallel surfaces cut the z axis at ±d/2. The phonons propagate in the (xy) plane with the wave vector \( \mathbf{k}_h = k_h \hat{\mathbf{z}}, \) of real \( k_h \). We use hat to denote unit vectors.

Along the z direction, the phonon modes are stationary. As the h modes are pure transversal waves, they have only one wave vector component along the z direction, which we denote by \( k_h \). The s and a waves are superpositions of transversal and longitudinal waves of wave vector components along the z direction denoted by \( k_t \) and \( k_l \) respectively. Due to the boundary conditions, which demand that the membrane surfaces are stress-free, \( k_h \) takes the discrete values \( m \pi / d \), with \( m \) taking all integer values between 0 and \( \infty \), whereas \( k_t \) and \( k_l \) satisfy the more complicated relations:

\[
\tan(k_t d/2) = -\frac{4k_tk_lk_s^2}{(k_t^2 - k_s^2)^2}, \tag{8a}
\]

for the symmetric modes and

\[
\tan(k_l d/2) = -\frac{4k_tk_lk_s^2}{(k_t^2 - k_s^2)^2}, \tag{8b}
\]

for the antisymmetric modes. Equations (8) plus Snell’s law, \( \omega^2 = c_s^2(k_t^2 + k_s^2) = c_t^2(k_t^2 + k_s^2) \), enable us to write \( k_t \) as a function of \( k_l \) for each of the polarizations \( s \) and \( a \). (In Snell’s law, \( c_t \) and \( c_s \) are the respective transversal and longitudinal sound velocities for bulk media.) Like in the case of the \( h \) modes, the dispersion relations for the symmetric and antisymmetric modes split into branches, i.e. Eqs. (8) and Snell’s law do not give only one function \( k_t(k_l) \) for either set of modes, but produce an infinite, countable set of such functions. These functions will be called phonon branches and we shall number them with \( m = 0, 1, \ldots \), as we did in Ref. [16], where branches of bigger \( m \) lie above branches of smaller \( m \).

A simple way to express the quantum numbers of the phonon modes is to use Eqs. (8) and Snell’s law to write the functions \( k_t(k||) \) and \( k_l(k||) \). Then each branch, of polarization \( \sigma = s, a \) and branch number \( m \), is going to be described by the continuous set of numbers \( \{k_t(k||), k_l(k||)\}_{\sigma, m} \), with \( k|| \) taking values from 0 to \( \infty \). We therefore choose the set \( \mu \) of quantum numbers that specify the phonon modes in Eq. (7) to be \( \mu \equiv \{\sigma, m, k||\} \).

The functions \( k_t(k||) \) and \( k_l(k||) \) may take both, real and imaginary values. To distinguish between these situations, we write the imaginary values of \( k_t \) as \( ik_t \) and the imaginary values of \( k_l \) as \( ik_l \). In these notations, \( k_t \) and \( k_l \) take always positive, real values.

In order to simplify the later discussion, we shall replace \( k_t \) and \( k_l \) with the complex quantities \( \tilde{k}_t \equiv k_t + ik_t \) and \( k_l \equiv k_l + ik_l \), respectively. Note, however, that \( \tilde{k}_t \) and \( k_l \) are never really complex, but they are either real or imaginary, as long as \( k|| \) is real.\[16\]

The displacement fields of the phonon modes are\[8,16\]

\[
\mathbf{u}_h = N_h \cos(k_h(z-d/2)) (\mathbf{k}_|| \times \hat{\mathbf{z}}) e^{i(k|| \cdot \mathbf{r} - \omega t)} \tag{9a}
\]

\[
\mathbf{u}_s = N_s \left\{ i\tilde{k}_t \left( 2k|| \cos(\tilde{k}_t d/2) \cos(\tilde{k}_l z) + [k_l^2 - k||^2] \cos(\tilde{k}_l d/2) \cos(\tilde{k}_l z) \right) \hat{\mathbf{k}}_|| 
- k_l \left( 2\tilde{k}_t k_l \cos(\tilde{k}_l d/2) \sin(\tilde{k}_l z) - [k_l^2 - k||^2] \cos(\tilde{k}_l d/2) \sin(\tilde{k}_l z) \right) \hat{\mathbf{z}} \right\} e^{i(k|| \cdot \mathbf{r} - \omega t)} \tag{9b}
\]

\[
\mathbf{u}_a = N_a \left\{ i\tilde{k}_l \left( 2k|| \sin(\tilde{k}_l d/2) \sin(\tilde{k}_l z) + [k_l^2 - k||^2] \sin(\tilde{k}_l d/2) \sin(\tilde{k}_l z) \right) \hat{\mathbf{k}}_|| 
+ k_l \left( 2\tilde{k}_t k_l \sin(\tilde{k}_l d/2) \cos(\tilde{k}_l z) - [k_l^2 - k||^2] \sin(\tilde{k}_l d/2) \cos(\tilde{k}_l z) \right) \hat{\mathbf{z}} \right\} e^{i(k|| \cdot \mathbf{r} - \omega t)}. \tag{9c}
\]

