Product decompositions of quasirandom groups and
a Jordan type theorem

N. Nikolov and L. Pyber

Abstract

We first note that a result of Gowers on product-free sets in groups
has an unexpected consequence: If $k$ is the minimal degree of a rep-
resentation of the finite group $G$, then for every subset $B$ of $G$ with
$|B| > |G|/k^3$ we have $B^3 = G$.

We use this to obtain improved versions of recent deep theorems
of Helfgott and of Shalev concerning product decompositions of finite
simple groups, with much simpler proofs.

On the other hand, we prove a version of Jordan’s theorem which
implies that if $k \geq 2$, then $G$ has a proper subgroup of index at most
$c_0 k^2$ for some constant $c_0$, hence a product-free subset of size at least
$|G|/ck$. This answers a question of Gowers.

0 Introduction

Sum-free subsets of abelian groups have been much investigated in the past
40 years. Very recently Green and Ruzsa [GR] have determined the maximal
size of a sum-free subset of any finite abelian group.

A subset $X$ of a not necessarily abelian group $G$ is called product-free if
there are no solutions to $xy = z$ with $x, y, z \in X$. The maximal size $\alpha(G)$ of
a product-free subset of a finite group $G$ has been considered by Babai and
Sós [BS]. For example, they proved that for any soluble group $G$ of order
$n$ we have $\alpha(G) \geq 2n^2$ and asked whether a similar linear bound holds for
arbitrary finite groups.

Note that any non-trivial coset of a subgroup is product-free. In fact, in
1950 (according to [PS, p. 246]) Moser conjectured that the largest product-
free subsets of alternating groups are cosets of maximal subgroups.

Kedlaya [Ke] disproved this, by showing that if a subgroup $H$ has index
$m$ in a group $G$, then one can actually find a set of size $cm^{1/2}|H|$ that is
product-free. Here and below $c$ denotes an absolute constant.
Combining this estimate with the classification of finite simple groups (CFSG) Kedlaya showed that for every finite group $G$ we have $\alpha(G) \geq cn^{\frac{11}{14}}$. He asked whether for every $\varepsilon > 0$ one can obtain a bound of $c(\varepsilon)n^{1-\varepsilon}$.

A negative answer to the above question was obtained very recently by Gowers [Gow]. He showed that for sufficiently large $q$ the group $\Gamma = PSL(2, q)$ has no product-free subsets of size $c|\Gamma|^\varepsilon$. His proof depends on the fact, proved by Frobenius, that every non-trivial representation of $PSL(2, q)$ has degree at least $(q - 1)/2$.

Gowers went on to consider combinatorial properties of finite groups $G$ such that every non-trivial representation of $G$ has degree at least $k$. He calls such groups quasirandom, since this property turned out to be equivalent to several other properties, some of which state that certain associated graphs are quasirandom (see [Gow] for a detailed discussion of quasirandom graphs).

Gowers proved [Gow, p. 22] the following general result on product-free sets of quasirandom groups.

**Proposition 0.** Let $G$ be a group of order $n$, such that the minimal degree of a nontrivial representation is $k$. If $A, B, C$ are three subsets of $G$ such that $|A||B||C| > \frac{n^3}{k}$, then there is a triple $(a, b, c) \in A \times B \times C$ such that $ab = c$. □

The starting point of the present paper is the following surprising consequence.

**Corollary 1.** Let $G$ be a group of order $n$, such that the minimal degree of a representation is $k$. If $A, B, C$ are three subsets of $G$ such that $|A||B||C| > \frac{n^3}{k}$, then we have $A \cdot B \cdot C = G$. In particular, if, say, $|B| > \frac{n}{k^{1/3}}$, then we have $B^3 = G$.

**Proof.** Consider the set $G \setminus AB$. By Proposition 0 the size of this set is strictly less than $|C|$, i.e., we have $|AB| + |C| > |G|$. It follows that for any $g \in G$ the intersection of the sets $AB$ and $gC^{-1}$ is non-empty, which implies $g \in ABC$. □

Applying Corollary to the sets $A, B, C^{-1}$ we see that Proposition 0 and Corollary 1 are in fact equivalent.

Corollary 1, apart from its intrinsic interest, seems to be an extremely useful tool. Recently a number of deep theorems have been obtained concerning product decompositions of simple groups. Corollary 1 can be used to give short and relatively elementary proofs, while improving the results.
It is particularly useful in the case of simple groups of Lie type. For these groups rather strong lower bounds on the minimal degree of a representation are known.

For a (possibly twisted) Lie type \( L \), not \( 2B_2, 2G_2, 2F_4 \) define the rank \( r = r(L) \) to be the untwisted Lie rank of \( L \) (that is, the rank of the ambient simple algebraic group) and for \( L \) of type \( 2B_2, 2G_2, 2F_4 \) define \( r(L) = 1, 1, 2 \) respectively.

