ABSTRACT In this article, the stabilization issues for probabilistic Boolean Networks (PBNs) with time delays are discussed. This article’s objective is designing an efficient algorithm to choose suitable nodes to be pinning controlled for PBNs with time delays. By using the semi-tensor product (STP) of matrices, a PBN with time delays can be converted into a discrete-time linear system, and the transition matrix also can be obtained. Then, the necessary and sufficient conditions in the form of algebraic expression are given for the existence and solvability of the pinning feedback controllers with minimum pinning nodes for PBNs with time delays. Besides, three algorithms are proposed for designing and solving minimum pinning controllers.

INDEX TERMS Probabilistic Boolean networks, pinning control, time delays, semi-tensor product.

I. INTRODUCTION

Boolean Networks (BNs), which were first proposed by Kauffman in 1969 [1], are a kind of logical dynamical models to describe gene regulatory networks (GRNs) [2]. As we all know, in a gene regulatory network, each gene can be expressed (1) or not expressed (0), which corresponds to binary state variables. A BN is a deterministic model to simulate the evolution of binary state variables. What’s more, Boolean Networks have been widely studied in state estimation [3], logical networks [4], neural networks [5], etc. Recently, the STP of matrices was introduced by Cheng’s team. With the help of STP, a BN can be transformed into a discrete-time linear system. Moreover, a logic function can be represented by an algebraic form with STP. This new matrix product was introduced to the study of BNs in many fields, such as the controllability, event-triggered control, etc., which have been studied in [6]–[11].

To better handle of biological system uncertainty, Shmulevich etc. in [12] generalized the concept of BNs for application to probabilistic Boolean Networks (PBNs). In general, the PBNs can be seen as a kind of randomly switched BNs in given sets of BNs. Every BN is chosen with an definite probability. Many interesting results have been obtained for PBNs and probabilistic Boolean control networks (PBCNs), such as stability and stabilization [13], optimal control [4], controllability [14], and pinning control [15], etc.

Stability and stabilization are two important problems in BNs. For example, the apoptotic pathway can be activated to allow an organism to clear damaged or unwanted cells by combining with tumor necrosis factor (TNF) to death receptor tumor necrosis factor receptor 1 (TNFR1) [16]. Without TNF, cells can be bistable in two different states: survival and initiation of apoptosis [17]. However, the decision on one state or the other mainly depends on the initial conditions of random variation in each cell, and it can be seen as a stability problem in PBNs. Meanwhile, time delays are unavoidable in many real world systems, such as biological, physiological systems, and economic, and so on [18]–[20]. For GRNs, the direction of gene evolution is uncertain due to the possibility of gene mutation. Hence, PBNs with time delays can be better to simulate the real biological systems and GRNs in some cases. Thus, in this article, we will discuss the stabilization of PBNs with time delays.

In [21], BNs realize stabilization via state feedback control. Different from feedback control, only a small part of nodes are selected to be pinning controlled, which reduce the cost of the control effectively. A natural question in pinning control is how to select the nodes to be pinned. In [22], an algorithm is proposed to solve the minimum number of pinning...
controllers. Recently, minimizing controlled nodes to realize stabilization of BNs has been investigated deeply in [23]. Moreover, the stochastic networks can realize stabilization via minimum pinning controlled nodes, which has been studied in [24]. In [25], BNs with time delays realize stabilization via the pinning control. Thus, for a PBNs with time delays, how to stabilize via the pinning control and how to solve the minimum number pinning nodes to stabilize system are worth considering. Inspired by above works, the stabilization of PBNs with time delays via pinning control is investigated in this article.

The difficulties of this article are mainly two folds. 1) How to select pinning nodes for a PBN with time delays? Since a PBN with time delays is a dynamics system with random variables and multiple time delays, which make the pinning control problem for PBNs with time delays more complicated and challenging than that of BNs. 2) How to solve the minimum number of pinned nodes for a PBN with time delays through the algebraic method? In [22] and [26], the stabilization issue of BNs via minimum pinned nodes is solved through the graph theory method, rather than the algebraic method. Thus, it is a challenge to obtain corresponding results via the algebraic method. To overcome these difficult problems, inspired by the work of [24] and [25], we will take three steps to solve these difficulties. (i) Changing columns of the structure matrix to obtain the desired structure matrix. Thus, we propose a new algorithm to obtain the desired structure matrix. (ii) Selecting the pinning nodes via the columns of new structure matrix directly. The existence of the pinning feedback controllers for PBNs with time delays is considered, and the corresponding necessary and sufficient conditions in the form of algebraic expression are given. (iii) Choosing the minimal number pinning nodes by an efficient way. Moreover, an effective algorithm is proposed to calculate the minimum number of pinning controllers.

Notations: $\delta_h := \{\delta^k_h \mid 1 \leq k \leq h\}$, where $\delta^k_h$ is the $k$th column of the identity matrix $I_h$. $D := \{1, 0\}$. $I_h$ and $0_h$ denote the column vector of length $n$, all of the elements are equal to 1 and 0 respectively. $M_{r \times h}$ stands for the set of all $r \times h$ matrices and $M^k_{r \times h}$ stands for the set of matrix $A$ where $A_{ij} = (a_1, a_2, \ldots, a_h)^T$, $1 \leq i \leq r$ and $1 \leq j \leq h$. We denote $\text{Row}_i(W(\text{Col}_i(W)))$ stands for the $i$th row(column) of matrix $W_{r \times h}$ and $\text{Row}(W(\text{Col}(W)))$ is the set of rows(columns) of matrix $W_{r \times h}$. A matrix $W \in M_{r \times h}$ is called a logical matrix if its columns $\text{Col}(W) \subset \Delta_r$. Moreover, we define the set of $r \times h$ logical matrices as $L_{r \times h}$. $W = [\delta_{11}, \delta_{12}, \ldots, \delta_{1h}, \delta_{21}, \delta_{22}, \ldots, \delta_{2h}, \ldots, \delta_{h1}, \delta_{h2}, \ldots, \delta_{hh}]$ is denoted by $W := \delta_j[k_1, k_2, \ldots, k_h]$. $p = (k_1, k_2, \ldots, k_h)^T$ is called a $h$-dimensional probabilistic vector if $k_r \geq 0, r = 1, 2, \ldots, h$ and $\sum_{r=1}^h k_r = 1$. We define the set of $h$-dimensional probabilistic vectors as $P_r$. For a probabilistic vector $p = (k_1, k_2, \ldots, k_h)^T$, we denote an operator ($p$) = $[\delta_p(k_r)]$, for $r = 1, 2, \ldots, h$. For a matrix $W \in M_{r \times h}$, if its columns $\text{Col}(W) \subset P_r$, then this matrix is called a probabilistic matrix. Moreover, we define the set of $r \times h$ probabilistic matrices as $P_{r \times h}$.