As one can see, when \( \tilde{k}_t \) or \( \tilde{k}_l \) take imaginary values, the trigonometric functions in (9) will switch into hyperbolic functions. The normalization constants \( N_h, N_s \) and \( N_a \) are given by\[16\].
\[ N_m^2 = \begin{cases} V/m = 0 \\ V/2/m > 0 \end{cases} \] (10a)

\[ N_s^2 = A \left\{ 4|\bar{k}_t|^2 k_t^2 \cos(\bar{k}_t d/2)|^2 \left( (|\bar{k}_t|^2 + k_t^2) \sinh(\kappa_t d) / 2\kappa_t - (|\bar{k}_t|^2 - k_t^2) \sin(\kappa_t d) / 2k_t \right) \right. \\
+ \left. (|\bar{k}_t|^2 - k_t^2)|^2 \left( (|\bar{k}_t|^2 + k_t^2) \sinh(\kappa_t d) / 2\kappa_t + (|\bar{k}_t|^2 - k_t^2) \sin(\kappa_t d) / 2k_t \right) \right. \\
- \left. 4k_t^2 \cos(\kappa_t d/2)|^2 \left( \kappa_t (|\bar{k}_t|^2 + k_t^2) \sinh(\kappa_t d) - k_t (|\bar{k}_t|^2 - k_t^2) \sin(\kappa_t d) \right) \right\} \] (10b)

\[ N_a^2 = A \left\{ 4|\bar{k}_t|^2 k_t^2 |\sin(\kappa_t d/2)|^2 \left( (|\bar{k}_t|^2 + k_t^2) \sinh(\kappa_t d) / 2\kappa_t + (|\bar{k}_t|^2 - k_t^2) \sin(\kappa_t d) / 2k_t \right) \right. \\
+ \left. (|\bar{k}_t|^2 - k_t^2)|^2 \left( (|\bar{k}_t|^2 + k_t^2) \sinh(\kappa_t d) / 2\kappa_t - (|\bar{k}_t|^2 - k_t^2) \sin(\kappa_t d) / 2k_t \right) \right. \\
- \left. 4k_t^2 |\sin(\kappa_t d/2)|^2 \left( \kappa_t (|\bar{k}_t|^2 + k_t^2) \sinh(\kappa_t d) + k_t (|\bar{k}_t|^2 - k_t^2) \sin(\kappa_t d) \right) \right\} , \] (10c)

where \( A \) is the area of the membrane and \( V = d \cdot A \) is the volume. To obtain the expressions for \( N_s \) and \( N_a \) for the different combinations of real or imaginary \( \bar{k}_t \) and \( k_t \), one has to take the limit to 0 of their redundant components in (10b) and (10c). For example if \( \bar{k}_t \) is real and \( k_t \) is imaginary, we calculate the corresponding normalization factor by taking in Eq. (10b) or (10c) the limits \( \kappa_t \to 0 \) and \( k_t \to 0 \).

III. TRANSITION RATES

Now we have all the ingredients to calculate TLS transition rates or phonon absorption and emission probabilities. We shall denote the phonon-TLS quantum states by \( |n_{\mu}, \downarrow \rangle \) or \( |n_{\mu}, \uparrow \rangle \), where we denoted the number of phonons on the mode \( \mu \) by \( n_{\mu} \). Using Eq. (7) we write the emission amplitude of a phonon by a TLS as

\[ \langle n_{\mu}, \uparrow | \hat{H}_I | n_{\mu} + 1, \downarrow \rangle = -\frac{\gamma_{\Lambda}}{\epsilon} \sqrt{\frac{\hbar n_{\mu}}{2\rho \omega_{\mu}}} M_{\mu} , \] (11)

with \( M_{\mu} \) given by

\[ M_{\mu}(\hat{t}) = T^T \cdot [\hat{r}] \cdot S_{\mu} . \]

