Abstract

We obtain stability estimates and derive analytic expansions for local solutions of multi-dimensional quadratic BSDEs. We apply these results to a financial model where the prices of risky assets are quoted by a representative dealer in such a way that it is optimal to meet an exogenous demand. We show that the prices are stable under the demand process and derive their analytic expansions for small risk aversion coefficients of the dealer.

Keywords: multi-dimensional quadratic BSDEs, stability of quadratic BSDEs, asymptotic behavior of quadratic BSDEs, liquidity, price impact.

1 Introduction

One-dimensional Backward Stochastic Differential Equations (BSDEs) with quadratic growth are well-studied. Existence, uniqueness, and stability of their solutions for bounded terminal conditions have been established in the pioneering paper Kobylanski [10]. Generalizations to the unbounded case have been obtained in Briand and Hu [2, 3], and Briand and Elie [1] among others.

The situation with systems of quadratic BSDEs is more cumbersome. They may fail to have a solution even with bounded terminal conditions; see Frei and dos Reis [5]. On a positive side, existence and local uniqueness of solutions have been obtained for sufficiently small terminal conditions, first, in Tevzadze [12] for the $L_\infty$-norm and then in Frei [4] and Kramkov and Pulido [11] for the BMO-norm.

In this paper, we complement these results by establishing stability properties and deriving analytic expansions of such local solutions. Our main results are stated in Theorems 2.1 and 3.2. In Theorem 2.1, we get stability estimates with respect to the driver and the terminal condition. In Theorem 3.2 we obtain analytic expansions in BMO-spaces with respect to the terminal condition. The coefficients of these power series can be calculated recursively up to an arbitrary order.

This work is motivated by our study in [11] of a price impact model from the market microstructure theory; see also Grossman and Miller [8], Garleanu et al. [6], and German [7]. In this model, a representative dealer provides liquidity for risky stocks and quotes prices in such a way that it is optimal to meet an exogenous demand for stocks. It has been shown in [11] that the resulting stock prices can be characterized in terms of solutions to a system of quadratic BSDEs parametrized by the demand process.

If the demand is simple, then the stock prices exist and are unique. Moreover, they can be constructed explicitly by backward induction and martingale representation; see [7]. For general (non-simple) demands the situation is more involved. The existence and uniqueness of prices can be obtained only if the product of certain model parameters is sufficiently small; see [11] and condition (4.6) below. A natural question to ask is whether under such constraint the output stock prices are stable under demands and, in particular, whether they can be well approximated by the prices originated from simple demands. A positive answer is given in Theorem 4.3 and relies on the general stability estimates from Theorem 2.1.

As the dealer’s risk aversion coefficient $a$ approaches zero, the price impact effect vanishes and we arrive to a classical model of Mathematical
Finance. In Theorem 4.4 we derive an analytic expansion of prices for sufficiently small values of $a$, thus getting a natural scale of price impact corrections. The leading term of these corrections has been obtained in [7] for simple demands; see Remark 4.5.

**Notations**

For a matrix $A = (A^{ij})$ we denote its transpose by $A^*$ and define its norm as

$$|A| \triangleq \sqrt{\text{trace } AA^*} = \sqrt{\sum_{i,j} |A^{ij}|^2}.$$

We will work on a filtered probability space $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \in [0,T]}, \mathbb{P})$ satisfying the standard conditions of right-continuity and completeness; the initial $\sigma$-algebra $\mathcal{F}_0$ is trivial, $\mathcal{F}_T = \mathcal{F}_T$, and the maturity $T$ is finite. The expectation is denoted as $\mathbb{E}[-]$ and the conditional expectation with respect to $\mathcal{F}_t$ as $\mathbb{E}_t[-]$.

For an $n$-dimensional integrable random variable $\xi$ set

$$\|\xi\|_{\mathcal{L}^p} \triangleq (\mathbb{E}[|\xi|^p])^{1/p}, \quad p \geq 1,$$

$$\|\xi\|_{\mathcal{L}^\infty} \triangleq \inf \{c \geq 0 : |\xi(\omega)| \leq c, \mathbb{P}[d\omega] - a.s.\}.$$

We shall use the following spaces of stochastic processes:

$\text{BMO}(\mathbb{R}^n)$ is the Banach space of continuous $n$-dimensional martingales $M$ with $M_0 = 0$ and the norm

$$\|M\|_{\text{BMO}} \triangleq \sup \|\{\mathbb{E}_\tau[\langle M \rangle_T - \langle M \rangle_{\tau}]\}^{1/2}\|_{\mathcal{L}^\infty},$$

where the supremum is taken with respect to all stopping times $\tau$ and $\langle M \rangle$ is the quadratic variation of $M$.

$\mathcal{S}_{\text{BMO}}(\mathbb{R}^n)$ is the Banach space of continuous $n$-dimensional semimartingales $X = X_0 + M + A$, where $M$ is a continuous martingale and $A$ is a process of finite variation, with the norm

$$\|X\|_{\mathcal{S}_{\text{BMO}}} \triangleq |X_0| + \|M\|_{\text{BMO}} + \sup \|\mathbb{E}_\tau[\int_\tau^T |dA|]\|_{\mathcal{L}^\infty}.$$

Here the supremum is taken over all stopping times $\tau$ and $\int |dA|$ is the total variation of $A$. 

3
$\mathcal{S}_p(\mathbb{R}^n)$ for $p \geq 1$ is the Banach space of continuous $n$-dimensional semimartingales $X = X_0 + M + A$, where $M$ is a continuous martingale and $A$ is a process of finite variation, with the norm

$$\|X\|_{\mathcal{S}_p} \triangleq |X_0| + \|\langle M \rangle_T^{1/2}\|_{\mathcal{L}_p} + \int_0^T |dA|\|_{\mathcal{L}_p}.$$ 

$\mathcal{H}_0(\mathbb{R}^{n \times d})$ is the vector space of predictable processes $\zeta$ with values in $n \times d$-matrices such that $\int_0^T |\zeta_s|^2 \, ds < \infty$. This is precisely the space of $n \times d$-dimensional integrands $\zeta$ for a $d$-dimensional Brownian motion $B$. We shall identify $\alpha$ and $\beta$ in $\mathcal{H}_0(\mathbb{R}^{n \times d})$ if $\int_0^T |\alpha_s - \beta_s|^2 \, ds = 0$ or, equivalently, if the stochastic integrals $\alpha \cdot B$ and $\beta \cdot B$ coincide.