II. PRELIMINARIES

A. STP OF MATRICES

Definition 1: [27] For matrices $W \in M_{r \times h}$ and $Q \in M_{s \times t}$, then the STP of $W$ and $Q$ is

$$W \times Q = (W \otimes I_{q/h})(Q \otimes I_{q/s}).$$

Here $\otimes$ is the Kronecker product of matrices and $q$ is the least common multiple of $h$ and $s$ ($q = lcm(h, s)$).

Remark 1: Since STP is a generalization of the general matrix products, this notation $\times$ can be omitted in the following discussion if no confusion arises.

Lemma 1: [27]

1) Let $X \in \mathbb{R}^l$ be a row vector and a matrix $A \in M_{m \times n}$, we have $A \times X = X \times (I_l \otimes A)$;

2) Let $X \in \mathbb{R}^l$ be a column vector and a matrix $A \in M_{m \times n}$, we have $X \times A = (I_l \otimes A) \times X$.

Definition 2: [27] Define a matrix:

$$Q_{[r,h]} = \delta_{rh}[1, r + 1, \ldots, (h - 1)r + 1, 2, r + 2, \ldots, (h - 1)r + 2, \ldots, r, 2r, \ldots, rh] \in L_{rh \times rh}. \tag{1}$$

then for column vectors $a \in \mathbb{R}^r$ and $b \in \mathbb{R}^h$, we have $Q_{[b,r]} \times b \times a = a \times b$.

Lemma 2: [27] Define a logical matrix

$$\Phi_n = \text{diag}(\delta_{2^0_1}, \delta_{2^1_2}, \ldots, \delta_{2^n_{2^n}}) = \delta_{2^n} = [2^n + 2, \ldots, 2^{2^n}],$$

and let $X \in \Delta_{2^n}$. Then, $X \times X = \Phi_n X$.

B. ALGEBRAIC REPRESENTATIONS OF PROBABILISTIC BOOLEAN NETWORKS WITH TIME DELAYS

Letting $\text{True} = 1 \sim \delta^1_1$, $\text{False} = 0 \sim \delta^1_2$. Then we can express the logical function by using STP of matrices.

Lemma 3: [27] A logical function $h(L_1, \ldots, L_r)$ with logical arguments $L_1, \ldots, L_r \in \Delta_2$ can be expressed in a multi-linear form as

$$h(L_1, \ldots, L_r) = M_h L_1 L_2 \ldots L_r,$$

where $M_h \in L_{2 \times 2^r}$ is unique. Moreover, we define the matrix $M_h$ as the structure matrix of $h$.

A PBN with time delays is described as

$$x_h(t+1) = f_h(x_1(t), \ldots, x_r(t), x_1(t-1), \ldots, x_r(t-1), \ldots, x_1(t-\tau), \ldots, x_r(t-\tau)), \ h = 1, \ldots, r. \tag{2}$$

where $x_h(t) \in D$ is the state of node $h$ at time $t$, $h = 1, 2, \ldots, r$, and $\tau$ is a positive integer.

In system (2), $f_h$ is randomly selected from a given finite set of Boolean functions $\Omega = \{f^1_h, f^2_h, \ldots, f^{k_h}_h\}$, and $f^s_h : D^{(\tau+1)} \mapsto D$, $s = 1, 2, \ldots, k_h$. 

VOLUME 8, 2020

154051
We suppose that $P(f_h = f^1_h) = p^1_h$, $s = 1, 2, \ldots, k_h$, where $\sum_{s=1}^{k_h} p^s_h = 1$, and $x(t) = \psi^\tau_{t=1} x_h(t)$. Then, system (2) can be converted into an algebraic form as

$$x_h(t + 1) = M_{h,k}(x(t - 1) \ldots x(t - \tau),$$

where $M_{h} \in \mathbb{L}_{2 \times 2^{t+1}}$ is selected from a matrices’ set $\{M_{h}^{1}, M_{h}^{2}, \ldots, M_{h}^{k_h}\}$ and $M_{h}^{s}$ are logical matrices of $f^s_h$, $s = 1, 2, \ldots, k_h$, respectively. Then, $P(M_{h} = M_{h}^{s}) = p^{s}_h$, $s = 1, 2, \ldots, k_h$.

Based on the above discussion, the evolution of the state expectation can be obtained as follows

$$E[x(t + 1)] = M E[x(t) \ldots x(t - \tau)]$$

where $M = \tilde{M}_{1} \ast \cdots \ast \tilde{M}_{r} \in \mathbb{P}_{2^r \times 2^{t+1}}$ and $\ast$ is Khatri-Rao product.

Definition 3: A probabilistic Boolean networks with time delays is globally stable with probability one to a state $\tilde{x} = \delta_q^{\tau}$, for any sequence of initial states $x_{0}, x_{-1}, \ldots, x_{-\tau} \in \Delta_{2^r}$, if there exists a positive integer $T \in \mathbb{Z}_+$, such that $P(x(t) = \tilde{x} | x(0) = x_{0}, \ldots, x(-\tau) = x_{-\tau}) = 1$ for all $t \geq T$.

Based on the discussion of remark 1 of [28], for obtaining the condition of the globally stable to a state with probability one of PBNs (2), we only need to study the globally stable of system (4).

III. MAIN RESULTS

In this section, the stabilization of PBCNs with time delays is considered by designing pinning controllers. We need to design a algorithm to get some suitable controlled nodes. Based on the above discussion, the evolution of the state can be obtained as follows

$$E[x(t + 1)] = \tilde{M} E[x(t) \ldots x(t - \tau)].$$

where $\tilde{M} = \tilde{M}_{1} \ast \cdots \ast \tilde{M}_{r}$ and $\ast$ is Khatri-Rao product.

Then system (2) with controllers becomes the following system

$$x_h(t + 1) = F_s(x_h(t), f_s(x_1(t), \ldots, x_r(t), x_1(t - 1), \ldots, x_1(t - \tau), \ldots, x_r(t - \tau)))$$

$$s = 1, 2, \ldots, l,$$

where $F_s$ is a logical function of variables $u_s(t)$ and $f_s$, $u_s(t)$ is the state feedback controller of $x(t), \ldots, x(t - \tau)$, $s = 1, 2, \ldots, l$.

According to Lemma 3, there exists a matrix $H_s \in \mathbb{L}_{2 \times 2^t}$, where $u_s(t) = H_s x(t) \ldots x(t - \tau)$. Furthermore, since $F_s$ is a logical function of variables $u_s(t)$ and $f_s$, there exists a logical matrix $L_s \in \mathbb{L}_{2^t \times 2^t}$, where $x_h(t + 1) = L_s H_s x(t) \ldots x(t - \tau) M_{h,x}(t) \ldots x(t - \tau) = L_s H_s (I_{2^t} \otimes M_{s}) \Psi_{(t+1)} E[x(t) \ldots x(t - \tau)]$, where $P(M_{s} = M_{s}^{s}) = P_{s}^{s}$.