Explicitly, for the three phonon polarizations we have

\[ M_{h,m,k_l}(\hat{t}) = 2\xi N_h \left\{ -t_y t_k k_h \sin(k_h(z + d/2)) + it_x t_y k_k \cos(k_h(z + d/2)) \right\} e^{ik_l|x} \] (12a)

\[ M_{s,m,k_l}(\hat{t}) = N_s \left\{ -2k_t k_l \cos(k_t d/2) \left[ k_l^2 \left( T^2 + (1 - \zeta T^2) \right) + k_t^2 \left( T^2 + \zeta (1 - T^2) \right) \right] \right. \\
+ k_t k_l (k_t^2 - k_l^2) \left[ \cos(k_t d/2) \cos(\zeta (1 - T^2)) - 2it_x t_z \xi k_t k_l \cos(k_t d/2) \sin(k_t z) - 2it_x t_z \xi (k_t^2 - k_l^2) \cos(k_t d/2) \sin(k_t z) \right) \right\} \] (12b)

\[ M_{a,m,k_l}(\hat{t}) = N_a \left\{ -2k_t k_l \sin(k_t d/2) \sin(k_t z) \left[ k_l^2 \left( T^2 + (1 - \zeta T^2) \right) + k_t^2 \left( T^2 + \zeta (1 - T^2) \right) \right] \right. \\
- k_t k_l (k_t^2 - k_l^2) \left[ \sin(k_t d/2) \sin(k_l z) \left( 1 - \zeta \right) (t_x^2 - t_z^2) \right. \\
+ \left. 8it_x t_z \xi k_t k_l \sin(k_t d/2) \cos(k_t z) + 2it_x t_z \xi (k_t^2 - k_l^2)^2 \sin(k_t d/2) \cos(k_t z) \right\} \] (12c)

where \( k_t \) and \( k_l \) are implicitly determined by the branch number, \( m \), and \( k_l \). Using Fermi’s golden rule, we calculate the phonon absorption and emission rates \( \Gamma_{\mu}^{\text{abs}} \) and \( \Gamma_{\mu}^{\text{em}} \), respectively,

\[ \Gamma_{\mu}^{\text{abs}} = \frac{\pi}{\rho \omega_{\mu}} \frac{\gamma_{\Lambda}^2 \hbar^2}{\epsilon^2} |M_{\mu}|^2 n_{\mu} \delta(\hbar \omega_{\mu} - \epsilon) \] (13a)
\[ \Gamma_{\text{em}}^\mu = \frac{\pi \gamma^2 \Lambda^2}{\rho \omega_{\mu}^2} |M_\mu|^2 (n_\mu + 1) \delta(\hbar \omega_{\mu} - \epsilon), \]  

where \( \epsilon \) is the energy of the TLS, as defined in Section 11 and \( \omega \) is the angular frequency of the phonon.

In an amorphous solid, the orientations of the TLSs are arbitrary, so the relevant quantities for our calculations are the averages of \( \Gamma_{\text{em}}^\mu \) over the directions \( \hat{t} \) of the TLSs. The only quantity that depends on \( \hat{t} \) in Eqs. (13) is \( |M_\mu|^2 \). Additionally, we assume that the distribution of TLSs in the membrane is uniform, which leaves again \( |M_\mu|^2 \) the only quantity dependent on \( z \) in the expressions for the absorption and emission rates. As we are interested in an average scattering probability rather than in a detailed description of where along the \( z \) direction the scattering takes place, we also average \( |M_\mu|^2 \) along \( z \). Denoting by \( \langle \cdot \rangle \) the average over the TLS orientations and the \( z \) variable, we obtain

\[
\langle |M_\mu|^2 \rangle = \frac{C_t}{V} (k_\parallel^2 + k_\perp^2)
\]

\[
\langle |M_s|^2 \rangle = \frac{N_s^2}{d} \left\{ 4C_t |\tilde{k}_\parallel^2 k_\parallel^2 + \tilde{k}_\perp^2| \cos(\tilde{k}_d/2)|^2 \left( \sinh(\kappa_d d) \frac{\sin(k_d d)}{2\kappa_d} + \frac{\sin(k_d d)}{2k_d} \right) + C_t |\tilde{k}_\parallel^2 - k_\parallel^2| \cos(\tilde{k}_d/2)|^2 \left( \frac{\sinh(\kappa_d d)}{2\kappa_d} - \frac{\sin(k_d d)}{2k_d} \right) \right. \\
\left. + C_t |\tilde{k}_\parallel^2 - k_\parallel^2| \sin(\tilde{k}_d/2)|^2 \left( \frac{\sinh(\kappa_d d)}{2\kappa_d} + \frac{\sin(k_d d)}{2k_d} \right) + 2C_t k_d (2k_\parallel^2 - k_\parallel^2 \tilde{k}_d^2) \sin(\tilde{k}_d/2) \frac{\sin(k_d d)}{2k_d} \right\}
\]

