ABSTRACT. We determine the critical groups of the generalized de Bruijn graphs $DB(n, d)$ and generalized Kautz graphs $Kautz(n, d)$, thus extending and completing earlier results for the classical de Bruijn and Kautz graphs. Moreover, for a prime $p$ the critical groups of $DB(n, p)$ are shown to be in close correspondence with groups of $n \times n$ circulant matrices over $F_p$, which explains numerical data in [11], and suggests the possibility to construct normal bases in $F_{p^n}$ from spanning trees in $DB(n, p)$.

1. INTRODUCTION

The critical group of a directed graph $G$ is an abelian group obtained from the Laplacian matrix $\Delta$ of $G$; it determines and is determined by the Smith Normal Form (SNF) of $\Delta$. (For precise definitions of these and other terms, we refer to the next section.) The sandpile group $S(G, v)$ of $G$ at a vertex $v$ is an abelian group obtained from the reduced Laplacian $\Delta_v$ of $G$; its order is equal to the complexity $\kappa(G)$ of $G$, the number of directed trees rooted at $v$, a fact that is related to the Matrix Tree Theorem, see for example [8] and its references. If $G$ is Eulerian, then $S(G, v)$ does not depend on $v$, and is then simply written as $S(G)$; in that case, it is equal to the critical group of $G$. The critical group has been studied in other contexts under several other names, such as group of components, Picard or Jacobian group, and Smith group. For more details and background, see, e.g., [6].

Critical groups have been determined for a large number of graph families. For some examples, see the references in [11]. Here, we determine the critical group of the generalized de Bruijn graphs $DB(n, d)$ and generalized Kautz graphs $Kautz(n, d)$, thus extending and completing the results from [8] for the binary de Bruijn graphs $DB(2^d, 2)$ and Kautz graphs (with $p$ prime) $Kautz((p - 1)p^{d-1}, p)$, and [3] for the classical de Bruijn graphs $DB(d^d, d)$ and Kautz graphs $Kautz((d - 1)d^{d-1}, d)$. Unlike the classical case, the generalized versions are not necessarily iterated line graphs, so to obtain their critical groups, different techniques have to be applied.

E-mail address: {sweehong, henk.hollmann, dima}@ntu.edu.sg.
Our original motivation for studying these groups stems from their relations to some algebraic objects, such as the groups $C(n,p)$ of invertible $n \times n$-circulant matrices over $\mathbb{F}_p$ (mysterious numerical coincidences were noted in the OIES entry A027362 \cite{11} by the third author, computed with the help of \cite{15,12}), and normal bases (cf. e.g. \cite{9}) of the finite fields $\mathbb{F}_{p^n}$. The latter were noted to be closely related to circulant matrices and to necklaces by Reutenauer \cite{13 Sect. 7.6.2}, see also \cite{5}, and the related numeric data collected in \cite{2}. In particular, we show that $C(n,p)/(\mathbb{Z}_{p-1} \times \mathbb{Z}_n)$ is isomorphic to the critical group of $\text{DB}(n,p)$. Although we were not able to construct an explicit bijection between the former and the latter, we could speculate that potentially one might be able to design a new deterministic way to construct normal bases of $\mathbb{F}_{p^n}$.

2. Preliminaries

Let $M$ be an $m \times n$ integer matrix of rank $r$. For a ring $F$, we write $R_F(M) = M^\top F^n$, the $F$-module generated by the rows of $M$. The Smith group \cite{14} of $M$ is defined as $\Gamma(M) = \mathbb{Z}^n/R_{\mathbb{Z}}(M)$. The submodule $\overline{\Gamma}(M) = \mathbb{Z}^n/R_{Q}(M) \cap \mathbb{Z}^n$ of $\Gamma(M)$ is a finite abelian group called the finite part of $\Gamma(M)$. Indeed, if $M$ has rank $r$, then $\overline{\Gamma}(M) = \mathbb{Z}^{n-r} \oplus \Gamma(M)$ with $\Gamma(M) = \oplus_{i=1}^{r} \mathbb{Z}_{d_i}$, where $d_1, \ldots, d_r$ are the nonzero invariant factors of $M$, so that $d_i | d_{i+1}$ for $i = 1, \ldots, r - 1$. For invariant factors and the Smith Normal Form, we refer to \cite{10}. See \cite{14} for further details and proofs.