From (3), the following formula can be obtained

$$E[x_s(t + 1)] = E[E[x_s(t + 1) | M_{s}]]$$

$$= \sum_{q=1}^{k_s} p^q_s E[L_s H_s (I_{2^t} \otimes M_{s}^{q}) \Psi_{(t+1)} E[x(t) \ldots x(t - \tau)], s = 1, 2, \ldots, l].$$

Hence, systems (6) can be transformed to be

$$E[x_s(t + 1)] = \tilde{M}_s E[x(t) \ldots x(t - \tau)]$$

where $\tilde{M}_s = \tilde{M}_1 \ast \cdots \ast \tilde{M}_r$, and

$$\tilde{M}_s = \begin{cases} \tilde{M}_{s,1}, & s = 1, \ldots, l, \\ \tilde{M}_{s,2}, & s = l + 1, \ldots, r. \end{cases}$$

A. THE PINNED NODES OF PBNS WITH DELAYS

Definition 4: For two probabilistic vectors $\psi, \omega \in \mathbb{P}_{1}$, where $\psi = (\psi_1, \psi_2, \ldots, \psi_r)^T$ and $\omega = (\omega_1, \omega_2, \ldots, \omega_r)^T$. Then,

$$Row_s(\psi \circ \omega) = \psi_s \otimes \omega_s, s = 1, \ldots, r,$$

where

$$\psi_s \otimes \omega_s = \begin{cases} 1, & \psi_s \omega_s > 0, \\ 0, & \text{else}. \end{cases}$$
Let \( \hat{x} = \delta_{2r}^q \) be the pinning objective state and \( \delta_{2r}^q \) be the new structure matrix form \( M \). Then, we define a sequence of set \( \Omega_k \) as follows

\[
\Omega_1(\delta_{2r}^h) = \left\{ \delta_{2r}^s \mid M \delta_{2r}^s \right\}, \quad s = 1, \ldots, 2^{(r+1)}
\]

\[
\Omega_{k+1}(\delta_{2r}^h) = \left\{ \delta_{2r}^s \mid \Gamma \circ (1_{2r}^c, \delta_{2r}^s) = 0_{2r}^s \right\}, \quad \delta_{2r}^i \in \Omega_k(\delta_{2r}^h)
\]

\[
\Gamma = 1_{2r+1} \forall \delta_{2r+1} \cap 1_{2r} \forall \delta_{2r} \cap \delta_{2r+1}
\]

where \( Y_1 = M \delta_{2r}^1, \ldots, Y_t = M \delta_{2r}^{t-1} \). Then, the logical functions \( \Gamma \) and \( \delta_{2r+1} \) can be obtained by the above algorithm. Then, it holds that

\[
\tilde{M} = \hat{M}(\sum r_i \delta_{2r+1}^s) = \sum r_i \delta_{2r+1}^s \in \mathcal{P}_{2r+1}(\delta_{2r+1}^h)
\]

where \( \mathcal{P}_{2r+1}(\delta_{2r+1}^h) \) is a column vector with all elements belonging to \( D \). Thus, \( \Gamma \) can be a linear combination of \( \delta_{2r+1}^s \in \mathcal{P}_{2r+1}(\delta_{2r+1}^h) \). Thus, there exists \( r_s \in [0, 1] \) such that

\[
\Gamma = \sum r_i \delta_{2r+1}^s
\]

which implies that \( \Gamma \in \mathcal{P}_{2r+1}(\delta_{2r+1}^h) \). That is to say, \( \Gamma \) can reach \( \delta_{2r+1}^h \) in \( t - 1 \) steps. From (10), it holds that \( \delta_{2r+1}^h \) can reach \( \delta_{2r+1}^h \) in \( t \) steps.

**THEOREM 1:** Suppose that the structure matrix of (4) is \( M \), and \( \hat{M} \) is changed to \( \tilde{M} \) by the above algorithm. Then, the PBN with delays is globally stabilized to \( \delta_{2r}^q \) with probability one.

**Proof:** For all initial states \( \nu_{i-1} x_i = \delta_{2r+1}^h \), using the above algorithm, such that \( \delta_{2r+1}^h \in \Xi(\delta_{2r+1}^h) \). The result implies that there exist \( T \in T \) such that \( \delta_{2r+1}^h \in \Xi(\delta_{2r+1}^h) \). Next, we will prove that \( \delta_{2r+1}^h \) can reach \( \delta_{2r+1}^h \) in \( T \) steps by mathematical induction.

For \( T = 1 \), \( \delta_{2r+1}^h \in \Xi(\delta_{2r+1}^h) \), then \( \tilde{M} \delta_{2r+1}^h = \delta_{2r}^h \), where \( \tilde{M} \) is the new structure matrix form \( M \).

Assuming that when \( T = t - 1, t \geq 2 \), the Theorem 1 holds. For \( T = t \), assuming \( \delta_{2r+1}^h \in \Xi(\delta_{2r+1}^h) \), then

\[
\Gamma \circ (1_{2r+1} - \sum \delta_{2r+1}^h) = 0_{2r+1}
\]

where \( \Gamma \) is a \( 2^{(r+1)} \)-dimensional probabilistic vector and \( 1_{2r+1} - \sum \delta_{2r+1}^h \in \Xi(\delta_{2r+1}^h) \) is a column vector with all elements belonging to \( D \). Thus, \( \Gamma \) can be a linear combination of \( \delta_{2r+1}^h \). Thus, there exists \( r_s \in [0, 1] \) such that

\[
\Gamma = \sum r_i \delta_{2r+1}^s
\]

which implies that \( \Gamma \in \Xi(\delta_{2r+1}^h) \). That is to say, \( \Gamma \) can reach \( \delta_{2r+1}^h \) in \( t - 1 \) steps. From (10), it holds that \( \delta_{2r+1}^h \) can reach \( \delta_{2r+1}^h \) in \( t \) steps.

**B. THE DESIGN OF PINNING FEEDBACK CONTROLLERS**

From (6), we can get the following expressions:

\[
\left\{ 
\begin{array}{c}
\hat{M}_1 = L_1 H_1 (I_{2r+1} \otimes \hat{M}_1) \Phi_r (t+1) \\
\hat{M}_2 = L_2 H_2 (I_{2r+1} \otimes \hat{M}_2) \Phi_r (t+1) \\
\vdots \\
\hat{M}_l = L_l H_l (I_{2r+1} \otimes \hat{M}_l) \Phi_r (t+1)
\end{array}
\right.
\]

Thus, if we can solve \( L_i, H_i, i = 1, 2, \ldots, l \) from (12), then the logical functions \( F_i, i = 1, 2, \ldots, l \) and feedback
controllers \(u_i(t)\), \(i = 1, 2, \ldots, l\) can be solved. Consequently, system (6) can be globally stabilized with probability one to the desired state \(\delta^T_{y^0}\) by Theorem 1.