$\mathcal{H}_p(\mathbb{R}^{n \times d})$ for $p \geq 1$ consists of $\zeta \in \mathcal{H}_0(\mathbb{R}^{n \times d})$ such that $\zeta \cdot B \in \mathcal{S}_p(\mathbb{R}^n)$ for a $d$-dimensional Brownian motion $B$. It is a Banach space under the norm:

$$\|\zeta\|_{\mathcal{H}_p} \triangleq \|\zeta \cdot B\|_{\mathcal{S}_p} = \left\{ \mathbb{E} \left[ \left( \int_0^T |\zeta_s|^2 \, ds \right)^{p/2} \right] \right\}^{1/p}.$$

$\mathcal{H}_{\text{BMO}}(\mathbb{R}^{n \times d})$ consists of $\zeta \in \mathcal{H}_0(\mathbb{R}^{n \times d})$ such that $\zeta \cdot B \in \text{BMO}(\mathbb{R}^n)$ for a $d$-dimensional Brownian motion $B$. It is a Banach space under the norm:

$$\|\zeta\|_{\mathcal{H}_{\text{BMO}}} \triangleq \|\zeta \cdot B\|_{\text{BMO}} = \sup_{\tau} \left\{ \mathbb{E}_\tau \left[ \int_\tau^T |\zeta_s|^2 \, ds \right] \right\}^{1/2}.$$

$\mathcal{H}_\infty(\mathbb{R}^n)$ is the Banach space of bounded $n$-dimensional predictable processes $\gamma$ with the norm:

$$\|\gamma\|_{\mathcal{H}_\infty} \triangleq \inf \{ c \geq 0 : |\gamma_t(\omega)| \leq c, \ dt \times \mathbb{P}[d\omega] - \text{a.s.} \}.$$

For an $n$-dimensional integrable random variable $\xi$ with $\mathbb{E}[\xi] = 0$ set

$$\|\xi\|_{\mathcal{L}_{\text{BMO}}} \triangleq \| (\mathbb{E}[\xi]_t)_{t \in [0,T]} \|_{\text{BMO}}.$$

## 2 Stability estimates

Hereafter, we shall assume that
(A1) There exists a $d$-dimensional Brownian motion $B$ such that every local martingale $M$ is a stochastic integral with respect to $B$:

$$M = M_0 + \zeta \cdot B.$$ 

Of course, this assumption holds if the filtration is generated by $B$.

Consider the $n$-dimensional BSDE:

$$Y_t = \Xi + \int_t^T f(s, \zeta_s) \, ds - \int_t^T \zeta \, dB, \quad t \in [0, T].$$

Here $Y$ is an $n$-dimensional semimartingale, $\zeta$ is a predictable process with values in the space of $n \times d$ matrices, and the terminal condition $\Xi$ and the driver $f = f(t, z)$ satisfy the following assumptions:

(A2) $\Xi$ is an integrable random variable with values in $\mathbb{R}^n$ such that the martingale

$$L_t \triangleq \mathbb{E}_t[\Xi] - \mathbb{E}[\Xi], \quad t \in [0, T],$$

belongs to BMO.

(A3) $t \mapsto f(t, z)$ is a predictable process with values in $\mathbb{R}^n$,

$$f(t, 0) = 0,$$

and there is a constant $\Theta > 0$ such that

$$|f(t, u) - f(t, v)| \leq \Theta(|u - v|)(|u| + |v|),$$

for all $t \in [0, T]$ and $u, v \in \mathbb{R}^{n \times m}$.

Note that $f = f(t, z)$ has a quadratic growth in $z$.

Recall that there is a constant $\kappa = \kappa(n)$ such that, for every martingale $M \in \text{BMO}(\mathbb{R}^n)$,

$$\frac{1}{\kappa} \|M\|_{\text{BMO}} \leq \|M\|_{\text{BMO}} \triangleq \sup_{\tau} \mathbb{E}_\tau[|M_T - M_\tau|] \leq \|M\|_{\text{BMO}},$$

see [9], Corollary 2.1. Theorem A.1 in [11] shows that under (A1), (A2), and (A3), if

$$\|L\|_{\text{BMO}} < \frac{1}{8 \kappa \Theta},$$

then there exists a unique solution $(Y, \zeta)$ to (2.1) such that

$$\|\zeta\|_{\mathcal{X}_{\text{BMO}}} \leq \frac{1}{4 \kappa \Theta}.$$
The analogous local existence and uniqueness result was first shown in Proposition 1 in [12] for small bounded terminal conditions and then in Proposition 2.1 in [4] in the current BMO setting, but with different constants.

Theorem 2.1 below provides stability estimates for such local solution \((Y, \zeta)\) with respect to the terminal condition and the driver. Along with (2.1), we consider a similar \(n\)-dimensional BSDE
\[
Y'_t = \Xi' + \int_t^T f'(s, \zeta'_s) \, ds - \int_t^T \zeta' \, dB, \quad t \in [0, T],
\]
whose terminal condition \(\Xi'\) and the driver \(f' = f'(t, z)\) satisfy same conditions \((A2)\) and \((A3)\) as \(\Xi\) and \(f\). We denote
\[
L'_t \triangleq E_t[\Xi'] - E[\Xi'], \quad t \in [0, T],
\]
and assume that there exists a nonnegative process \(\delta = (\delta_t)\) such that
\[
|f(t, z) - f'(t, z)| \leq \delta_t |z|^2. \tag{2.4}
\]

**Theorem 2.1.** Assume that the BSDEs (2.1) and (2.3) satisfy \((A1), (A2), (A3),\) and (2.4) and let \((Y, \zeta)\) and \((Y', \zeta')\) be their respective solutions. For \(p > 1\) there are positive constants \(c = c(n, p)\) and \(C = C(n, p)\) (depending only on \(n\) and \(p\)) such that if
\[
\|\zeta\|_{\mathcal{H}^{BMO}} + \|\zeta'\|_{\mathcal{H}^{BMO}} \leq \frac{c}{3}, \tag{2.5}
\]
then
\[
\|\zeta' - \zeta\|_{\mathcal{F}_T} \leq C \left(\|L'_T - L_T\|_{\mathcal{F}_T} + \|\sqrt{\delta} \zeta\|_{\mathcal{F}^2_{2p}}\right), \tag{2.6}
\]
\[
\|Y' - Y\|_{\mathcal{F}_T} \leq C \left(\|\Xi' - \Xi\|_{\mathcal{F}_T} + \|\sqrt{\delta} \zeta\|_{\mathcal{F}^2_{2p}}\right). \tag{2.7}
\]

**Proof.** To shorten the notations set \(\Delta \zeta \triangleq \zeta' - \zeta\), etc. Define the martingale \(M\) and the process \(A\) of bounded variation as
\[
M \triangleq \Delta \zeta \cdot B,
\]
\[
A_t \triangleq \int_0^t (f'(s, \zeta'_s) - f(s, \zeta_s)) \, ds, \quad t \in [0, T].
\]

We deduce that
\[
M_T = \Delta L_T + A_T - E[A_T],
\]
and if
which readily implies that

\[ \|MT\|_{L^p} \leq \|\Delta L_T\|_{L^p} + 2\|AT\|_{L^p}. \]

