ABSTRACT

A total no of 119 cases of thyroid lesions were subjected to FNAC and were analyzed. Most of the cases occurred in females 113 (94.96%) and 6 cases were noticed in males (5.04%). Maximum number of lesions was seen in age group 21 to 30 years (39 cases). Cytological diagnosis was given in 119 cases. Benign lesions constituted 108 cases whereas malignant lesions were 11. Nodular goiter was the commonest benign lesion and papillary carcinoma of thyroid was commonest malignant lesion. AgNOR scoring was given in 100 cases and in 19 cases AgNOR scoring was not given due to poor cellularity of smears. The number of benign lesions was 90 and malignant lesions were 10. In the present study malignant thyroid lesions (papillary carcinoma) showed AgNOR scoring 3.15 ± 0.64 (SD) & and benign thyroid lesion (lymphocytic thyroiditis) showed AgNOR scoring of 1.69 ± 0.10 (SD). Comparative study by other workers also showed significant difference between benign and malignant lesions. There was no significant variation in AgNOR score among the various benign lesions; whereas there was a significantly higher AgNOR score in malignant lesions of thyroid.

Keywords: Thyroid Lesions; Fine Needle Aspiration Cytology (FNAC); Silver Stained Nucleolar Organizer Regions (AgNORs) Technique; Cytological Diagnosis; Nodular Goiter; Papillary Carcinoma; Lymphocytic Thyroiditis

Introduction

Benign thyroid nodules are common and seen in 5-10% of adults and thyroid malignancy is the most common malignancy of endocrine system. Papillary thyroid carcinoma and follicular thyroid carcinoma are often curable and prognosis is good if identified in early stage. Nodular thyroid diseases are indicated by the presence of single or multiple nodules within the thyroid gland. To avoid unnecessary surgery, a thyroid scan, ultrasonography, and fine needle aspiration cytology (FNAC) are used as diagnostic tools to differentiate malignant nodules from benign lesions Cusick et al. [1,2] FNAC technique involves the aspiration of cell samples through a needle attached to a syringe. Needle is introduced into the thyroid swelling and negative pressure is created by the syringe (caliber of the needle generally used is such cases will be G-23). But, in cases of vascular tumors like thyroid; this technique is complicated by aspiration of significant amounts of fresh blood, which compromises the cellular concentration, preservation and interpretation Kate et al. [3,4].

In an attempt to overcome this problem, an alternative method was developed in France, non- aspiration technique or fine needle sampling (FNS). This technique was introduced by Zajdela et al. [5] Followed by Zajdela’s study, various authors attempted this new method of aspiration. Fine needle aspiration (FNA) and fine needle
Various attempts have been made to improve the diagnostic accuracy of FNAC, including morphometric studies, DNA measurement, immunohistochemical, and enzymes techniques for thyroid cancer with varying degrees of success. FNAC provides a rapid, safe and accurate diagnosis of the solitary thyroid nodule Mulazim et al. [7]. A cytological diagnosis of malignancy allows preoperative irradiation and palliative therapy Ravetto et al. [10]. FNAC is of value in metastatic disease, to identify meta static tumors in thyroid. The importance of thyroid FNAC in pregnancy and childhood is well established. Ultrasound has made localization and accurate sampling possible. Impalpable nodule less than 1cm in diameter are commonly detected on ultra sound examination Derlin et al. [11,12]. Repeat FNA can be done in some thyroid lesions when diagnosis cannot be made in first aspiration Dwatkanath et al. [9].

Nucleus is the control centre of cell containing the blue print from which all the components of cell are constructed. This blue print is stored in the form of Deoxyribonucleic acid (DNA) arranged in the form of chromosomes. Nuclei contain dense structures called nucleoli, which are the sites of the ribosomal RNA synthesis and ribosome assembly. The nucleolus plays an essential role in the control of cell proliferation and protein synthesis. Nucleolar organizer regions (NORs) Crocker et al. [13-15] are loops of ribosomal DNA that are transcribed to ribosomal RNA by RNA polymerase and then translated by the ribosome’s into proteins. NORs are located on each of the short arms on acrocentric chromosomes Ghosh et al. [16,17] NORs are segments of DNA closely associated with nucleoli consisting of non-histone proteins, which are argyrophilic, and can be located by staining with silver nitrate [18] NORs are denatured as black-brown spots, they are termed as AgNORs.

Silver staining technique for nucleolar organizer regions (NORs) has been successfully applied to a wide variety of neoplastic lesions on pathological material in order to distinguish benign from malignant lesions [19-21]. In the present study silver staining technique was applied to study AgNOR counts in the neoplastic and non-neoplastic lesions of thyroid. AgNORs were counted in 100 best stained nuclei of FNAC smears under oil immersion microscope (x1000), and mean number of AgNOR per nucleus was calculated. AgNOR counts were compared in benign and malignant lesions of thyroid [22,23].