**Theorem 2:** System of equation (12) is solvable if and only if the columns of \(\tilde{M}_i\) \((i = 1, 2, \ldots, l)\) belong to two sets of \(\Psi_1, \Psi_2, \Psi_3, \Psi_4\) at most, where \(\Psi_1, \Psi_2, \Psi_3, \Psi_4\) as follows

\[
\begin{align*}
\Psi_1 &= \{\text{Col}_j(\tilde{M}_i) | \text{Col}_j(\tilde{M}_i) = \text{Col}_j(\tilde{M}_i) \neq (0, 1)^T \lor (1, 0)^T\}, \\
\Psi_2 &= \{\text{Col}_j(\tilde{M}_i) | \text{Col}_j(\tilde{M}_i) = (1, 1)^T - \text{Col}_j(\tilde{M}_i)\}, \\
\Psi_3 &= \{\text{Col}_j(\tilde{M}_i) | \text{Col}_j(\tilde{M}_i) = (0, 1)^T\}, \\
\Psi_4 &= \{\text{Col}_j(\tilde{M}_i) | \text{Col}_j(\tilde{M}_i) = (1, 0)^T\}.
\end{align*}
\]

*Proof:* (Necessity) Assume that

\[
L_i = \begin{bmatrix}
\eta_1 & \eta_2 & \eta_3 & \eta_4 \\
1 - \eta_1 & 1 - \eta_2 & 1 - \eta_3 & 1 - \eta_4
\end{bmatrix},
\]

\[
H_i = \begin{bmatrix}
\theta_1 & \theta_2 & \cdots & \theta_2(\tau + 1) \\
1 - \theta_1 & 1 - \theta_2 & \cdots & 1 - \theta_2(\tau + 1)
\end{bmatrix},
\]

\[
\tilde{M}_i = \begin{bmatrix}
\lambda_1 & \lambda_2 & \cdots & \lambda_2(\tau + 1) \\
1 - \lambda_1 & 1 - \lambda_2 & \cdots & 1 - \lambda_2(\tau + 1)
\end{bmatrix},
\]

\[
\tilde{\tilde{M}}_i = \begin{bmatrix}
\mu_1 & \mu_2 & \cdots & \mu_2(\tau + 1) \\
1 - \mu_1 & 1 - \mu_2 & \cdots & 1 - \mu_2(\tau + 1)
\end{bmatrix},
\]

where \(\eta_s, \theta_s \in D = \{0, 1\}, s = 1, 2, 3, 4, q = 1, \ldots, 2^{(\tau+1)}\) and \(\lambda_s, \mu_s \in [0, 1], s = 1, \ldots, 2^{(\tau+1)}\). Then,

\[
L_i H_s (I_{2(\tau+1)} \otimes \tilde{M}_i) \Phi_{\tau}(t+1) = L_i (H_i \otimes I_{2(\tau+1)} \otimes \tilde{M}_i) \Phi_{\tau}(t+1) = L_i (H_i \otimes \tilde{M}_i) \Phi_{\tau}(t+1) = \begin{bmatrix}
\eta_1 & \eta_2 & \eta_3 & \eta_4 \\
1 - \eta_1 & 1 - \eta_2 & 1 - \eta_3 & 1 - \eta_4
\end{bmatrix} \\
\times \begin{bmatrix}
\theta_1(1 - \lambda_1) & \theta_2(1 - \lambda_2) & \cdots & \theta_2(\tau + 1) \\
(1 - \theta_1)1 - \lambda_1 & (1 - \theta_2)1 - \lambda_2 & \cdots & (1 - \theta_2(\tau + 1))1 - \lambda_2
\end{bmatrix} = \begin{bmatrix}
\mu_1 & \mu_2 & \cdots & \mu_2(\tau + 1) \\
1 - \mu_1 & 1 - \mu_2 & \cdots & 1 - \mu_2(\tau + 1)
\end{bmatrix},
\]

\[
\text{Equations can be classified into 3 parts:}
\]

\[
\begin{align*}
(1) &: \mu_s = \lambda_s \\
(2) &: \mu_s = 1 - \lambda_s \\
(3) &: \mu_s \neq \lambda_s \text{ and } \mu_s \neq 1 - \lambda_s
\end{align*}
\]

For (1), if \(\theta_s = 0\), then \(\eta_3 = 1, \eta_4 = 0\). If \(\theta_s = 1\), then \(\eta_1 = 1, \eta_2 = 0\).

For (2), if \(\theta_s = 0\), then \(\eta_3 = 0, \eta_4 = 1\). If \(\theta_s = 1\), then \(\eta_1 = 0, \eta_2 = 1\).

For (3), if \(\theta_s = 0\), then \(\eta_3 = 1, \eta_4 = 0\). If \(\theta_s = 1\), then \(\eta_1 = 1, \eta_2 = 1\).

Thus, we have

\[
\begin{align*}
\text{where the solutions may have many combinations under the above conditions. For example, when } (\mu_s, 1 - \mu_s)^T \in \Psi_1 \text{ and } (\mu_s, 1 - \mu_s)^T \in \Psi_2 \text{, if } \theta_s = 1 \text{ and } \theta_2 = 0, \text{ then } \eta_1 = 0, \eta_2 = 1, \eta_3 = 1, \eta_4 = 0.
\end{align*}
\]

In conclusion, \(\tilde{M}_i = L_i H_s (I_{2(\tau+1)} \otimes \tilde{M}_i) \Phi_{\tau+1}\) is solvable, \(s = 1, \ldots, l\).
Remark 3: The above Theorem 2 provides a sufficient and necessary condition for the solvability of the pinning feedback controllers for PBNs with time delays, which generalizes the results of [25]. In other words, if the transition matrix is a determined matrix, Theorem 2 is degenerated to be Proposition 3.2 of [25]. Once the system of equation (12) is solvable, then $L_s$ and $H_s$, $s = 1, 2, \ldots, l$, can be obtained according to the proof of Theorem 2.

The above results can be summed up as the Algorithm 2 to design pinning controllers for a PBN with time delays.