From the Doob’s and Burkholder-Davis-Gundy’s (BDG) inequalities we deduce the existence of a constant \(C_1 = C_1(n, p)\) such that

\[ \|\Delta \zeta\|_{H^p} \leq C_1\|MT\|_{L^p}. \]

To estimate \(\|AT\|_{L^p}\) we use the potential \(Z\) associated with the variation of \(A:\)

\[
Z_t \triangleq \mathbb{E}_t \left[ \int_t^T |dA| + \int_t^T |f'(s, \zeta'_s) - f(s, \zeta_s)| \, ds \right] \leq \mathbb{E}_t \left[ \int_t^T |f'(s, \zeta'_s) - f'(s, \zeta_s)| \, ds \right] + \mathbb{E}_t \left[ \int_t^T |f'(s, \zeta_s) - f(s, \zeta_s)| \, ds \right].
\]

Denoting \(Z^* \triangleq \sup_{t \in [0,T]} |Z_t|\) we have, by the Garsia-Neveu inequality,

\[ \|AT\|_{L^p} \leq \|\int_0^T |dA|\|_{L^p} \leq P\|Z^*\|_{L^p}. \]

Take \(1 < p' < p\) and denote \(q' \triangleq \frac{p}{p'} - 1\). From (A3) and the Cauchy and Hölder inequalities we obtain

\[
U_t \triangleq \mathbb{E}_t \left[ \int_t^T |f'(s, \zeta'_s) - f'(s, \zeta_s)| \, ds \right] \leq \Theta \mathbb{E}_t \left[ \int_t^T (|\zeta_s| + |\zeta'_s|) |\Delta \zeta_s| \, ds \right] \\
\leq \Theta \mathbb{E}_t \left[ \left( \int_t^T (|\zeta_s| + |\zeta'_s|)^2 \, ds \right)^{1/2} \left( \int_t^T |\Delta \zeta_s|^2 \, ds \right)^{1/2} \right] \\
\leq \Theta \left( \mathbb{E}_t \left[ \left( \int_t^T (|\zeta_s| + |\zeta'_s|)^2 \, ds \right)^{q'/2} \right] \right)^{1/q'} \left( \mathbb{E}_t \left[ \left( \int_t^T |\Delta \zeta_s|^2 \, ds \right)^{p'/2} \right] \right)^{1/p'},
\]

From Doob’s inequality, the BDG inequalities, and the equivalence of BMO\(_p\)-norms, see [9], Corollary 2.1, p. 28, we deduce the existence of a constant \(C_2 = C_2(n, q')\) such that

\[
\left( \mathbb{E}_t \left[ \left( \int_t^T (|\zeta_s| + |\zeta'_s|)^2 \, ds \right)^{q'/2} \right] \right)^{1/q'} \leq C_2(||\zeta||_{\text{BMO}} + ||\zeta'||_{\text{BMO}}).
\]
Using the obvious estimate
\[ E_t \left[ \left( \int_t^T |\Delta \zeta_s|^2 \, ds \right)^{p'/2} \right] \leq E_t \left[ \left( \int_0^T |\Delta \zeta_s|^2 \, ds \right)^{p'/2} \right] \defeq N_t, \]
and denoting \( r \defeq p/p' > 1 \) we deduce from Doob’s inequality the existence of a constant \( C_3 = C_3(r) \) such that
\[ \|N^*\|_{\mathcal{L}} \leq C_3 \|N_T\|_{\mathcal{L}} = C_3 \|\Delta \zeta\|^p_{\mathcal{L}}, \]
Combining the above estimates we obtain
\[ \|U^*\|_{\mathcal{L}} \leq C_4 \Theta(\|\zeta\|_{\mathcal{BMO}} + \|\zeta'\|_{\mathcal{BMO}}) \|\Delta \zeta\|_{\mathcal{L}}, \]
where the constant \( C_4 = C_2 C_3^{1/p'} \) depends only on \( n \) and \( p \).
From (2.4) we deduce
\[ V_t \defeq E_t \left[ \int_t^T |f'(s, \zeta_s) - f(s, \zeta_s)| \, ds \right] \leq E_t \left[ \int_t^T \delta_s |\zeta_s|^2 \, ds \right] \]
\[ \leq E_t \left[ \int_0^T \delta_s |\zeta_s|^2 \, ds \right]. \]
Another application of Doob’s inequality yields a constant \( C_5 = C_5(p) \) such that
\[ \|V^*\|_{\mathcal{L}} \leq C_5 \int_0^T \delta_s |\zeta_s|^2 \, ds. \]
Defining the constants \( c = c(n, p) \) and \( C = C(n, p) \) as
\[ c = \frac{1}{4pC_1 C_4}, \]
\[ C = 2pC_1 \max(2C_5, 1), \]
and assuming (2.5) we obtain
\[ \|\Delta \zeta\|_{\mathcal{L}} \leq C_1 p(\|\Delta L_T\|_{\mathcal{L}} + 2\|Z^*\|_{\mathcal{L}}) \]
\[ \leq C_1 p(\|\Delta L_T\|_{\mathcal{L}} + 2\|U^*\|_{\mathcal{L}} + 2\|V^*\|_{\mathcal{L}}) \]
\[ \leq C_1 p \left( \|\Delta L_T\|_{\mathcal{L}} + 2C_4 \Theta(\|\zeta\|_{\mathcal{BMO}} + \|\zeta'\|_{\mathcal{BMO}}) \|\Delta \zeta\|_{\mathcal{L}} \right) \]
\[ + 2C_5 \int_0^T \delta_s |\zeta_s|^2 \, ds \]
\[ \leq \frac{1}{2} \|\Delta \zeta\|_{\mathcal{L}} + \frac{C}{2} \left( \|\Delta L_T\|_{\mathcal{L}} + \|\sqrt{\delta} \zeta\|^2_{\mathcal{L}} \right), \]
which implies \((2.6)\).

The estimate \((2.7)\) follows from \((2.6)\) and estimates above for \(\|f^T|dA|\|_{X_p}\) with appropriate \(C = C(n,p)\) as soon as we write
\[
\begin{align*}
\Delta Y_0 &= E[\Delta \Xi + A_T], \\
\Delta Y &= \Delta Y_0 + M - A,
\end{align*}
\]
with \(M\) and \(A\) defined at the beginning of the proof. 

\section{Analytic expansion for purely quadratic BSDE}

Consider an \(n\)-dimensional BSDE
\[
Y_t = a \Xi + \int_t^T f(s, \zeta_s) \, ds - \int_t^T \zeta \, dB, \quad t \in [0,T],
\]
where the terminal condition depends on a parameter \(a \in \mathbb{R}\). If \(\Xi\) and \(f\) satisfy \((A2)\) and \((A3)\) and \(|a| < \rho\), where
\[
\rho \triangleq \frac{1}{8K\Theta\|L\|_{BMO}},
\]
then, by Theorem A.1 in [11], there is only one solution \((Y(a), \zeta(a))\) such that
\[
\|\zeta(a)\|_{\mathcal{H}\mathcal{BMO}} \leq \frac{1}{4K\Theta},
\]
and for this solution we have an estimate:
\[
\|\zeta(a)\|_{\mathcal{H}\mathcal{BMO}} \leq 2|a|\|L\|_{\mathcal{BMO}}.
\]
In particular, \(\zeta(a)\) converges to 0 in \(\mathcal{H}\mathcal{BMO}\) as \(a\) approaches 0.