\[
\langle |M_a|^2 \rangle = \frac{N_a^2}{d} \left\{ 4C_t |\tilde{k}_\parallel^2 k_\parallel^2 + \tilde{k}_\perp^2| \sin(\tilde{k}_d/2)|^2 \left( \sinh(\kappa_d d) \frac{\sin(k_d d)}{2\kappa_d} - \frac{\sin(k_d d)}{2k_d} \right) + C_t |\tilde{k}_\parallel^2 - k_\parallel^2| \sin(\tilde{k}_d/2)|^2 \left( \frac{\sinh(\kappa_d d)}{2\kappa_d} + \frac{\sin(k_d d)}{2k_d} \right) \right. \\
\left. + C_t |\tilde{k}_\parallel^2 - k_\parallel^2| \sin(\tilde{k}_d/2)|^2 \left( \frac{\sinh(\kappa_d d)}{2\kappa_d} - \frac{\sin(k_d d)}{2k_d} \right) + 2C_t k_d (2k_\parallel^2 + k_\parallel^2 \tilde{k}_d^2) \sin(\tilde{k}_d/2) \frac{\sin(k_d d)}{2k_d} \right\}.
\]

\[ \tau_{\epsilon}^{-1} = \frac{\pi \gamma^2 \Lambda^2}{\rho^2} \coth(\beta \epsilon/2) \sum_{\mu} \frac{1}{\omega_{\mu}} \langle |M_\mu|^2 \rangle \delta(\hbar \omega_{\mu} - \epsilon) \]  

and

\[ \tau_{\mu}^{-1} = \frac{\pi \gamma^2}{\rho \omega_{\mu}} \sum_{\epsilon, u} u^2 \langle |M_\mu|^2 \rangle \tanh(\beta \epsilon/2) \delta(\hbar \omega_{\mu} - \epsilon) \]

\[ = \frac{\pi \gamma^2 V P_0}{\rho \omega_{\mu}} \langle |M_\mu|^2 \rangle \tanh(\beta \hbar \omega/2), \]  

respectively. Here we changed the summation over \( u \) and \( \epsilon \) into a two-dimensional integral and used the TLS density \( \tilde{c} \).

\[ \kappa = \frac{1}{A} \sum_{\mu} \hbar \omega_{\mu} \tau_{\mu} (v_{\mu})^2 \frac{\partial n_{\mu}}{\partial T} \]  

\[ = \frac{\hbar^2 \rho}{16 \pi^2 \gamma^2 V P_0 k_B T^2} \sum_{\mu, \sigma} \int_0^\infty dk_\parallel \left( \frac{\partial \omega_{\mu}}{\partial k_\parallel} \right)^2 \frac{k_\parallel^3}{|M_\mu|^2} \coth(\beta \hbar \omega/2) \frac{\sin^2(\beta \hbar \omega/2)}{\langle |M_\mu|^2 \rangle \sin^2(\beta \hbar \omega/2)}. \]

At an arbitrary temperature, \( \kappa \) has to be calculated numerically. In this paper we give only the analytical low temperature approximation.

**IV. LOW ENERGY EXPANSION: ASYMPTOTIC RESULTS**

We can analytically calculate the scattering times or the thermal properties of the membrane only in the long
wavelength limit, i.e. for the branch \( m = 0 \) for each of the three polarizations of the phonon modes and \( k_0 \ll 1/d \). The calculation of thermal properties in this limit corresponds to a temperature range in which \( k_B T \ll h \omega_c / d \).

First we have to calculate the relaxation times for each polarization.

### A. \( h \) mode

For the lowest branch of the \( h \) mode, \( \omega_{h,0} \) is linear in \( k_\parallel \) and using Eq. \((14a)\), the calculation of \( \tau_{h,0,k_\parallel} \) is straightforward for any \( k_\parallel \),

\[
\tau_{h,0,k_\parallel} = \frac{\hbar \rho c_r^2}{4 \pi^2 P_0 C_\parallel} \frac{1}{\coth(\beta \hbar \omega/2)} \frac{1}{\hbar \omega}.
\]