Materials and Methods

The present study was conducted in the Department of Pathology, Kamineni Institute of Medical Sciences Narketpally, Telangana, India. All the cases of thyroid swelling were referred from the Department of Surgery & ENT of this institute from January-2018 to December-2018. FNA was done in 119 cases and 100 cases were studied for AgNOR count. AgNORs were counted in 100 best stained nuclei of FNA smears under oil immersion microscope (x 1000), and mean number of AgNOR per nucleus was calculated. AgNOR counts were compared in benign and malignant lesions of thyroid [24].

FNAC Technique

Patient was placed in supine position with a pillow under the shoulders, so that the neck was extended. The thyroid gland was fixed between the investigating fingers and the trachea. The contour, surface and consistency of the gland were noted and the target area identified.

Procedure

All the aseptic precautions were observed. The thyroid gland was immobilized with two fingers of the left hand, right hand was used to manipulate. A 23 gauge needle was inserted into target area to the desired depth. Needle was moved back and forth at varying angles to the line of entrance, in order to sample the lesion adequately. Due to the capillary action the material entered the needle [25]. Once the material was seen in the hub of the needle, the needle was removed and pressure applied at the site of puncture. This technique gave an excellent feel of consistency of the tissues and improved precision.

In case of absence of material in the hub of needle, a 20 ml disposable syringe was attached to the needle and negative pressure was applied. When material or blood was noticed in the hub of the needle, the piston of syringe was released; so that the pressure equalizes. Immediately then syringe along with needle was removed. Pressure was applied to the puncture site. The aspirate was expressed onto the surface of clean glass slide. Then the second slide was pressed over the first and the material was gently and evenly spread without crushing. Slides were made from FNA material, one slide was air dried before fixation in 95% methyl alcohol. Rest of the slides were wet fixed in 95% methyl alcohol. One air dried slide was stained with silver nitrate stain and rest of the slides were stained with Hematoxylin & Eosin (H&E) stain 35 and cytomorphological features observed. H&E Stained FNA/FNS smears were studied for cytomorphological features and FNA report was given. Criteria for classifying thyroid lesions was based as per the criteria given by Svante et al. [26].

In the present study all the benign lesions with different diagnosis with respective AgNORs score were compared with the FNA diagnosis of malignant lesions, or follicular neoplasm with their respective AgNOR scores. AgNOR staining was done as described by Bancroft et al. [27] briefly working solution of silver nitrate was
prepared freshly by dissolving five grams of Silver nitrate in 10 ml of distilled water (50% solution) (solution-I). 2% cellulose was dissolved in 100 ml distilled water and 1 % formic acid was added (Solution -II). Two parts of solution one (I) was added to one part of solution two (II) and filtered twice using Whatman’s filter paper.

**Staining Method**

The air-dried slides were stained with freshly prepared silver nitrate working solution for a period of 30 minutes. Incubator was used and temperature of 37 degrees centigrade was maintained till the staining was over. There after washed in distilled water. Silver nitrate stained slide showed nucleolar organizer regions (NORs) and they appeared as intra nuclear black/brown dots under oil immersion lens of microscope(x 1000). They are called AgNORs. AgNORs were counted in 100 best stained nuclei in each case and mean number of AgNOR was calculated per nucleus.

**Inclusion Criteria**

All thyroid swellings subjected to FNA were included in the study.

**Exclusion Criteria**

Patients who had undergone FNA and diagnosed any time before January 2018 and presented for repeat aspiration were excluded from study.

**Results**

In the present study AgNOR staining was used along with assessment of cytomorphological features in FNA of thyroid lesions, 119 cases were studied & cytological diagnosis was given. Out of 119 cases stained with silver nitrate, 100 cases showed cellular foci for nucleolar organizer regions (NORs) (Figures 1-6) and AgNOR score is given in Table 1. In remaining 19 cases AgNOR score was not given due to poor cellularity of the smears. Maximum numbers of lesions were seen in the age group 21 to 30 years (39 cases). Six (6) cases were noticed in males (5.04%) and hundred and thirteen (113) cases in females (94.96%) (Table 2). Benign lesions constituted 108 (90.75%) cases where as malignant lesions were 11 (9.24%). Nodular goiter was the commonest benign lesion (36.97%) and papillary carcinoma of thyroid was the commonest malignant lesion (5.88%) (Table 3). AgNOR score obtained in the present study was compared with the study conducted by other researchers and is presented in Table 4. AgNOR Score ranged from 1.66 to 1.80 for Benign lesions and from 3.07 to 3.15 for Malignant lesions.

**Table 2:** Age & sex wise distribution of thyroid lesions (Cytological diagnosis) n=119.

| Age         | No of cases (%) | Sex/M (%) | Sex/F (%) |
|-------------|-----------------|-----------|-----------|
| 0-10 years  | 1(0.84%)        | Nil       | 1(0.84%)  |
| 11-20 years | 19(15.96%)      | Nil       | 19(15.96%)|
| 21-30 years | 39(32.77%)      | 2(1.68%)  | 37(31.09%)|
| 31-40 years | 29(24.36%)      | Nil       | 29(24.36%)|
| 41-50 years | 16(13.44%)      | 2(1.68%)  | 14(11.76%)|
| 51-60 years | 11(9.24%)       | 2(1.68%)  | 9(7.56%)  |
| 61-70 years | 4(3.36%)        | Nil       | 4(3.36%)  |
| Total       | 119             | 6(5.04%)  | 113(94.96%)|

Note: Maximum No. of lesions were seen in age group 21to30 years. (39 cases).
6 cases were noticed in males (5.04%) & 113 cases in females ( 94.96%).