In Theorem 3.2 below we obtain an analytic expansion for \(\zeta(a)\) in the neighborhood of \(a = 0\) under the additional assumption that the driver \(f = f(t, z)\) is purely quadratic in \(z\):
\[
\begin{align*}
(A4) \quad f(t, z) &= \tilde{f}(t, z, z), \text{ where for all } u, v \in \mathbb{R}^{n \times d} \text{ the map } t \mapsto \tilde{f}(t, u, v) \\
\text{is a } \mathbb{R}^n\text{-valued predictable process and for every } t \in [0, T] \text{ the map } \\
(u, v) \mapsto \tilde{f}(t, u, v) \text{ is a bilinear form on } \mathbb{R}^{n \times d} \times \mathbb{R}^{n \times d} \text{ bounded by a constant } \Theta > 0. \text{ In other words,}
\end{align*}
\]
\[
\begin{align*}
\tilde{f}(t, \lambda u, v + w) &= \tilde{f}(t, \lambda(v + w), u) = \lambda(\tilde{f}(t, u, v) + \tilde{f}(t, u, w)), \\
\left| \tilde{f}(t, u, v) \right| &\leq \Theta |u| |v|,
\end{align*}
\]
for all \(t \in [0, T], \lambda \in \mathbb{R}, \) and \(u, v, w \in \mathbb{R}^{n \times d}\).
Notice that (A4) implies (A3):
\[
|f(t, u) - f(t, v)| = |\tilde{f}(t, u, u) - \tilde{f}(t, v, v)| = \Theta(|u - v|) \leq \Theta(|u| + |v|).
\]

To state Theorem 3.2 we need the following technical result.

**Lemma 3.1.** Assume (A1) and (A4). For \(\mu, \nu \in \mathcal{H}_{\text{BMO}}\) there is a unique \(\zeta \in \mathcal{H}_{\text{BMO}}\) such that
\[
(3.4) \quad (\zeta \cdot B) = \mathbb{E}_t \left[ \int_0^T \tilde{f}(t, \mu_t, \nu_t) \, dt \right] - \mathbb{E}_t \left[ \int_0^T \tilde{f}(t, \mu_t, \nu_t) \, dt \right].
\]
Moreover,
\[
\|\zeta\|_{\mathcal{H}_{\text{BMO}}} \leq 2\kappa\Theta \|\mu\|_{\mathcal{H}_{\text{BMO}}} \|\nu\|_{\mathcal{H}_{\text{BMO}}},
\]
where the positive constants \(\kappa\) and \(\Theta\) are defined in (2.2) and (A4).

**Proof.** Define the martingale
\[
M_t = \mathbb{E}_t \left[ \int_0^T \tilde{f}(t, \mu_t, \nu_t) \, dt \right] - \mathbb{E}_t \left[ \int_0^T \tilde{f}(t, \mu_t, \nu_t) \, dt \right].
\]
For a stopping time \(\tau\) we deduce from (A4) and the Cauchy’s inequality that
\[
\mathbb{E}_\tau[|M_T - M_\tau|] = \mathbb{E}_\tau \left[ \left| \int_0^T \tilde{f}(s, \mu_s, \nu_s) \, ds - \mathbb{E}_\tau \left[ \int_0^T \tilde{f}(s, \mu_s, \nu_s) \, ds \right] \right| \right]
\leq 2\mathbb{E}_\tau \left[ \int_0^T |\tilde{f}(s, \mu_s, \nu_s)| \, ds \right] \leq 2\Theta\mathbb{E}_\tau \left[ \left| \int_0^T \mu_s \, ds \right| \right] \leq 2\Theta \left( \mathbb{E}_\tau \left[ \int_0^T |\mu_s|^2 \, ds \right] \right) \left( \mathbb{E}_\tau \left[ \int_0^T |\nu_s|^2 \, ds \right] \right)^{1/2}.
\]
Hence,
\[
\|M\|_{\text{BMO}} \leq \kappa \sup_\tau \mathbb{E}_\tau[|M_T - M_\tau|] \leq 2\kappa\Theta \|\mu\|_{\mathcal{H}_{\text{BMO}}} \|\nu\|_{\mathcal{H}_{\text{BMO}}},
\]
and the result follows because, in view of (A1), \(M\) admits an integral representation \(\zeta \cdot B\) for some unique \(\zeta \in \mathcal{H}_{\text{BMO}}\).

Lemma 3.1 allows us to define the map
\[
\bar{F} : \mathcal{H}_{\text{BMO}} \times \mathcal{H}_{\text{BMO}} \rightarrow \mathcal{H}_{\text{BMO}}
\]
such that \(\zeta = \bar{F}(\mu, \nu)\) is given by (3.4). This map is bilinear (since \(\tilde{f}(t, \cdot, \cdot)\) is bilinear) and is bounded by \(2\kappa\Theta\).

Recall the constant \(\rho\) from (3.2) and the BMO martingale \(L\) from (A2).
Theorem 3.2. Assume \((A1), (A2),\) and \((A4)\). Then for \(|a| < \rho\) there is only one solution \((Y(a), \zeta(a))\) to (3.1) satisfying (3.3). It is given by the power series

\[
Y(a) = \sum_{k=1}^{\infty} Y^{(k)} a^k \quad \text{and} \quad \zeta(a) = \sum_{k=1}^{\infty} \zeta^{(k)} a^k
\]

convergent for \(|a| < \rho\) in \(\mathcal{F}_{\text{BMO}}\) and \(\mathcal{H}_{\text{BMO}}\) respectively with the coefficients

\[
(3.5) \quad Y_t^{(1)} = \mathbb{E}_t[\Xi], \quad t \in [0, T],
\]

\[
(3.6) \quad \zeta^{(1)} \cdot B = L,
\]

and, for \(k \geq 2\),

\[
(3.7) \quad \zeta^{(k)} = \sum_{l+m=k} \tilde{F}(\zeta^{(l)}, \zeta^{(m)}),
\]

\[
(3.8) \quad Y_t^{(k)} = \sum_{l+m=k} \mathbb{E}_t[\int_t^T \tilde{f}(s, \zeta_s^{(l)}, \zeta_s^{(m)}) ds], \quad t \in [0, T],
\]

where we sum with respect to all pairs of positive integers \((l, m)\) which add to \(k\).

The proof relies on some lemmas.

