Conclusion. A rapid test of less than 2 h can readily identify MSSA isolates exhibiting the CIE. For isolates carrying type A BlaZ, which is highly associated with the CIE, the test had a sensitivity and specificity of 100%. Rapid identification of MSSA with the CIE may have important therapeutic consequences in deep-seated infections.

2177. The Impact of the BioFire® FilmArray Gastrointestinal Syndromic Panel on the Management of Infectious Gastroenteritis due to Diarrheagenic E. coli Strains in a Large Community Hospital

Christopher Bryan. Jackson, PharmD Candidate1; Brenda Astorga, PharmD Candidate2; Gerald Gavreys, PharmD, BCPS, BCIDP3; Kelly R. Revelles, PharmD, PhD3; Grace Lee, PharmD, PhD, BCPS4; UT Austin College of Pharmacy, The University of Texas Health Science Center, Austin, Texas; Methodist Hospital & Methodist Children's Hospital, San Antonio, Texas; The University of Texas at Austin, San Antonio, Texas; College of Pharmacy, Pharmacotherapy Education and Research Center, School of Medicine, The University of Texas at Austin, UT Health San Antonio, San Antonio, Texas

Session: 243. Bacterial Diagnostics
Saturday, October 5, 2019: 12:15 PM

Background. PCR-based rapid diagnostic tests (RDTs) provide rapid and accurate infectious gastroenteritis (IGE) etiologies within hours. However, there are limited data evaluating the impact of these panels on the appropriate management for diarrheagenic E. coli strains (DECS). This study evaluated the impact of the BioFire® FilmArray GI panel on the appropriate antimicrobial management of DECS.

Methods. A retrospective analysis was conducted at a large community hospital in San Antonio, TX. Patients with a positive infectious diarrhea diagnostic panel (IDDP) for DECS from October 1, 2016 through September 30, 2018 and admitted for 248 hours were included. Patients were excluded if they had a positive IDDP for multiple DECs. An algorithm based on all available literature was used to classify appropriate management of DECS, which included patients having prolonged diarrhea (≥27 days), immunocompromised hosts (ICHs), or the presence of systemic symptoms. Antimicrobial therapy changes based on IDDP results, presence of an ID consult, and incidence of hemolytic uremic syndrome (HUS) were evaluated.

Results. A total of 374 patients were included for analysis. Overall, the IDDP resulted in 84 antimicrobial changes including initiation of appropriate antibiotics (n = 48) and de-escalation/discontinuation (n = 22), primarily in special populations, such as ICHs. The IDDP results led to appropriate therapy optimization in 63%, 17%, 16%, and 9% of enteroinvasive E. coli (EIEC), enteraggregative E. coli (EAEC), enteropathogenic E. coli (EPEC), and enterotoxigenic E. coli (ETEC) cases, respectively. In contrast, 81% of Shiga toxin-producing E. coli (STEC) cases were inappropriately managed with antibiotics, and 33% developed HUS. Only 14% of all DECS cases generated an ID consult.

Conclusion. Of note, this study found that the IDDP did not lead to a change in the management of most pathotypes. However, it was associated with positive changes in the management of DECS in specific patients, particularly ICHs. RDTs assist providers in the timely identification and treatment of IGE pathogens, but both antimicrobial and diagnostic stewardship remain critical for the optimal management of DECS.

2178. Sensitivity of Blood Cultures in Detection of Bacteremia in Febrile Neutropenia

Vanisha Patel, Jose Amadeo A. Ferralino, III, MD, MPH; Randall Hayden, MD; Randall Hayden, MD; Aditya H. Gaur, MD; St. Jude Children’s Research Hospital, Memphis, Tennessee

Session: 243. Bacterial Diagnostics
Saturday, October 5, 2019: 12:15 PM

Background. Febrile neutropenia (FN) secondary to bacteremia is a treatable complication of chemotherapy that increases mortality if not promptly recognized and managed.

Methods. The sensitivity of blood cultures collected in pediatric oncology patients with FN was assessed and stratified based on the day of FN episode, culture media, and the use of blood culture double draw at a single US community children’s hospital. Blood cultures were collected between November 2013 and 2018. Paired aerobic and anaerobic media bottles were inoculated with each culture draw using a weight-based volume of blood; anaerobic cultures were included with initial cultures starting in September of 2017.

Results. In a retrospective analysis of 10,596 patients, a total of 3,039 episodes of FN were identified. Of the FN episodes, 17.7% had at least one positive blood culture; 84.5%, 1.3%, 0.9% and 13.3% of positive cultures were collected on day 0, day 1, day 2 and day 3 of a febrile episode. Among the positive day 0 cultures, the median time to detection of an organism was 14.1 hours. Host characteristics of blood culture-positive FN episodes are summarized in Table 1.

Conclusion. In summary, the study findings have important clinical implications such as emphasizing the value of day 0 cultures and highlighting the importance of routinely collecting blood cultures in more than one media type. Despite an optimized blood culture approach, less than a fifth of FN episodes had a blood culture-based diagnosis.

Table 1: Host characteristics of those with blood culture positive FN episodes.

| Overall (n=537) | Sex (%) | Race (%) | Number of days culture was collected | Duration of Episode (days) | Admission Status (%) | Service at Admission (%) |
|----------------|---------|----------|-------------------------------------|---------------------------|----------------------|-------------------------|
|               | Female  |          | Mean (SD)                           | Median (IQR)              | Male                 | Hispanic                |
|               |         |          | 245 (45.6)                          | 9.14 (6.05)               | 9.00 (4.00, 14.00)   | 140 (26.1)              |

2179. Detection of Group A Streptococcus in the Saliva of Children Presenting With Pharyngitis Using the cobas®/LIAT® PCR System

Gregory P. DeMuri, MD; Ellen R. Wals, MD; School of Medicine and Public Health, University of Wisconsin, Madison, Wisconsin

Session: 243. Bacterial Diagnostics
Saturday, October 5, 2019: 12:15 PM

Background. CLIA waived polymerase chain reaction (PCR) has recently become available as a point of care test for Group A Streptococci (GAS) in individuals presenting with pharyngitis, enabling rapid and accurate diagnosis. However, swabbing the pharynx results in discomfort and is often dreaded by young children which may result in poor quality sampling.

Objective. In order to assess the viability of saliva as a sample specimen for GAS, this study compared saliva samples with pharynx swabs of children with sore throat, using swabs inoculated by children sucking on them as they would a lollipop in the context of newly available very sensitive techniques.

Methods. We enrolled children ages 5–15 years presenting with sore throat and known to have a positive rapid streptococcal antigen detection test (RADT) performed on a posterior pharyngeal swab, at the discretion of the primary care provider. The RADT used was the SureVue® (Fisher Scientific) system. A second swab was obtained by having the child suck on the swab in the anterior mouth for 30 seconds and a third swab was obtained from the posterior pharynx. PCR was performed on these two additional swabs using the cobas®/LIAT® (Roche) system according to the manufacturer’s instructions.

Results. Seventeen children were enrolled in the study between January and April 2019. The mean age of enrollment was 9.6 years (range 6–15). By design all children were known to have a positive RADT for GAS. The LIAT posterior pharynx swab was positive in all 17 subjects. In addition, the LIAT saliva swab was positive in all 17 subjects.

Conclusion. In this small pilot study, there was 100% concordance between the RADT for GAS and both the posterior pharyngeal and saliva swab using the