### B. \( s \) mode

To get a long-wavelength expression of the dispersion relation for the lowest branch of the \( s \) mode, we note that \( k_\parallel = i \xi_\parallel \) takes imaginary values, which turns Eq. \((8b)\) into

\[
\tan(k_\parallel b/2) = \frac{\coth(k_\parallel b/2)}{\coth(\xi_\parallel b/2)} \frac{i \xi_\parallel b}{k_\parallel b/2} = \frac{4 k_\parallel k_\| k_s^2}{(k_\parallel^2 - k_s^2)^2}.
\]

We expand the trigonometric functions in Eq. \((19)\) to leading order and obtain

\[
\omega_{s,0,k_\parallel} = \frac{2 c_t}{c_t} \sqrt{c_t^2 - c_s^2} k_\parallel \equiv c_s k_\parallel.
\]

Using this, we calculate the relaxation time for this branch,

\[
\tau_{s,0,k_\parallel} = \frac{\hbar \rho c_r^2}{4 \pi^2 P_0 C_\parallel} \frac{4 c_t^2 (c_t^2 - c_s^2)}{C_\parallel (c_t^2 - 2 c_s^2) \coth(\beta \hbar \omega/2)} \frac{1}{\hbar \omega}.
\]

### C. \( a \) mode

The antisymmetric modes have a more complicated asymptotic expansion. First let us remark that for the lowest branch and any \( k_\parallel \), both \( k_\parallel = i \xi_\parallel \) and \( k_\parallel = i \xi_\parallel \) take imaginary values, so we write Eq. \((8a)\) in the form

\[
\tan(k_\parallel d/2) = \frac{4 k_\parallel k_\| k_s^2}{(k_\parallel^2 + k_s^2)^2}.
\]

Expanding this equation to the second leading order, we obtain a quadratic dispersion relation for very small \( k_\parallel^2 \),

\[
\omega_{a,0,k_\parallel} = d c_t \sqrt{c_t^2 - c_s^2} k_\parallel^2 \equiv \frac{\hbar}{2 m^*} k_\parallel^2.
\]

Nevertheless, this asymptotic expression is not enough for the calculation of \( \langle |M_{a,0,k_\parallel}|^2 \rangle \), as it turns out that both expression \((10a)\) and expression \((14a)\) are zero in the first and the second leading orders. Therefore, we have to expand to the third leading order to get non-zero results. From Eq. \((8a)\) we obtain

\[
\omega_{a,0,k_\parallel} = \frac{\hbar}{2 m^*} \left( k_\parallel^2 - \frac{27 c_t^2}{90 c_t^2} k_s^4 \right),
\]

from which we finally get

\[
\tau_{a,0,k_\parallel} = \frac{\hbar \rho c_r^2}{4 \pi^2 P_0 C_\parallel} \frac{c_t^2 (c_t^2 - c_s^2)}{C_\parallel (c_t^2 - 2 c_s^2) \coth(\beta \hbar \omega/2)} \frac{1}{\hbar \omega}.
\]

### D. Comparison of the scattering rates and mean free paths

The first thing to observe is that, although the dispersion relations for the \( s \) and \( a \) modes are different in the low \( k_\parallel \) limit, \( \tau_{s,0,k_\parallel} \) and \( \tau_{a,0,k_\parallel} \) are related by the simple equation \( \tau_{s,0,k_\parallel} = 4 \tau_{a,0,k_\parallel} \). In other words, the scattering rate for the \( s \) phonons is 4 times smaller than the scattering rate of \( a \) phonons at the same \( \omega \).

Let us now compare \( \tau_{a,0,k_\parallel} \) with \( \tau_{h,0,k_\parallel} \). For this, we calculate the ratio

\[
\frac{\tau_{h,0,k_\parallel}}{\tau_{a,0,k_\parallel}} = \frac{C_t c_t^2 + C_t c_0^2 (c_t^2 - 2 c_s^2)}{C_t c_t^2 (c_t^2 - c_s^2)} = \frac{1 - (c_t/c_s)^2}{1 - (c_t/c_s)^2 (c_t/c_s)^2}
\]

In any normal material (i.e. with positive Poisson ratio),

![FIG. 2: The ratio \( \tau_{h,0,k_\parallel}/\tau_{a,0,k_\parallel} \) as function of the ratio \( c_t^2/c_s^2 \) for different values of \( C_t/C_t \). The value \( C_t/C_t = 4/3 \) is the minimum possible value and thus all other curves lie above the solid curve in the plot.](image-url)
the ratio \( c_t^2 / c_l^2 \) is restricted to \( 0 < c_t^2 / c_l^2 \leq 1/2 \) and for \( C_t/C_l \) we have \( C_t/C_l = 15/4\xi^2 - 10/\xi + 8 \geq 4/3 \). In Fig. 3 we plot the ratio \( \tau_{h,0,k_l}/\tau_{a,0,k_l} \) as function of \( c_t^2 / c_l^2 \) for different values of \( C_t/C_l \).