Lemma 3.3. Assume \((A1), (A2),\) and \((A4)\). Let \((\zeta^{(k)})_{k \geq 1}\) be given by (3.6)-(3.7). Then \((\zeta^{(k)})_{k \geq 1} \subset \mathcal{H}_{\text{BMO}}\) and

\[
(3.9) \quad \sum_{k=1}^{\infty} \|\zeta^{(k)}\|_{\mathcal{H}_{\text{BMO}}} \rho^k \leq \frac{1}{4 \kappa \Theta}.
\]

Proof. The claim that each \(\zeta^{(k)}\) belongs to \(\mathcal{H}_{\text{BMO}}\) follows from its construction and Lemma 3.1. For \(n \geq 1\) define the partial sums

\[
s_n \triangleq \sum_{k=1}^{n} \|\zeta^{(k)}\|_{\mathcal{H}_{\text{BMO}}} \rho^k.
\]
Using the boundedness of the bilinear form $\tilde{F}$ by $2\kappa \Theta$ we obtain

\[ s_n - s_1 = \sum_{k=2}^{n} \| \zeta^{(k)} \|_{\mathcal{H}_{BMO}} \rho^k \leq \sum_{k=2}^{n} \left( \sum_{l+m=k} \| \tilde{F}(\zeta^{(l)}, \zeta^{(m)}) \|_{\mathcal{H}_{BMO}} \right) \rho^k \]

\[ \leq 2\kappa \Theta \sum_{k=2}^{n} \sum_{l+m=k} (\| \zeta^{(l)} \|_{\mathcal{H}_{BMO}} \rho^l) (\| \zeta^{(m)} \|_{\mathcal{H}_{BMO}} \rho^m) \]

\[ \leq 2\kappa \Theta \sum_{l,m=1}^{n-1} (\| \zeta^{(l)} \|_{\mathcal{H}_{BMO}} \rho^l) (\| \zeta^{(m)} \|_{\mathcal{H}_{BMO}} \rho^m) \]

\[ = 2\kappa \Theta \left( \sum_{k=1}^{n-1} \| \zeta^{(k)} \|_{\mathcal{H}_{BMO}} \rho^k \right)^2 = 2\kappa \Theta (s_{n-1})^2. \]

To verify (3.9) we use an induction argument. For $n = 1$ we have

\[ s_1 = \| \zeta^{(1)} \|_{\mathcal{H}_{BMO}} \rho = \rho \| L \|_{BMO} = \frac{1}{8\kappa \Theta}. \]

If now $s_{n-1} \leq 1/(4\kappa \Theta)$, then

\[ s_n \leq s_1 + 2\kappa \Theta (s_{n-1})^2 \leq \frac{1}{8\kappa \Theta} + 2\kappa \Theta \left( \frac{1}{4\kappa \Theta} \right)^2 = \frac{1}{4\kappa \Theta} \]

and (3.9) follows. \qed

**Lemma 3.4.** Assume (A1) and (A4). For $\mu, \nu \in \mathcal{H}_{BMO}$ the process

\[ X_t \triangleq \mathbb{E}_t \left[ \int_t^T \tilde{f}(s, \mu_s, \nu_s) \, ds \right], \quad t \in [0, T], \]

belongs to $\mathcal{H}_{BMO}$ and

\[ \| X \|_{\mathcal{H}_{BMO}} \leq 2(1 + \kappa) \Theta \| \mu \|_{\mathcal{H}_{BMO}} \| \nu \|_{\mathcal{H}_{BMO}}. \]

**Proof.** The canonical decomposition of the semimartingale $X$ has the form

\[ X = X_0 + M - A, \]

where

\[ A_t = \int_0^t \tilde{f}(s, \mu_s, \nu_s) \, ds, \]

\[ X_0 = \mathbb{E}[A_T], \]

\[ M_t = \mathbb{E}_t[A_T] - \mathbb{E}[A_T]. \]

12
By Lemma 3.1 we have
\[ \|M\|_{\text{BMO}} \leq 2\kappa \Theta \|\mu\|_{\mathcal{H}_{\text{BMO}}} \|\nu\|_{\mathcal{H}_{\text{BMO}}}. \]

As in the proof of Lemma 3.1 we deduce that for any stopping time \( \tau \)
\[ \mathbb{E}_\tau \left[ \int_\tau^T |dA| \right] = \mathbb{E}_\tau \left[ \int_\tau^T \left| \tilde{f}(s, \mu_s, \nu_s) \right| ds \right] \leq \Theta \|\mu\|_{\mathcal{H}_{\text{BMO}}} \|\nu\|_{\mathcal{H}_{\text{BMO}}} \]
and the result readily follows. \( \square \)

**Proof of Theorem 3.2.** Take \( a \in \mathbb{R} \) such that \( |a| < \rho \). Recall that (A4) implies (A3). Theorem A.1 in [11] then implies the existence and uniqueness of the solution \( \zeta(a) \) satisfying (3.3). To show that

\[ (3.10) \quad \zeta(a) = \beta \triangleq \sum_{k=1}^\infty \zeta^{(k)} a^k, \]

we need to verify that \( \beta \) is a fixed point of the map \( F : \mathcal{H}_{\text{BMO}} \to \mathcal{H}_{\text{BMO}} \) given by
\[ F(\zeta) \triangleq a \zeta^{(1)} + \tilde{F}(\zeta, \zeta). \]

For \( n \geq 1 \) define the partial sums:
\[ \beta_n \triangleq \sum_{k=1}^n \zeta^{(k)} a^k. \]

In view of Lemma 3.3, the processes \( \beta \) and \( \beta_n \) belong to \( \mathcal{H}_{\text{BMO}} \) and
\[ \|\beta - \beta_n\|_{\mathcal{H}_{\text{BMO}}} \leq \sum_{k=n+1}^\infty \|\zeta^{(k)}\|_{\mathcal{H}_{\text{BMO}}} \rho^k \rightarrow 0, \quad n \rightarrow \infty. \]

The bilinearity of \( \tilde{F} \) and Lemma 3.1 then yield
\[ \|F(\beta) - F(\beta_n)\|_{\mathcal{H}_{\text{BMO}}} \leq \|\tilde{F}(\beta, \beta) - \tilde{F}(\beta_n, \beta_n)\|_{\mathcal{H}_{\text{BMO}}} \]
\[ = \|\tilde{F}(\beta - \beta_n, \beta + \beta_n)\|_{\mathcal{H}_{\text{BMO}}} \]
\[ \leq 2\kappa \Theta \|\beta - \beta_n\|_{\mathcal{H}_{\text{BMO}}} (\|\beta\|_{\mathcal{H}_{\text{BMO}}} + \|\beta_n\|_{\mathcal{H}_{\text{BMO}}}) \rightarrow 0, \quad n \rightarrow \infty, \]

and to conclude the proof of (3.10) we only have to show that

\[ (3.11) \quad \|F(\beta_n) - \beta_n\|_{\mathcal{H}_{\text{BMO}}} \rightarrow 0, \quad n \rightarrow \infty. \]