**Algorithm 2 Design Pinning Controllers**

**Input:** $q, M$

**Output:** $F_i, \varphi_i, i = 1, \ldots, l$

1: Using Algorithm 1 to change $M$ to the desired structure matrix $\tilde{M}$.
2: for $i = 1, \ldots, l$ do
3: Calculate $L_i, H_i$ from (12) by using Theorem 2.
4: end for
5: for $i = 1, \ldots, l$ do

**C. MINIMUM NUMBER OF PINNING NODES**

Based on the above discussion, the elements of set $\Xi(\delta^h_{2(r+1)})$ can be steered to the desired state $\delta^h_{2(r+1)}$. However, we want to get the minimum number nodes to be pinned. Suppose that $\Xi^e(\delta^h_{2(r+1)}) := \Delta_{2(r+1)} \setminus \Xi(\delta^h_{2(r+1)}) = \{\delta^i_{2(r+1)} \setminus \delta^h_{2(r+1)}, \ldots, \delta^j_{2(r+1)}\}$. Next, we will stabilize elements in $\Xi^e(\delta^h_{2(r+1)})$ by finding minimum pinning number nodes. Then, we can get a new matrix from $M$ as follows

$$C = \begin{bmatrix}
    \begin{bmatrix}
    a^1_{1} \\
    1 - a^1_{1}
    \end{bmatrix} & \begin{bmatrix}
    a^2_{1} \\
    1 - a^2_{1}
    \end{bmatrix} & \cdots & \begin{bmatrix}
    a^r_{1} \\
    1 - a^r_{1}
    \end{bmatrix} \\
    \begin{bmatrix}
    a^1_{2} \\
    1 - a^1_{2}
    \end{bmatrix} & \begin{bmatrix}
    a^2_{2} \\
    1 - a^2_{2}
    \end{bmatrix} & \cdots & \begin{bmatrix}
    a^r_{2} \\
    1 - a^r_{2}
    \end{bmatrix} \\
    \vdots & \vdots & \ddots & \vdots \\
    \begin{bmatrix}
    a^1_{l} \\
    1 - a^1_{l}
    \end{bmatrix} & \begin{bmatrix}
    a^2_{l} \\
    1 - a^2_{l}
    \end{bmatrix} & \cdots & \begin{bmatrix}
    a^r_{l} \\
    1 - a^r_{l}
    \end{bmatrix}
\end{bmatrix}
$$

where $Col_j(M) = \chi_{i=1}^{r+1}(a^j_i, 1 - a^j_i)^T$, $a^j_i \in [0, 1]$, $j = k_1, k_2, \ldots, k_l$, and $C \in R^{ij}_{2(r+1)}$. The following transformations are based on matrix $C$.

For the transition matrix $M = M_1 \ast \ldots \ast M_r$ of system (4), where $Col_j(M) = \chi_{i=1}^{r+1}(a^j_i, 1 - a^j_i)^T$, we define two matrix sets that $M^* = M_1^* \ast \cdots \ast M_r^*$ and $M^{**} = M_1^{**} \ast \cdots \ast M_r^{**}$, where $M_i^*, M_i^{**} \in P_{2\times(r+1)}$, $s = 1, \ldots, r+1$. Then, these matrix sets can be expressed as follows

$$\Theta[Col_i(C)] = \{M^*, M^{**}\},$$

where if $\delta^h_{2(r+1)} \in \Xi^e(\Delta^h_{2(r+1)})$, then $Col_j(M^*) = Col_j(M)$. If $\delta^j_{2(r+1)} \in \Xi^e(\Delta^h_{2(r+1)})$, then $Col_j(M^*) \in \Delta_2$.

$$\tilde{\Theta}[Col_i(C)] = \{M^{**}\},$$

where if $Col(M^*)$ belongs to two of $\Psi_1, \Psi_2, \Psi_4$, then $M^{**} = M^*$. If $Col(M^*) = \delta^j_{1}$, then $Col(M^*) \in \Psi_1$, and if $Col(M^*) \notin \Psi_1$, then $Col(M^*) = Col(M_j)$. $\Psi_1, \Psi_2, \Psi_4$.

**Lemma 4:** If $\chi_{j=1}^{r+1}(a^j_i, 1 - a^j_i) \ast \chi_{j=1}^{r+1}(a^j_i, 1 - a^j_i)$ can be steered to $\Xi^e(\delta^h_{2(r+1)})$, where $a^j_i \in (0, 1) \subseteq R$, then, $\chi_{j=1}^{r+1}(a^j_i, 1 - a^j_i) \ast \chi_{j=1}^{r+1}(a^j_i, 1 - a^j_i)$ can also be steered to $\Xi^e(\delta^h_{2(r+1)})$.

**Proof:** Since $\chi_{j=1}^{r+1}(a^j_i, 1 - a^j_i) \ast \chi_{j=1}^{r+1}(a^j_i, 1 - a^j_i)$ can be steered to $\Xi^e(\delta^h_{2(r+1)})$, then $\chi_{j=1}^{r+1}(a^j_i, 1 - a^j_i)$

Then, it holds that

$$\chi_{j=1}^{r+1}(a^j_i, 1 - a^j_i) \ast \chi_{j=1}^{r+1}(a^j_i, 1 - a^j_i) \subseteq \Xi^e(\delta^h_{2(r+1)}).$$

and

$$\chi_{j=1}^{r+1}(a^j_i, 1 - a^j_i) \ast \chi_{j=1}^{r+1}(a^j_i, 1 - a^j_i) \subseteq \Xi^e(\delta^h_{2(r+1)}).$$

**Theorem 3:** System (4) can be stabilized via only one pinning node if and only if there exist $j \in [1, \ldots, r+1]$ and a transition matrix $B$, such that $B \subseteq \tilde{\Theta}[Col_i(C)]$ where

$$\Xi^e(\delta^h_{2(r+1)}) = \Delta_{2(r+1)} \setminus \delta^h_{2(r+1)} \times \delta^h_{2(r+1)} \times \delta^h_{2(r+1)} = \delta^h_{2(r+1)}.$$

**Proof:** (Necessity)

Suppose system (4) can be stabilized by pinning one node $j$. According to Algorithm 1, we can get the set $\Delta = \{\{Col_i(M), j = k_1, k_2, \ldots, k_l\}$, the elements of which need to be changed. By changing the columns in set $\Delta$, system (4) is changed into $\chi_{x(t+1)} = \tilde{M}x(t) \ast \chi_{x(t)}$ and can realize globally stable.

Note that $M = M_1 \ast \ldots \ast M_r$ and $\tilde{M} = \tilde{M}_1 \ast \ldots \ast \tilde{M}_r$. For $i = k_1, k_2, \ldots, k_l$, it holds that $Col_i(M) = \chi_{m=1}^{r+1}(a^m_i, 1 - a^m_i)$. Hence, $Col_i(\tilde{M}) = \chi_{m=1}^{r+1}(a^m_i, 1 - a^m_i)$

$$\begin{bmatrix}
    \chi_{m=1}^{r+1}(a^m_i, 1 - a^m_i)
\end{bmatrix},$$

where $a^j_i \in [0, 1]$. 