We first remark that in the limit \( c_t/c_l \to 0 \), \( \tau_{h,0,k_l}/\tau_{a,0,k_l} = 1 \), independent of the value of \( C_t/C_l \). Increasing \( c_t/c_l \) will result in a decrease of \( \tau_{h,0,k_l}/\tau_{a,0,k_l} \), until a minimum is reached at \( (c_t/c_l)^2 = 1 - \sqrt{1 - (C_t/C_l)^{-1}} \), which lies between 0 and 1/2. Afterwards \( \tau_{h,0,k_l}/\tau_{a,0,k_l} \) increases monotonically until it reaches the value \( (C_t/C_l)/2 \) for \( (c_t/c_l)^2 = 1/2 \). As \( \tau_{h,0,k_l}/\tau_{a,0,k_l} \) increases monotonically with \( C_t/C_l \), we conclude that \( \tau_{h,0,k_l} < \tau_{a,0,k_l} \) for any \( c_t/c_l \), as long as \( C_t/C_l < 2 \). For \( C_t/C_l \geq 2 \), \( \tau_{h,0,k_l} \) can be either smaller or greater than \( \tau_{a,0,k_l} \), depending on whether \( (c_t/c_l)^2 \) is smaller or greater than \( C_t/C_l \), respectively. A typical value for \( (c_t/c_l)^2 \) in SiN is 0.36, which means that \( \tau_{h,0,k_l} < \tau_{a,0,k_l} \) as long as \( C_t/C_l \) is smaller than 2.78.

When comparing \( \tau_{a,0,k_l} \) with \( \tau_{h,0,k_l} \), we encounter a similar situation. As \( \tau_{a,0,k_l} = 4\tau_{a,0,k_l} \) the ratio \( \tau_{a,0,k_l}/\tau_{a,0,k_l} \) except for the fact that the critical value for \( C_t/C_l \) is 8, i.e., \( \tau_{a,0,k_l} \) is always smaller than \( \tau_{a,0,k_l} \), if \( C_t/C_l < 8 \), and can be either smaller or greater than \( \tau_{a,0,k_l} \) for \( C_t/C_l = 8 \). For the SiN typical value, \( (c_t/c_l)^2 = 0.36 \), we have \( \tau_{h,0,k_l} \leq \tau_{a,0,k_l} \) as long as \( C_t/C_l < 17.6 \).

More interesting than the scattering rates, is to compare the phonon mean free paths, since these can be directly measured experimentally. For this, let us first use the dispersion relations \( 20 \), \( 23 \), and \( \omega_{h,0,k_l} = c_l k_l^2 \) to write the expressions for the mean free paths:

\[
\begin{align*}
\tau_{h,0,k_l} &= c_t \tau_{a,0,k_l} = \frac{\hbar c_t^3}{\pi \gamma^2 P_0 C_t} \frac{1}{\coth(\beta \hbar \omega / 2)} \quad (27a) \\
&= \frac{\hbar c_t^3}{\pi \gamma^2 P_0 C_t} \frac{1}{\coth(\beta \hbar c_l k_l / 2)} \quad (27b) \\
\tau_{a,0,k_l} &= c_s \tau_{a,0,k_l} = \frac{\hbar c_s^3}{\pi \gamma^2 P_0 C_s} \frac{1}{\coth(\beta \hbar c_s k_l / 2)} \quad (28a) \\
&= \frac{\hbar c_s^3}{\pi \gamma^2 P_0 C_s} \frac{1}{\coth(\beta \hbar c_s k_l / 2)} \quad (28b) \\
\tau_{a,0,k_l} &= \frac{2\hbar \omega}{m^2 \tau_{a,0,k_l}} = \frac{\hbar c_t^2}{\pi \gamma^2 P_0} \frac{2}{C_s} \left(\frac{1 - c_t^2 / c_l^2}{c_t} \right)^{1/4} \coth(\beta \hbar \omega / 2) \sqrt{c_t} \\
&= \frac{\hbar c_t^2}{\pi \gamma^2 P_0 C_s} \frac{2 \coth \left( \frac{\beta \hbar \omega}{2} \right)}{\coth(\beta \hbar \omega / 2)} \sqrt{1 - c_t^2 / c_l^2} \quad (29a) \\
&= \frac{\hbar c_t^2}{\pi \gamma^2 P_0 C_s} \frac{2 \coth \left( \frac{\beta \hbar \omega}{2} \right)}{\coth(\beta \hbar \omega / 2)} \sqrt{1 - c_t^2 / c_l^2} \quad (29b)
\end{align*}
\]

A way to determine the mean free path of phonons is to measure the resonant attenuation of ultra-sound, propagating along the membrane. If this is experimentally impossible, another way to determine the material parameters is to make acoustic measurements on thicker and wider membranes. Note however that elastic waves attenuate not only because of resonant scattering of phonons (Eqs. 24, 25), but also due to energy relaxation. Nevertheless, since we are interested here in the thermal properties of the membranes, only the resonant scattering is important and we disregard the energy relaxation mechanism.