13
From the bilinearity of $\tilde{F}$ and the construction of $(\zeta^{(k)})$ we deduce that

$$F(\beta_n) - \beta_n = \tilde{F}(\sum_{k=1}^{n} \zeta^{(k)}a^k, \sum_{k=1}^{n} \zeta^{(k)}a^k) - \sum_{k=2}^{n} \zeta^{(k)}a^k$$

$$= \sum_{l,m=1}^{n} \tilde{F}(\zeta^{(l)}, \zeta^{(m)})a^{l+m} - \sum_{k=2}^{n} \left( \sum_{l+m=k}^{n} \tilde{F}(\zeta^{(l)}, \zeta^{(m)}) \right) a^k$$

$$= \sum_{1 \leq l,m \leq n, l+m>n} \tilde{F}(\zeta^{(l)}, \zeta^{(m)})a^{l+m}.$$  

Using the boundedness of the bilinear form $\tilde{F}$ by $2\kappa\Theta$ we obtain

$$\|F(\beta_n) - \beta_n\|_{\mathcal{H}_{BMO}} \leq 2\kappa\Theta \sum_{l+m>n} \|\zeta^{(l)}\|_{\mathcal{H}_{BMO}} \|\zeta^{(m)}\|_{\mathcal{H}_{BMO}} \rho^{l+m}$$

$$\leq 2\kappa\Theta \left( \left( \sum_{k=1}^{\infty} \|\zeta^{(k)}\|_{\mathcal{H}_{BMO}} \rho^{k} \right)^2 - \left( \sum_{k=1}^{[n/2]} \|\zeta^{(k)}\|_{\mathcal{H}_{BMO}} \rho^{k} \right)^2 \right)$$

and (3.11) follows from Lemma 3.3.

The power series representation for $Y(a)$ and formulas (3.5) and (3.8) for its coefficients readily follow from the expansion for $\zeta(a)$ as soon as we write $Y(a)$ as

$$Y_t(a) = a\mathbb{E}_t[\Xi] + \mathbb{E}_t[\int_t^T \tilde{f}(s, \xi_s(a), \zeta_s(a))ds], \quad t \in [0, T],$$

and use the bilinearity of $\tilde{f}$ and Lemma 3.4.

## 4 Applications to a price impact model

We consider a financial model of price impact studied in Garleanu et al. [6], German [7], and Kramkov and Pulido [11]. There is a representative dealer whose preferences regarding terminal wealth are modeled by the exponential utility

$$U(x) = -\frac{1}{a}e^{-ax}, \quad x \in \mathbb{R}.$$ 

The risk aversion coefficient $a > 0$ defines the strength of the price impact effect. In particular, as $a \downarrow 0$ we are getting the classical impact-free model of Mathematical Finance; see Section 4.2.
The financial market consists of a bank account and \( n \) stocks. The bank account pays zero interest rate. The stocks pay dividends \( \Psi = (\Psi^i)_{i=1,\ldots,n} \) at maturity \( T \); each \( \Psi^i \) is a random variable. While the terminal stocks’ prices \( S_T \) are always given by \( \Psi \), their intermediate values \( S_t \) on \([0, T]\) are affected by an exogenous demand process \( \gamma \) through the following equilibrium mechanism.

**Definition 4.1.** A predictable process \( \gamma \) with values in \( \mathbb{R}^n \) is called a demand. The demand \( \gamma \) is viable if there is an \( n \)-dimensional semimartingale of stock prices \( S \) with terminal value \( S_T = \Psi \) such that the pricing probability measure \( Q \) is well-defined by

\[
\frac{dQ}{dP} \triangleq e^{-a \int_0^T \gamma dB} = \frac{e^{-a \int_0^T \gamma_0^T \gamma dS}}{e^{-a \int_0^T \gamma dS}}
\]

and \( S \) and the stochastic integral \( \gamma \cdot S \) are uniformly integrable martingales under \( Q \).

Lemma 2.2 in [11] clarifies the economic meaning of Definition 4.1. It shows that a demand \( \gamma \) is viable if and only if it defines the optimal number of stocks for the dealer trading at stock prices \( S = S(\gamma) \).

Under (A1), for a viable demand \( \gamma \) accompanied by stocks’ prices \( S \) and the pricing measure \( Q \) there are unique processes \( \alpha \in \mathcal{H}_0(\mathbb{R}^d) \) and \( \sigma \in \mathcal{H}_0(\mathbb{R}^{n \times d}) \), called, respectively, the market price of risk and the volatility, such that

\[
\frac{dQ}{dP} = e^{-a \int_0^T \alpha dB - \frac{1}{2} \int_0^T |\alpha|^2 dt},
\]

\[
S = S_0 + \int \sigma \alpha dt + \sigma \cdot B.
\]

Theorem 3.1 in [11] characterizes \( S, \alpha, \) and \( \sigma \) in terms of solutions to a system of quadratic BSDEs. More precisely, it states that a demand \( \gamma \) is viable and is accompanied by the stock prices \( S \) if and only if there are a one-dimensional semimartingale \( R \) and predictable processes \( \eta \in \mathcal{H}_0(\mathbb{R}^d) \), and \( \theta \in \mathcal{H}_0(\mathbb{R}^{n \times d}) \), such that, for every \( t \in [0, T] \),

\[
(4.1) \quad aR_t = \frac{1}{2} \int_t^T (|\theta_s^\gamma|_s^2 - |\eta_s|^2) ds - \int_t^T \eta dB,
\]

\[
(4.2) \quad aS_t = a\Psi - \int_t^T \theta_s (\eta_s + \theta_s^\gamma_s) ds - \int_t^T \theta dB,
\]
and such that the stochastic exponential \( Z \triangleq \mathcal{E}((\eta + \theta^* \gamma) \cdot B) \) and the processes \( ZS \) and \( Z(\gamma \cdot S) \) are (uniformly integrable) martingales.

In this case, \( Z \) is the density process of the pricing measure \( \mathbb{Q} \), and the market price of risk \( \alpha \) and the volatility \( \sigma \) are given by

\[
\alpha = \eta + \theta^* \gamma, \\
\sigma = \theta/a. 
\] (4.3) (4.4)

The value of the auxiliary process \( R \) at time \( t \) can be written as

\[
R_t \triangleq U^{-1} \left( \mathbb{E}_t \left[ U \left( \int_t^T \gamma dS \right) \right] \right) = \frac{1}{a} \log \left( \mathbb{E}_t \left[ e^{-a \int_t^T \gamma dS} \right] \right),
\]

and thus represents the dealer’s certainty equivalent value of the remaining gain \( \int_t^T \gamma dS \).