---

VOLUME 8, 2020
Thus, it holds that $\tilde{M}_j$, as shown at the bottom of the next page.

For all $\alpha_i', i \in \{k_1, k_2, \ldots, k_l\}$, they can be classified into 7 parts as follows:

1. $\alpha_i' = 0$, $i = k_1, k_2, \ldots, k_l$,
2. $\alpha_i' = 1$, $i = k_1, k_2, \ldots, k_l$,
3. $\alpha_i' \notin \{0, 1\}$, $i = k_1, k_2, \ldots, k_l$,
4. some $\alpha_i' = 0$, some $\alpha_i' = 1$,
5. some $\alpha_i' = 0$, some $\alpha_i' \notin \{0, 1\}$,
6. some $\alpha_i' = 1$, some $\alpha_i' \notin \{0, 1\}$,
7. some $\alpha_i' = 0$, some $\alpha_i' = 1$, some $\alpha_i' \notin \{0, 1\}$.

Suppose there is a new matrix $B_j = B_j \in \mathcal{P}_{2r_{(t+1)}}$. The elements in $B_j$ not mentioned in the following discussion are the same as the corresponding elements in matrix $M_j$.

For (a), (b) and (c), let $B_j = \tilde{M}_j$.

For (d), if $i \in \{1, 2, \ldots, 2^{t_{(t+1)}}\} \setminus \{k_1, k_2, \ldots, k_l\}$ and $\alpha_i' \notin \{0, 1\}$, then let $\alpha_i' = 1$ in matrix $B_j$.

For (e), if $\alpha_i' \notin \{0, 1\}$, then let $\alpha_i' = 0$ in matrix $B_j$.

For (f), if $\alpha_i' \notin \{0, 1\}$, then let $\alpha_i' = 1$ in matrix $B_j$.

For (g), if $\alpha_i' \notin \{0, 1\}$, then let $\alpha_i' = 1$ in matrix $B_j$.

Thus, according to Lemma 4, $B = \tilde{M}_1 \ast \ldots \ast B_j \ast \ldots \ast \tilde{M}_t$ can steer all initial states to the desire states $\delta^h_{2^t}$. It also holds that $B \subseteq \tilde{\Theta}[Col_j(C)]$.

(Sufficiency)

Let the transition matrix $B \subseteq \tilde{\Theta}[Col_j(C)]$ and $\Xi(\delta^h_{2^{(t+1)}}) = \Delta_{2^{(t+1)}}$, where $B = M_1 \ast \ldots \ast B_j \ast \ldots \ast M_t$. Then, $Col_j(B_i)$ belongs to two of $\Psi_1, \Psi_3, \Psi_4$ at most. Thus, there exists a state feedback control $u(t) = Hx(t) \ldots x(t-\tau)$ satisfying $B = H(I_{2^{(t+1)}} \otimes M_t)\Phi_r$. Therefore, the one pinned node is $j$ and the pinning controller with delays can be solved from (12) by using Theorem 2.

Next, the above results can be further generalized as follows:

$$\Theta[Col_{i_1, i_2, \ldots, i_r}(C)] = \{M^*\},$$

where the matrix $M^*$ satisfies the following conditions: if $\delta^h_{2^{(t+1)}} \in \Xi(\Delta^h_{2^{(t+1)}})$, then $Col_j(M^*) = Col_j(M)$, and if $\delta^h_{2^{(t+1)}} \notin \Xi(\Delta^h_{2^{(t+1)}})$, then $Col_j(M^* \ast M^* \ast \ldots \ast M^*) = \Delta_{2^t}$, $j = 1, 2, \ldots, r(t+1)$.

$$\tilde{\Theta}[Col_{i_1, i_2, \ldots, i_r}(C)] = \{M^{**}\},$$

where the matrix $M^{**}$ satisfies the conditions: if $Col_j(M^*) \in \Theta[Col_{i_1, i_2, \ldots, i_r}(C)]$, then $M^{**} = M^*$, and when $i \in \{i_1, i_2, \ldots, i_r\}$ and $j \in \{1, 2, \ldots, 2^{t_{(t+1)}}\} \setminus \{k_1, k_2, \ldots, k_l\}$,

$$\tilde{M}_j = \begin{bmatrix}
\alpha_j^1 & \cdots & \alpha_j^k & \cdots & \alpha_j^l & \cdots & \alpha_j^l \\
1 - \alpha_j^1 & \cdots & 1 - \alpha_j^k & \cdots & 1 - \alpha_j^l & \cdots & 1 - \alpha_j^l \\
\end{bmatrix}_{k \times l}.$$

**Algorithm 3** Calculate the Minimal Number of Pinning Controllers

**Input:** $q, \tilde{M}, \tilde{M}$

**Output:** $\Sigma(N, \Omega)$

1: Initialize $P = \emptyset$
2: for $i = 1, 2, \ldots, r(t+1)$ do
3: \hspace{1em} Calculate $\tilde{\Theta}[Col_j(C)]$ for the elements in this set as $M^1_j, M^2_j, \ldots, M^k_j$
4: \hspace{1em} for $j = 1, 2, \ldots, 2^r$ do
5: \hspace{2em} if $\Xi(\delta^h_{2^{(t+1)}}) = \Delta_{2^{(t+1)}}$ when matrix $M^l_j$ is transition matrix then
6: \hspace{3em} return $\Sigma(1, [i])$
7: \hspace{1em} end if
8: \hspace{1em} end for
9: \hspace{1em} end for
10: for $t = 2, 3, \ldots, r(t+1)$ do
11: \hspace{1em} choose $t$ nodes: $i_1, i_2, \ldots, i_t$ as a set $\lambda_k = \{i_1, i_2, \ldots, i_t\}, k = 1, 2, 3, \ldots, C^t_{r(t+1)}$
12: \hspace{1em} for $j = 1, 2, \ldots, C^t_{r(t+1)} = \frac{r(t+1)!}{t!(r(t+1)-t)!}$ do
13: \hspace{2em} Calculate $\tilde{\Theta}[Col_{i_1, i_2, \ldots, i_r}(C)]$ for the elements in this set as $M^1_j, M^2_j, \ldots, M^k_j$
14: \hspace{2em} for $l = 1, 2, \ldots, 2^{r-1}$ do
15: \hspace{3em} if $\Xi(\delta^h_{2^{(t+1)}}) = \Delta_{2^{(t+1)}}$ when matrix $M^l_j$ is transition matrix then
16: \hspace{4em} return $\Sigma(t, \{i_1, i_2, \ldots, i_t\})$
17: \hspace{3em} end if
18: \hspace{3em} end for
19: \hspace{3em} end for
20: end for

Then, the above theorem can be further generalized as follows:

**Theorem 4:** System (4) achieves stability via $t$ pinning nodes if and only if there exists $i_1, \ldots, i_t \in \{1, \ldots, r(t+1)\}$ and a transition matrix $\tilde{M}$, such that $\tilde{M} \in \tilde{\Theta}[Col_{i_1, i_2, \ldots, i_t}(A)]$.

where $\Xi(\delta^h_{2^{(t+1)}}) = \Delta_{2^{(t+1)}}$ and $\delta^h_{2^{(t+1)}} \times \delta^h_{2^{(t+1)}} \times \cdots \times \delta^h_{2^{(t+1)}} = \delta^h_{2^{(t+1)}}$.