To analyze the results \( 27 \), \( 28 \), and \( 29 \) in more detail, we expressed the mean free paths both in terms of the angular frequency and in terms of \( k_l \). If the elastic modes of different polarizations are produced with the same \( \omega \), then we should compare the mean free paths as given by the expressions \( 27a, 28a \), and \( 29a \), which we denote as \( \tau_{a,0,\omega} \). For example, \( \tau_{h,0,\omega} / \tau_{a,0,\omega} = (\tau_{h,0,\omega} / \tau_{a,0,\omega}) (c_t / c_s) \) which is smaller than \( (\tau_{h,0,\omega} / \tau_{a,0,\omega}) \) in any material. The discussion we made above about \( \tau_{h,0,\omega} / \tau_{a,0,\omega} \) applies here too.

The expressions \( 29 \) for \( \tau_{a,0,\omega} \) are very different from the ones for \( \tau_{h,0,\omega} \) and \( \tau_{a,0,\omega} \). Nevertheless, the expressions \( 27 \), \( 28 \), and \( 29 \) are calculated for \( k_l \ll 1/d \), which means that \( \omega d \ll 2\pi/k_l \omega \), which implies \( \sqrt{\omega d / c_t} \ll 1 \). Taking this into account when we compare the expressions for \( h_{h,0,\omega} / h_{a,0,\omega} \) and \( l_{a,0,\omega} \), at the same \( \omega \), we conclude that, as a function of frequency, for low enough frequencies the antisymmetric Lamb modes have the shortest mean free path. This is a consequence of the fact that the group velocity of the modes decreases to zero as \( k_l \) decreases.

If we compare \( l_{h,0,k_l} \) and \( l_{a,0,k_l} \) as functions of \( k_l \), we see that \( l_{h,0,k_l} / l_{a,0,k_l} = (\tau_{h,0,k_l} / \tau_{a,0,k_l}) \cdot \left[ \coth(\beta \hbar c_t k_l / 2) / \coth(\beta \hbar c_s k_l / 2) \right] \), which is bigger than \( \tau_{h,0,k_l} / \tau_{a,0,k_l} \), since \( c_t < c_s \) implies \( \coth(\beta \hbar c_t k_l / 2) > \coth(\beta \hbar c_s k_l / 2) \). Comparing \( l_{a,0,k_l} \) with the expressions \( 27 \) and \( 28 \), we observe, for example, that both \( l_{a,0,k_l} / l_{h,0,k_l} \) and \( l_{a,0,k_l} / l_{a,0,k_l} \) are proportional to \( \coth(\beta \hbar c_s,0,k_l / 2) / \coth(\beta \hbar c_s,0,k_l / 2) \). But again, for long wavelengths, due to the quadratic dependence of \( \omega_{a,0,k_l} \) on \( k_l \), we have \( \omega_{a,0,k_l} \ll \omega_{a,0,k_l} \). Moreover, \( \coth(\beta \hbar \omega / 2) \sim 1 / x \) for \( x \to 0 \), so both \( l_{a,0,k_l} / l_{h,0,k_l} \) and \( l_{a,0,k_l} / l_{a,0,k_l} \) are proportional to \( 1/k_l \) and become very big in the limit of long wavelengths. In conclusion, as function of \( k_l \) in the limit \( d k_l \ll 1 \), the antisymmetric modes have a much longer mean free path than the symmetric and the horizontal shear modes with the same \( k_l \).