**Remark 4.2.** From Definition 4.1 we deduce that the dependence of stocks’ prices \( S = S(\gamma, a, \Psi) \) on the viable demand \( \gamma \), on the risk-aversion coefficient \( a \), and on the dividend \( \Psi \) has the following homogeneity properties: for \( b > 0 \),

\[
S(b\gamma, a, \Psi) = S(\gamma, ba, \Psi) = \frac{1}{b} S(\gamma, a, b\Psi).
\]

This yields similar properties of the market prices of risk \( \alpha = \alpha(\gamma, a, \Psi) \) and of the volatilities \( \sigma = \sigma(\gamma, a, \Psi) \):

\[
\alpha(b\gamma, a, \Psi) = \alpha(\gamma, ba, \Psi) = \alpha(\gamma, a, b\Psi), \\
\sigma(b\gamma, a, \Psi) = \sigma(\gamma, ba, \Psi) = \frac{1}{b} \sigma(\gamma, a, b\Psi). 
\] (4.5)

### 4.1 Stability with respect to demand

A demand \( \gamma \) is called *simple* if it has the form:

\[
\gamma = \sum_{i=0}^{m-1} \theta_i 1_{(\tau_i, \tau_{i+1}]},
\]

where \( 0 = \tau_0 < \tau_1 < \cdots < \tau_m = T \) are stopping times and \( \theta_i \) is a \( \mathcal{F}_{\tau_i} \)-measurable random variable with values in \( \mathbb{R}^n \), \( i = 0, \ldots, m-1 \). Theorem 1 in [7] shows that every bounded simple demand \( \gamma \) is viable provided that the dividends \( \Psi = (\Psi^i) \) have all exponential moments. Moreover, in this case, the price process \( S = S(\gamma) \) is unique and is constructed explicitly, by backward induction.
For general (non-simple) demands the situation is more involved. As Proposition 4.3 in [11] shows, even for bounded dividends \( \Psi \) and demands \( \gamma \), either existence or uniqueness of prices \( S = S(\gamma) \) may fail. On a positive side, by Theorem 4.1 in [11], there is a constant \( c = c(n) > 0 \) (dependent only on the number of stocks \( n \)) such that if

\[
(4.6) \quad a \| \gamma \|_{L^\infty} \| \Psi - \mathbb{E}[\Psi] \|_{L^BMO} \leq c,
\]

then the prices \( S = S(\gamma) \) exist and are unique.

The following theorem shows that under (4.6) the prices \( S = S(\gamma) \) are stable under small changes in the demand \( \gamma \). In particular, they can be well approximated by the prices originated from simple demands.

**Theorem 4.3.** Assume \((A1)\) and let \( p > 1 \). There is a constant \( c = c(n, p) > 0 \) such that if \((\gamma^m)_{m \geq 1}\) and \( \gamma \) are elements of \( H^\infty(\mathbb{R}^n) \) such that

\[
(4.7) \quad a \| \gamma^m \|_{L^\infty} \| \Psi - \mathbb{E}[\Psi] \|_{L^BMO} \leq c, \quad m \geq 1,
\]

and

\[
\mathbb{E} \left[ \int_0^T |\gamma^m_t - \gamma_t| \, dt \right] \to 0, \quad n \to \infty,
\]

then \((\gamma^m)_{m \geq 1}\) and \( \gamma \) are viable demands and the corresponding stock prices \((S^m)_{m \geq 1}\) and \( S \), volatilities \((\sigma^m)_{m \geq 1}\) and \( \sigma \), and the market prices of risk \((\alpha^m)_{m \geq 1}\) and \( \alpha \) converge as

\[
(4.8) \quad \| S^m - S \|_{\mathcal{L}^p} + \| \sigma^m - \sigma \|_{\mathcal{H}^p} + \| \alpha^m - \alpha \|_{\mathcal{H}^p} \to 0, \quad m \to \infty.
\]

**Proof.** Observe that the self-similarity relations (4.5) for the market prices of risk and volatilities allow us to assume that

\[
a = 1 \geq \| \gamma^m \|_{L^\infty}, \quad m \geq 1.
\]

Clearly, \( \gamma \) satisfies (4.6) with same constant \( c \) as in (4.7). By Theorem 4.1 in [11], we can choose \( c = c(n) \) so that the demands \((\gamma^m)\) and \( \gamma \) are viable and are accompanied by unique stock prices. Using Theorem 2.1 and the BSDE characterizations (4.1)–(4.4) we can also choose \( c = c(n, p) \) so that

\[
\| S^m - S \|_{\mathcal{L}^p} + \| \sigma^m - \sigma \|_{\mathcal{H}^p} + \| \alpha^m - \alpha \|_{\mathcal{H}^p} \leq C \left( \int_0^T |\gamma^m_t - \gamma_t| \left( |\alpha_t|^2 + |\sigma_t|^2 \right) dt \right)_{\mathcal{L}^p},
\]

for some \( C = C(n, p) \). This yields (4.8) by the dominated convergence theorem. \( \square \)
4.2 Asymptotic expansion for small risk-aversion

As the risk aversion coefficient $a$ approaches zero, the price impact effect vanishes and we obtain classical model of Mathematical Finance. Theorem 4.4 below provides analytic expansions of volatilities and market prices of risk in the neighborhood of $a = 0$. The terms in these expansions are computed recursively, by martingale representation and, thus, are quite explicit.

We write $z \in \mathbb{R}^{(n+1) \times m}$ as $z = (z_1, z_2)$ with $z_1 \in \mathbb{R}^m$ and $z_2 \in \mathbb{R}^{n \times m}$, the decomposition of $(n+1) \times m$-dimensional matrix on its first and subsequent rows; hereafter $m = 1$ or $d$, the dimension of underlying Brownian motion from (A1).

For a vector $w \in \mathbb{R}^n$ consider the bilinear form:

\[
g(\cdot; w) = (g_1, g_2)(\cdot; w) : \mathbb{R}^{(n+1) \times d} \times \mathbb{R}^{(n+1) \times d} \to \mathbb{R}^{n+1}
\]

defined for $u = (u_1, u_2)$ and $v = (v_1, v_2)$ from $\mathbb{R}^{(n+1) \times d}$ as

\[
g_1(u, v; w) \triangleq \frac{1}{2}((u_2^* w, v_2^* w) - (u_1, v_1))
\]

\[
g_2(u, v; w) \triangleq -\frac{1}{2}(u_2 v_1 + v_2 u_1 + (u_2 v_2 + v_2 u_2) w),
\]

where $\langle x, y \rangle$ denotes the scalar product of $x, y \in \mathbb{R}^m$.