Let $G = (V, E)$ be a directed graph on $n = |V|$ vertices. The indegree $d^-(v)$ and outdegree $d^+(v)$ is the number of edges ending or starting in $v \in V$, respectively. The adjacency matrix of $G$ is the $n \times n$ matrix $A = (A_{v,w})$, with rows and columns indexed by $V$, where $A_{v,w}$ is the number of edges from $v$ to $w$. The Laplacian of $G$ is the matrix $\Delta = D - A$, where $D$ is diagonal with $D_{v,v} = d^+_v$. The critical group $K(G)$ of $G$ is the finite part of the Smith group of the Laplacian $\Delta$ of $G$. The sandpile group $S(G, v)$ of $G$ at $v \in V$ is the finite part of the Smith group of the $(n-1) \times (n-1)$ reduced Laplacian $\Delta_v$, obtained from $\Delta$ by deleting the row and the column of $\Delta$ indexed by $v$. Note that by the Matrix Tree Theorem for directed graphs, the order of $S(G, v)$ equals the number of directed spanning trees rooted at $v$. $G$ is called Eulerian if $d^+(v) = d^-(v)$ for every $v \in V$. In that case, $S(G, v)$ does not depend on $v$ and is equal to the critical group $S(G)$ of $G$. For more details on sandpile groups and critical groups of directed graphs, we refer for example to \cite{6} or \cite{16}.

2.1. Generalized de Bruijn and Kautz graphs. Generalized de Bruijn graphs and generalized Kautz graphs \cite{4} are known to have a relatively small diameter and attractive connectivity properties, and have been studied intensively due to their applications in interconnection networks. The generalized Kautz graphs were first investigated in \cite{7}, and are also known as Imase-Itoh digraphs. Both classes of graphs are Eulerian.

We will determine the critical group, or, equivalently, the sandpile group, of a generalized de Bruijn or Kautz graph on $n$ vertices by embedding this group
Corollary 2.2. If \( a \in \Sigma(n, d) \) with \( a = \sum_{v} a_v e_v \), then \( a \in S(n, d) \) if and only if \( \sum_{v} va_v \equiv 0 \pmod{n} \).

Corollary 2.2. We have \( \Sigma(n, d) / S(n, d) = \mathbb{Z}_n \) and so \( |\Sigma(n, d)| = n|S(n, d)| \).
The above descriptions of the sandpile group $S(n, d)$ and sand dune group $\Sigma(n, d)$, and the embedding of $S(n, d)$ as a subgroup of $\Sigma(n, d)$ are very suitable for the determination of these groups. In the process, repeatedly information is required about the order of various group elements. The following two results provide that information.

**Lemma 2.3.** Let $a = \sum_v a_v e_v \in \Sigma(n, d)$. Then the order of $a$ in $\Sigma(n, d)$ is the smallest positive integer $m$ for which $ma_v \in \mathbb{Z}$ for each $v$.

We say that $v \in \mathbb{Z}_n$ has $d$-type $(f, e)$ in $\mathbb{Z}_n$ if $v, dv, \ldots, d^n v$ all distinct, with $d^n v = d^f v$. Now, by expressing $e_v$ in terms of the $e_v$, we can determine the order of $e_v$. The result is as follows.

**Lemma 2.4.** Supposing $v$ has $d$-type $(f, e)$, then $e_v = \sum_{i=0}^{f-1} d^{-i-1} e_{dv} + \sum_{j=0}^{e-1} d^{-j-f} (d^e - 1)^{-1} e_{d^{j+f}v}$ in $\mathbb{Z}_n$, and hence $e_v$ has order $d^f (d^e - 1)$ in $\Sigma(n, d)$.

### 2.2. Invertible circulant matrices

Let $Q_n$ be the $n \times n$ permutation matrix over a field $F$ corresponding to the cyclic permutation $(1, 2, \ldots, n)$. An $n \times n$ circulant matrix over $F$ is a matrix that can be written as $a_1 Q_n + a_2 Q_n^2 + \ldots + a_n Q_n^n$ with $a_i \in F$ for $1 \leq i \leq n$. All the invertible circulant matrices form a commutative group (w.r.t. matrix multiplication), namely, the centralizer of $Q_n$ in $GL_n(F)$. In the case $F = \mathbb{F}_p$ we consider here we denote this commutative group by $C(n, p)$. Note that $C(n, p)$ contains a subgroup isomorphic to $\mathbb{Z}_{p-1} \oplus \mathbb{Z}_n$, namely the direct product of the group of scalar matrices $\mathbb{F}_p^* I := \{ \lambda I \mid \lambda \in \mathbb{F}_p^* \}$ and the cyclic subgroup generated by $Q_n$. Each circulant matrix has all-ones vector $1 := (1, \ldots, 1)^\top$ as an eigenvector. Thus $C'(n, p) := \{ g \in C(n, p) \mid g 1 = 1 \}$ is a subgroup of $C(n, p)$, and we have the following formula.