E. Calculation of the heat conductivity

Now we calculate the heat conductivity in the limit of low temperature. In that limit, only the lowest branch of each polarization will be occupied and we can write Eq.
where the lower limits \( \omega_{s,0}^* \) were introduced for the reasons that will become clear immediately. Using Eqs. (27) for the mean free paths we express \( \kappa \) as a sum of three contributions:

\[
\kappa = \frac{k_B^2 \rho c_T^2}{16\pi^2 \hbar^2 P_0} T \left[ \frac{I(x_{h,0}^*)}{C_t} + \frac{I(x_{s,0}^*)}{C_s} + 2 \frac{I(x_{a,0}^*)}{C_a} \right] ,
\]

(31) where \( x_{s,0}^* \equiv \beta \hbar \omega_{s,0}^* \) and by \( I(x) \) we denoted the integral

\[
I(x) \equiv \int_x^\infty dy \frac{y^2 \text{coth}(y/2)}{\sinh^2(y/2)} = \frac{4x^2 e^x}{(e^x - 1)^2} + \frac{8x}{e^x - 1} - 8 \ln(1 - e^{-x}).
\]

(32)

Note that, although the mean free paths for the \( h \) and \( s \) modes have different functional dependences on \( \omega \) than the mean free path for the \( a \) modes, the integrand in Eq. (31) is the same for all three modes. The role of the lower cut-off in Eq. (30) becomes obvious when we look at Eq. (32): the integral \( I(x) \) has a logarithmic divergence in \( x = 0 \).

If the cut-off is small enough, then we can approximate \( I(x) \) by

\[
I(x) \approx 12 - 8 \ln(x)
\]

(33)

and inserting this into (31) we obtain

\[
\kappa = \frac{k_B^2 \rho c_T^2}{4\pi^2 \hbar^2 P_0} T \left[ \frac{3 - 2 \ln(\beta \hbar \omega_{s,0}^*)}{C_t} + \frac{3 - 2 \ln(\beta \hbar \omega_{a,0}^*)}{C_s} + \frac{2[3 - 2 \ln(\beta \hbar \omega_{a,0}^*)]}{C_a} \right].
\]

(34)

where the first, the second, and the third terms in the square brackets above give the contributions of the \( h \), \( s \), and \( a \) phonon modes to the heat conductivity. The above expression leads to the temperature dependence \( \kappa \propto T(a + b \ln T) \) and this dependence is a hallmark of the TLS-limited heat conductance at low temperature.

For a numerical estimate let us use for the cut-off the finite size of the membrane, which limits the wave vectors to values of the order of \( 2\pi / \sqrt{A} \). For the typical experimental parameters \( T = 0.1 \text{ K}, \sqrt{A} = 400 \mu \text{m} \) and \( d = 200 \text{ nm} \), we have \( \ln(x_{h,0,2\pi/L}) \approx -4.9 \), \( \ln(x_{s,0,2\pi/L}) \approx -4.4 \), and \( \ln(x_{a,0,2\pi/L}) \approx -11.4 \). But since \( C_a = 4C_s \) (see Eqs. (21) and (23)), the contributions of all the phonon polarizations to the heat conductivity are of the same order.

V. CONCLUSIONS

We used the model introduced in Ref. [13] to calculate the scattering of the elastic modes in a thin, amorphous membrane. We modeled the scattering centers in the membrane by an ensemble of TLSs with the same properties and distribution over energy splitting and asymmetry as the TLSs in a bulk material. If this assumption is valid remains to be checked by experiment. We obtained the expressions for the TLS relaxation time (15), for the phonon scattering time (16), and for the heat conductivity \( \kappa \) (17).

For general temperatures, the heat conductivity and the scattering times have to be calculated numerically. We calculated analytical low temperature approximations and compared the mean free paths of different phonon polarizations. In this way we observed that the contribution of the lowest branches of the phonon modes to the heat conductivity are logarithmically divergent at \( k_B T \rightarrow 0 \). This could be a reason for which in some experiments a radiative heat transport is observed. Nevertheless, there is a natural lower cut-off of \( k_B T \rightarrow 0 \) due to the finite size of the membrane. This cut-off renders \( \kappa \) finite, which, in the low temperature limit behaves like \( \kappa \propto T(a + b \ln T) \). This behavior is a hallmark of the TLS-limited heat conductance at low temperature.

Due to the dispersion relations of the phonon modes, the TLSs distribution in the low energy limit has a bigger impact on the heat conductivity in thin membranes than in bulk materials. If we for instance modify the distribution (8) into

\[
P^t(\epsilon, u) = \frac{P_0}{e^{\alpha u} \sqrt{1 - u^2}}
\]

with an extra energy dependence, \( e^{-\alpha} \), we make the expression (30) for \( \kappa \) converge even in the \( 1/\omega_{s,0}^* \rightarrow 0 \) limit, which leads to a low temperature asymptotic dependence of \( \kappa \propto T^{1+\alpha} \). But if this is the situation or not has to be decided experimentally.