**Proof:** Using Algorithm 1, the structure matrix $M$ can be changed to $\tilde{M}$, and these matrices can be decomposed to $M = \tilde{M}_1 \tilde{M}_2 \ldots \tilde{M}_r$ and $M = M_1 M_2 \ldots M_r$. Comparing $M$ with $\tilde{M}$, we can know that $\tilde{M}_j$ and $M_j$ are different for $j = s_1, s_2, \ldots, s_t$. For $j \in \{s_1, s_2, \ldots, s_t\}$, $\tilde{M}_j$ are changed by using Theorem 3. The rest of proof is similar to Theorem 3, and it is omitted here.

It holds that

$$Col_j(M^{**}) = \begin{cases}
\delta^1_{2^t}, & \text{if } Col_j(M^*) \in \Psi_1, \\
Col_j(M^*), & \text{if } Col_j(M^*) \notin \Psi_1.
\end{cases}$$

From Theorem 3 and 4, the existence of minimum pinning nodes are discussed, and the necessary and sufficient conditions are obtained about exact number of pinning controllers. Next, the following Algorithm 3 is given to stabilize system (4) to the objective state $\delta_5^2$ via minimum pinning controllers, which is based on these two theorems, and the minimum number of pinning controllers is solved by traversal.

In the following Algorithm 3, we denote the set $\Sigma(N, \Omega)$, where $N$ stands for the minimum number and $\Omega$ stands for the set of pinning controllers. And $t$ of $i_t$ stands for the number of pinning controllers. Since there are finite nodes totally, if $t$ adds to $r$, then the corresponding results will be returned.

**IV. EXAMPLES**

**Example 1:** Consider the following PBNs with time delays

$$
\begin{align*}
\rho_1(t + 1) &= f_1(\rho_1(t), \rho_2(t), \rho_1(t - 1), \rho_2(t - 1)), \\
\rho_2(t + 1) &= f_2(\rho_1(t), \rho_2(t), \rho_1(t - 1), \rho_2(t - 1)),
\end{align*}
$$

where $f_1 \in \{f_1^1, f_1^2\}$, $f_2 \in \{f_2^1, f_2^2\}$, and $P(f_1 = f_1^1) = \frac{1}{2}$, $P(f_1 = f_1^2) = \frac{1}{2}$, $P(f_2 = f_2^1) = \frac{2}{3}$, $P(f_2 = f_2^2) = \frac{1}{3}$.

These boolean functions are as follows

$$
\begin{align*}
f_1^1 &= \rho_1(t) \lor \rho_1(t - 1) \land \rho_2(t - 1), \\
f_1^2 &= \rho_2(t) \lor \rho_1(t - 1) \land \rho_2(t - 1), \\
f_2^1 &= \rho_1(t) \lor \rho_1(t - 1) \lor \rho_2(t - 1), \\
f_2^2 &= \rho_2(t) \lor \rho_1(t - 1) \lor \rho_2(t - 1),
\end{align*}
$$

Then, we can obtain

$$
M_1^1 = M_\land M_\lor (I_2 \otimes 1_2^T)
= \delta_{16}[1, 2, 1, 2, 1, 2, 1, 2, 2, 1, 2, 2, 1, 2, 2, 2, 2, 2],
$$

$$
M_1^2 = M_\land M_\lor (I_2 \otimes 1_2^T)
= \delta_{16}[1, 2, 1, 2, 1, 2, 2, 1, 2, 1, 2, 2, 1, 2, 2, 2, 2, 2].
$$

Hence, we have $\tilde{M}_1$, $\tilde{M}_2$, and $M$, as shown at the bottom of the page.

Next, we use Algorithm 1 to design the pinning feedback controllers to steer the PBNs (23) to the objective state $\delta_4^3$ in probability 1, and $\delta_4^3 \ll \delta_4^3 = \delta_1^{16}$.

Firstly, since $Col_{11}(M) = (\frac{1}{8}, \frac{1}{6}, \frac{1}{8}, \frac{1}{6})_T$, we change $Col_{11}(M)$ to $\delta_4^3$.

Secondly, calculate $\Xi(\delta_{16}^{11}) = \cup_{i=1}^{16} \Xi(\delta_{16}^{i})$. We find that

$$
\Xi(\delta_{16}^{11}) = \{\delta_{16}^{2}, \delta_{16}^{4}, \delta_{16}^{6}, \delta_{16}^{8}, \delta_{16}^{10}, \delta_{16}^{12}, \delta_{16}^{14}, \delta_{16}^{18}, \delta_{16}^{20}\}
$$

and

$$
\Xi(\delta_{16}^{21}) = \{\delta_{16}^{4}, \delta_{16}^{6}, \delta_{16}^{8}, \delta_{16}^{10}, \delta_{16}^{12}, \delta_{16}^{14}, \delta_{16}^{16}, \delta_{16}^{18}, \delta_{16}^{20}\}
$$

Hence, it holds that

$$
\Xi(\delta_{16}^{11}) = \{\delta_{16}^{2}, \delta_{16}^{4}, \delta_{16}^{6}, \delta_{16}^{8}, \delta_{16}^{10}, \delta_{16}^{12}, \delta_{16}^{14}, \delta_{16}^{16}, \delta_{16}^{18}, \delta_{16}^{20}\}
$$

Thirdly, change the 7th, 8th, 12th, 16th columns to $\delta_4^3$. Then, $M$ is changed into $\tilde{M}$ as follows

Thus, we have $\tilde{M}$, $\tilde{M}_1$, and $\tilde{M}_2$ as shown at the top of the next page.