Take $\gamma \in \mathbb{H}_\infty(\mathbb{R}^n)$. Lemma 3.1 shows that for $\mu$ and $\nu$ in $\mathbb{H}_{\text{BMO}}(\mathbb{R}^{(n+1) \times d})$ there is a unique $\zeta \in \mathbb{H}_{\text{BMO}}(\mathbb{R}^{(n+1) \times d})$ such that

\[
(4.9) \quad \int_0^t \zeta dB = \mathbb{E}_t[\int_0^T g(\mu_s, \nu_s; \gamma_s) ds] - \mathbb{E}[\int_0^T g(\mu_s, \nu_s; \gamma_s) ds].
\]

Hence, we can define a bilinear form

\[
G(\cdot; \cdot; \gamma) : \mathbb{H}_{\text{BMO}}(\mathbb{R}^{(n+1) \times d}) \times \mathbb{H}_{\text{BMO}}(\mathbb{R}^{(n+1) \times d}) \to \mathbb{H}_{\text{BMO}}(\mathbb{R}^{(n+1) \times d})
\]

with $\zeta = G(\mu, \nu; \gamma)$ given by (4.9).

Denote also by $S(0)$ and $\sigma(0)$ the unperturbed stocks’ prices and volatilities corresponding to the case $\gamma = 0$:

\[
S_t(0) = \mathbb{E}_t[\Psi] = S_0(0) + \int_0^t \sigma(0) dB, \quad t \in [0, T].
\]

**Theorem 4.4.** Assume (A1) and that

\[
0 < \|\Psi - \mathbb{E}[\Psi]\|_{\mathbb{H}_{\text{BMO}}} < \infty.
\]
There is a constant $c = c(n) > 0$ such that if $\gamma \in \mathcal{H}_\infty(\mathbb{R}^n)$, $\gamma \neq 0$, and the risk-aversion satisfies

\[(4.10)\quad 0 < a < \rho \triangleq \frac{c}{\|\gamma\|_{\mathcal{H}_\infty} \|\Psi - \mathbb{E}[\Psi]\|_{\mathcal{L}_{\text{BMO}}}},\]

then $\gamma$ is a viable demand. The price $S(\gamma; a)$ is unique and admits the power series expansion in $\mathcal{H}_{\text{BMO}}$: \[
S(\gamma; a) = S(0) + \sum_{k=1}^{\infty} S^{(k)} a^k, \quad a < \rho.
\]

The market price of risk $\alpha(\gamma; a)$ and the volatility $\sigma(\gamma; a)$ have the power series expansions in $\mathcal{H}_\infty$: \[
\alpha(\gamma; a) = \sum_{k=1}^{\infty} (\zeta_1^{(k)} + (\zeta_2^{(k)})^* \gamma) a^k, \quad a < \rho,
\]
\[
\sigma(\gamma; a) = \sum_{k=0}^{\infty} \zeta_2^{(k+1)} a^k, \quad a < \rho.
\]

Here the coefficients $\zeta^{(k)} = (\zeta_1^{(k)} \zeta_2^{(k)}), k \geq 1$, in $\mathcal{H}_{\text{BMO}}(\mathbb{R}^{(n+1) \times d})$ are given recursively as \[
(4.11) \quad \zeta^{(1)} = (\zeta_1^{(1)} \zeta_2^{(1)}) = (0, \sigma(0)),
\]
\[
(4.12) \quad \zeta^{(k)} = \sum_{l+m=k} G(\zeta^{(l)} \zeta^{(m)}; \gamma), \quad k \geq 2,
\]

and the coefficients $(S^{(k)})_{k \geq 1} \subset \mathcal{H}_{\text{BMO}}(\mathbb{R}^n)$ are given by \[
S^{(k)}_t = - \sum_{l+m=k+1} \mathbb{E}_t \left[ \int_t^T \zeta^{(l)}_{2,s}(\zeta_1^{(m)} + (\zeta_2^{(m)})^* \gamma_s) ds \right], \quad t \in [0, T].
\]

**Remark 4.5.** The leading price impact coefficient in the expansion for stock prices is given by \[
S^{(1)}_t = - \mathbb{E}_t \left[ \int_t^T \sigma_s(0) \sigma_s(0)^* \gamma_s ds \right], \quad t \in [0, T].
\]

This result had been obtained earlier in Theorem 2 of [7] for a simple demand.
Proof of Theorem 4.4. Theorem 4.1 in [11] yields the existence of a constant $c = c(n)$ such that, under (4.10), $\gamma$ is a viable demand accompanied by the unique price process $S = S(\gamma, a)$. Observe that the dependence of the coefficients $\zeta^{(k)}$ on $\gamma$ and $\sigma(0)$ has the homogeneity properties:

$$
\zeta^{(k)}_1(b\gamma, \sigma(0)) = b^k \zeta^{(k)}_1(\gamma, \sigma(0)),
$$

$$
\zeta^{(k)}_2(b\gamma, \sigma(0)) = b^k \zeta^{(k)}_2(\gamma, \sigma(0)), \quad b > 0,
$$

which can be verified by induction. In view of these properties and the self-similarity relations (4.5) for the market prices of risk and volatilities, we can assume, without a loss in generality, that

$$
\|\gamma\|_{H^\infty} = \|\sigma(0)\|_{\mathcal{BMO}} = 1.
$$

In this case, the stochastic bilinear form $g(\cdot, \cdot; \gamma)$ is bounded by a constant $\Theta = \Theta(n)$ such that

$$
|g(u, v; w)| \leq \Theta |u| |v| \text{ for every } w \in \mathbb{R}^n \text{ with } |w| \leq 1.
$$

Taking now the constant $c$ also smaller than $1/(4\Theta \kappa)$, where $\kappa = \kappa(n)$ is defined in (2.2) below, we deduce from Theorem 3.2 the existence and uniqueness of $\eta = \eta(a) \in \mathcal{H}_{\mathbb{BMO}}(\mathbb{R}^d)$ and $\theta = \theta(a) \in \mathcal{H}_{\mathbb{BMO}}(\mathbb{R}^{n \times d})$ solving (4.1)–(4.2) and such that

$$
\sqrt{\|\eta\|^2_{\mathcal{H}_{\mathbb{BMO}}} + \|\theta\|^2_{\mathcal{H}_{\mathbb{BMO}}}} \leq \frac{1}{4\kappa \Theta}.
$$

Moreover, the maps $a \mapsto \eta(a)$ and $a \mapsto \theta(a)$ of $(-\rho, \rho)$ to $\mathcal{H}_{\mathbb{BMO}}$ are analytic, and their power series are given by

$$
\eta(a) = \sum_{k=1}^{\infty} \zeta^{(k)}_1 a^k,
$$

$$
\theta(a) = \sum_{k=1}^{\infty} \zeta^{(k)}_2 a^k,
$$

with the coefficients $\zeta^{(k)} = (\zeta^{(k)}_1, \zeta^{(k)}_2)$, $k \geq 1$, in $\mathcal{H}_{\mathbb{BMO}}(\mathbb{R}^{(n+1) \times d})$ determined by (4.11)–(4.12). The power series expansions for $S$ follow from Theorem 3.2, while the expansions for $\alpha$ and $\sigma$ follow from the linear invertibility relations (4.3)–(4.4) between $(\alpha, \sigma)$ and $(\eta, \theta)$.