**Table 3:** Cytological diagnosis of thyroid lesions (n=119).

| FNA Diagnosis                  | Number (%) |
|-------------------------------|------------|
| Colloid Goitre                | 10(8.40%)  |
| Nodular goitre                | 44(36.97%) |
| Hashimoto’s Thyroiditis       | 22(18.48%) |
| Lymphocytic Thyroiditis       | 32(26.89%) |
| Follicular Neoplasm           | 4(3.36%)   |
| Papillary Carcinoma           | 7(5.88%)   |
| Total                         | 119        |

Note: Benign lesions constitute 108(90.75%) cases where as malignant lesions were 11(9.24%) 
Nodular goitre was the commonest benign lesion(36.97%)and papillary carcinoma of thyroid(5.88%) was commonestmalignant lesion.

**Table 4:** AgNOR score (n=100).

| FNA Diagnosis                  | No of Cases (%) | Mean AgNOR |
|-------------------------------|-----------------|------------|
| Colloid Goitre                | 9(9%)           | 1.71(0.54) |
| Nodular goitre                | 36(36%)         | 1.74(0.10) |
| Hashimoto’s Thyroiditis       | 18(18%)         | 1.80(0.11) |
| Lymphocytic Thyroiditis       | 27(27%)         | 1.69(0.10) |
| Follicular Neoplasm           | 3(3%)           | 3.07(0.06) |
| Papillary Carcinoma           | 7(7%)           | 3.15(0.64) |
| Total                         | 100             |

Note: AgNOR Score ranged from 1.66 to 1.80 for benign lesions and from 3.07 to 3.15 for Malignant lesions.
Discussion

Fine needle aspiration (FNA) and fine needle sampling (FNS) of thyroid are safe techniques that cause little or no discomfort to the patient and yield diagnostically significant information [18]. FNS is superior to FNA in vascular organs like thyroid [28,29]. FNS gives better perception of tumor consistency with control of hand. FNS gives better cell yield with little or no hemorrhage. The cytological architecture of thyroid was well preserved [30]. In the present study AgNOR staining was used along with assessment of cytomorphological features in FNA / FNS of thyroid smears to differentiate benign and malignant lesions of thyroid [14,17]. The amount of AgNOR staining reflects the proliferation of a given cell [31]. The number of AgNORs thus reflects nuclear and cellular activity. AgNOR staining technique is simple and can be done alone with the FNA and report of AgNOR score and FNA can be given together. However there was overlapping of cells. Presence of limited single discrete cells caused counting in 100 cells quite tedious and time consuming Sarita Asotra et al. [32] studied 140 cases. There were 100 non-neoplastic and 40 neoplastic cases. Females formed the major group (84.28%). Age ranged from 15 to 82 years.

Maximum number of cases were in the 20-40 years of age. Cytological diagnosis was given in all cases and AgNOR score was given. Higher AgNOR Score was recorded in malignant lesions compared to benign lesions (Table 4). Mehrotra et al. [21] studied cytomorphological features and the value of silver nitrate staining method in distinguishing non neoplastic, benign and malignant neoplasm in 140 cases. Lower AgNOR counts were recorded in cases of thyroiditis (1.37 ± 0.41) whereas the follicular carcinoma had higher AgNOR counts (5.04±0.52). Higher AgNOR counts in malignant lesions were also recorded by Shechtman et al. [33]. In the present study higher AgNOR score was recorded in malignant lesions compared to benign lesions. Mean AgNOR score in lymphocytic thyroiditis was 1.69±0.10 (SD) and mean AgNOR count in papillary carcinoma was 3.15 ±0.64 (SD). The AgNOR score in a similar study by Sarita Asotra et al. [33] recorded higher scores than in the present study for both benign and malignant lesions. However the distinction in the scores between the two groups remained comparable (Table 4). In the case of lymphocytic thyroiditis Sarita et al. [33] have studied 3 cases with a mean AgNOR score of 3.59 where as in the present study there were 27 cases with a mean AgNOR score of 1.69[34-36].

Limitations of Study:

In the present study there was lack of histopathological correlation and long term follow up of the cases, as the current study period was limited. Studying 2 or more smears for AgNOR scores would give better results than the single smear used in the present study [37,38]. As single smear staining with silver nitrate will be time consuming, staining slides in batches of 5 will save cost but would delay reporting.

Conclusion

AgNOR scoring on fine needle aspiration smears is a simple method. It can be combined with routine cytologic stains in the cytological evaluation, to differentiate benign from malignant lesions of thyroid.