\begin{equation}
C(n, p) = C'(n, p) \times F_p^* I.
\end{equation}

### 3. Main results

Let $n, d > 0$ be fixed integers. The description of the sandpile group $S(n, d)$ and the sand-dune group $\Sigma(n, d)$ of the generalized the Bruin graph DB$(n, d)$ involves a sequence of numbers defined as follows. Put $n_0 = n$, and for $i = 1, 2, \ldots, $ define $g_i = \gcd(n_i, d)$ and $n_{i+1} = n_i / g_i$. We have $n_0 > \cdots > n_k = n_{k+1}$, where $k$ is the smallest integer for which $g_k = 1$. We will refer to the sequence $n_0 > \cdots > n_k = n_{k+1}$ as the $d$-sequence of $n$. In what follows, we will write $m = n_k$ and $g = g_0 \cdots g_{k-1}$. Note that $n = gm$ with $\gcd(m, d) = 1$.

Since $\gcd(m, d) = 1$, the map $x \to dx$ partitions $\mathbb{Z}_m$ into orbits of the form $O(v) = (v, dv, \ldots, d^{\gcd(v, m)-1}v)$. We will refer to $o(v) = |O(v)|$ as the order of $v$.

For every prime $p|m$, we define $\pi_p(m)$ to be the largest power of $p$ dividing $m$. Let $V$ be a complete set of representatives of the orbits $O(v)$ different from $\{0\}$, where we ensure that for every divisor $p$ of $m$, all integers of the form $m/p^j$ are contained in $V$. 

Theorem 3.1. With the above definitions and notation, we have that

\[ \Sigma(n, d) = \bigoplus_{i=0}^{k-1} \mathbb{Z}_{d^{i+1}}^{n_i-2n_{i+1}+n_{i+2}} + \bigoplus_{v \in V} \mathbb{Z}_{d^{v}(v) - 1} \]  

and

\[ S(n, d) = \bigoplus_{i=0}^{k-1} \mathbb{Z}_{d^{i+1}/g_i}^{n_i-2n_{i+1}+n_{i+2}-1} + \bigoplus_{v \in V} \mathbb{Z}_{(d^{v}(v) - 1)/c(v)} \]

where \( c(v) = 1 \) except in the following cases. For any \( p|m \),

\[ c(m/\pi_p(m)) = \begin{cases} \pi_p(m), & \text{if } p \neq 2 \text{ or } d \equiv 1 \mod 4 \text{ or } 4 | m; \\ \pi_2(m)/2, & \text{if } p = 2 \text{ and } d \equiv 3 \mod 4 \text{ and } 4|m, \end{cases} \]

and if \( 4|m \) and \( d \equiv 3 \mod 4 \), then \( c(m/2) = 2 \).

For the generalized Kautz graph, a similar result holds. For \( v \in \mathbb{Z}_m \), we let \( O'(v) \) denote the orbit of \( v \) under the map \( x \mapsto -dv \), and we define \( o'(v) = |O'(v)| \). Now take \( V' \) to be a complete set of representatives of the orbits on \( \mathbb{Z}_m \). Finally, define \( c'(v) \) similar to \( c(v) \), except that now \( d \) is replaced by \(-d\) (so the special case now involves \( d \equiv 1 \mod 4 \)). Then we have the following.

Theorem 3.2. The sandpile group \( S_{Kautz}(n, d) \) of the generalized Kautz graph Kautz\((n, d)\) is obtained from \( S(n, d) \) by replacing \( V \) by \( V' \), \( o(v) \) by \( o'(v) \), and \( c(v) \) by \( c'(v) \) in (6).
\( \tilde{e}_v = e_v - \sum_{p|m} \lambda_p(v)e_{\pi_p(v)m/\pi_p(m)}, \) where the numbers \( \lambda_p(v) \) are chosen such that \( \tilde{e}_v \in S(m, d) \), or by a suitable multiple of \( e_v \), in some exceptional cases (these are cases where \( c(v) > 1 \)). It turns out that this is indeed possible, and in this way the proof of Theorem 3.1 can be completed.

Finally, with the notation from Subsect. 2.2 we have the following isomorphisms, connecting critical groups and circulant matrices.

**Theorem 3.3.** Let \( d \) be a prime. Then

\[
S(n, d) \cong C'(n, d)/Q_n, \quad \text{and} \quad \Sigma(n, d) \cong C'(n, d).
\]

The proof of Theorem 3.3 is by reducing to the case \( \gcd(n, p) = 1 \) by an explicit construction, and then by diagonalizing \( C(n, p) \) over an appropriate extension of \( \mathbb{F}_p \). Essentially, as soon as \( \gcd(n, p) = 1 \), one can read off a decomposition of \( C(n, p) \) into cyclic factors from the irreducible factors of the polynomial \( x^n - 1 \) over \( \mathbb{F}_p \).