Since $M_1 \neq \tilde{M}$ and $\tilde{M}_2 \neq \tilde{M}_2$, there exist $F_1$ and $F_2$ such that $\rho_1(t + 1) = F_1(u_1(t), f_1)$ and $\rho_2(t + 1) = F_2(u_2(t), f_2)$. 

\[
\tilde{M}_1 = \frac{1}{2}M_1^1 + \frac{1}{2}M_1^2
= \begin{bmatrix}
1 & 0 & 1 & 0 & 1 & 0 & \frac{1}{2} & 0 & 1 & 0 & \frac{1}{2} & 0 & 1 & 0 & 0 & 0 \\
0 & 1 & 0 & 1 & 0 & 1 & \frac{1}{2} & 1 & 0 & 1 & \frac{1}{2} & 1 & 0 & 1 & 1 & 1
\end{bmatrix},
\]

\[
\tilde{M}_2 = \frac{2}{3}M_1^1 + \frac{1}{3}M_1^2
= \begin{bmatrix}
0 & 1 & 0 & 1 & 0 & 1 & \frac{1}{3} & 0 & 1 & \frac{3}{3} & 0 & 1 & 1 & 0 \\
1 & 0 & 1 & 0 & 1 & 0 & \frac{2}{3} & 1 & 0 & \frac{1}{3} & 2 & 1 & 0 & 0 & 1
\end{bmatrix},
\]

\[
M = M_1 \cdot \tilde{M}_2
= \begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0 & \frac{1}{6} & 0 & 0 & 0 & \frac{1}{3} & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 1 & 0 & 1 & 0 & \frac{1}{3} & 0 & 1 & \frac{3}{3} & 0 & 1 & 0 & 0 & 0 \\
0 & 1 & 0 & 1 & 0 & 1 & \frac{2}{6} & 2 & 0 & \frac{1}{3} & \frac{1}{3} & 1 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & \frac{1}{3} & 0 & \frac{1}{6} & 3 & 0 & 0 & 0 & 0 & 1
\end{bmatrix},
\]
\[ \hat{M} = \hat{M}_1 * \hat{M}_2 \]
\[
\begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 1 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1
\end{bmatrix}
\]

Then, according to the proof of Theorem 2, \( L_1 = \delta_2[2, 2, 2, 2] \) and \( L_2 = \delta_2[1, 1, 1, 2] \). Hence, the logical relationship between \( f_j \) and \( u_j \) for \( j = 1, 2 \) are \( F_1 = u_1 * f_1 \) and \( F_2 = u_2 * f_2 \). Furthermore, \( H_1 = \delta_2[2, 2, 2, 2, 2, 1, 1, 2, 2, 2, 2, 2, 2] \) and \( H_2 = \delta_2[2, 2, 2, 2, 2, 1, 1, 2, 2, 1, 2, 2, 1, 2] \) can be obtained. Thus, the feedback controllers can be designed as follows

\[
\begin{align*}
\mu_1 &= \{ \rho_1(t) \land (\neg \rho_2(t)) \land (\neg \rho_1(t - 1)) \land \rho_2(t - 1) \} \lor \\
&\{ \neg \rho_1(t) \land \rho_2(t) \land (\neg \rho_1(t - 1)) \land \rho_2(t - 1) \} \\
\mu_2 &= \{ \rho_1(t) \land (\neg \rho_2(t)) \land \rho_2(t - 1) \} \lor \{ \neg \rho_1(t) \land (\rho_2(t) \land \neg \rho_2(t - 1)) \lor (\neg \rho_1(t - 1)) \land (\neg \rho_2(t - 1)) \})
\end{align*}
\]
(22)

Then, we can use Algorithm 3 to calculate the minimum number of pinning controllers. It can be found that the minimum number of pinning controllers is 2 for (21).

V. CONCLUSION

In this article, for PBNs with time delays, the stabilization issue has been discussed. With the help of STP, the transition matrix of a PBN with time delays can be obtained, and the model is converted into a discrete-time linear system. Then, the necessary and sufficient conditions in the form of the algebraic expression for the pinning feedback controllers’ existence and solvability are given. Moreover, the existence of minimum pinning nodes is discussed and the corresponding algorithm is designed. In the future, we will extend the results of this article to PBNs with more communication constraints, such as impulsive effects, stochastic perturbations, etc.

KAIBO SHI (Member, IEEE) received the Ph.D. degree from the School of Automation Engineering, University of Electronic Science and Technology of China. From September 2014 to September 2015, he was a Visiting Scholar with the Department of Applied Mathematics, University of Waterloo, Waterloo, ON, Canada. He was a Research Assistant with the Department of Computer and Information Science, Faculty of Science and Technology, University of Macau, Taipa, from May 2016 to June 2016 and from January 2017 to October 2017. He was also a Visiting Scholar with the Department of Electrical Engineering, Yeungnam University, Gyeongsan, South Korea, from December 2019 to January 2020. He is currently a Professor with the School of Information Sciences and Engineering, Chengdu University. His current research interests include stability theorem, robust control, sampled-data control systems, networked control systems, Lurie chaotic systems, stochastic systems, and neural networks. He is the author or coauthor of over 60 research articles. He is a very Active Reviewer of many international journals.

JIANQUAN LU (Senior Member, IEEE) received the B.S. degree in mathematics from Zhejiang Normal University, Zhejiang, China, in 2003, the M.S. degree in mathematics from Southeast University, Nanjing, China, in 2006, and the Ph.D. degree in applied mathematics from the City University of Hong Kong, Hong Kong, in 2009. From 2010 to 2012, he was an Alexander von Humboldt Research Fellow of PIK, Germany. He is currently a Professor with the School of Mathematics, Southeast University. His current research interests include collective behavior in complex dynamical networks and multiagent systems, logical networks, and hybrid systems. He has published over 90 articles in refereed international journals. He was a recipient of the Alexander von Humboldt Fellowship, in 2010, the Program for New Century Excellent Talents in University by the Ministry of Education, China, in 2010, the Second Award of Jiangsu Provincial Progress in Science and Technology as the First Project Member, in 2016, and the First Award of Jiangsu Provincial Progress in Science and Technology as the Second Project Member, in 2010. He was named a Highly Cited Researcher by Clarivate Analytics, in 2018. He was elected as a Most Cited Chinese Researchers by Elsevier, from 2014 to 2018. He is an Associate Editor of Neural Processing Letters (Springer), the Journal of the Franklin Institute (Elsevier), and Neural Computing and Applications (Springer) and a Guest Editor of Science China Information Sciences, Mathematics and Computers in Simulation (Elsevier), and IET Control Theory & Applications.

PENGWEI LIU is currently pursuing the bachelor’s degree with the School of Mathematics, Hefei University of Technology.

LULU LI received the B.S. degree in mathematics and applied mathematics from Anhui Normal University, Wuhu, China, in 2007, the M.S. degree in mathematics from Southeast University, Nanjing, China, in 2010, and the Ph.D. degree from the City University of Hong Kong, Hong Kong, in 2013.

He is currently an Associate Professor with the School of Mathematics, Hefei University of Technology, Hefei, China. His current research interests include nonlinear systems, collective behavior in complex dynamical networks, and multiagent systems.