It follows from [LS] that there is a constant \( c \) such that for any simple group \( L \) of Lie type of rank \( r \) over \( \mathbb{F}_q \) we have \( k \geq cq^r \) for the minimal degree \( k \) of a representation of \( L \).

For \( L = \text{PSL}(n, q) \) we obtain the following.

**Proposition 2.** Let \( B \) be a subset of \( L \) of size at least \( 2|L|/q^{n-1} \). Then we have \( B^3 = L \).

A similar result in the case of \( \Gamma = \text{PSL}(2, p) \), \( p \) prime, plays an important role in the proof of a recent breakthrough result of Helfgott concerning the diameter of Cayley graphs of \( \Gamma \).

Helfgott [He] showed that for every set of generators \( X \) of \( \Gamma \) every element of \( \Gamma \) can be expressed as a product of at most \( O((\log p)^c) \) elements of \( X \) itself and \( X^{-1} \).

Proposition 2 improves (the easier part of) his Key Proposition [He, p. 2] even for \( \Gamma = \text{PSL}(2, p) \) and implies that in fact every element of \( \Gamma \) can be expressed as a product of at most \( O((\log p)^c) \) elements of \( X \) itself (this improvement also follows from the results in [Ba]).

It is an open problem whether Helfgott’s result extends to \( \text{PSL}(n, p) \). Proposition 2 may be useful in obtaining a positive answer.

As another interesting application we prove the following Waring type theorem. For a group word \( w = w(x_1, \ldots, x_d) \) let \( w(G) \) denote the set of values of \( w \) in \( G \).

**Theorem 3.** Let \( k \geq 1 \) and \( \overline{w} = \{w_1, \ldots, w_k\} \) be a set of non-trivial group words. Let \( L \) be a finite simple group of Lie type of rank \( r \) over the field \( \mathbb{F}_q \) and set \( \overline{w}(L) = w_1(L) \cap \cdots \cap w_k(L) \). Let \( W \) be any subset of \( \overline{w}(L) \) such that \( |W| \geq |\overline{w}(L)|/q^{r/13} \).

There exists a positive integer \( N \) depending only on \( \overline{w} \) such that if \( |L| > N \), then we have \( W^3 = L \). \( \square \)

As the main result of a difficult paper Shalev [Sh] has obtained the same result in the case \( k = 1 \) and \( W = \overline{w}(L) \) (allowing \( L \) to be also an alternating
Combining the methods of that paper with [LSh1] one can prove it for \( W = \mathfrak{w}(L) \) and \( k \) arbitrary. An advantage of our sparse version is that one can impose further restrictions on \( W \). For example one can require that no two elements of \( W \) are inverses of one another or images of one another under Frobenius automorphisms. In addition, (using the first part of Corollary 1) it follows that every element \( g \in L \) is a product \( g = h_1 h_2 h_3 \) of distinct \( h_i \in \mathfrak{w}(L) \). It will be interesting to see if \( h_i \) can be taken to be pairwise noncommuting elements from \( \mathfrak{w}(L) \), or such that \( \langle h_1, h_2, h_3 \rangle = G \); this doesn’t seem to follow immediately from Corollary 1.

Shalev’s proof in [Sh] relies on a whole array of deep results on the character theory of simple groups, developed to estimate the diameters of Cayley graphs of simple groups with respect to conjugacy classes.

Our proof of Theorem 3 is relatively short compared to [Sh] and uses an auxiliary result from [LSh1], see Proposition 1.2 below. This says roughly that for simple groups of Lie type not of type \( A_r \) or \( ^2A_r \) the sets \( \mathfrak{w}(L) \) are “very large”.

For groups of type \( A_r \) and \(^2A_r \) we provide somewhat weaker estimates for \( |\mathfrak{w}(L)| \) which still make Corollary 1 applicable.

It would be most useful to obtain analogues of Corollary 1 for smaller sets \( B \). The following results indicate how far one can go in this direction.

**Theorem 4.** Let \( G \) be a finite linear group of degree \( k \) over the complex field. Then \( G \) has a permutation representation of degree at most \( c_0 k^2 \) with abelian kernel, where \( c_0 < 10^{10} \) is an absolute constant. \( \square \)

The proof of this result relies on the Classification of the finite simple groups (CFSG). As an immediate consequence we obtain the following.

**Corollary 5.** Let \( G \) be a finite group such that \( G \) has an irreducible representation of degree \( k \geq 2 \). Then \( G \) has a proper subgroup \( H \) of index at most \( c_0 k^2 \). \( \square \)

In particular \( H \) is a subset of size at least \( \frac{n}{c_0 k^2} \) in \( G \) which does not even generate \( G \).

As a “partial converse” to Proposition 1.1 Gowers [Gow] proved that if a group \( G \) contains no large product-free subsets, then it is quasirandom. More precisely, he gave an elementary argument showing that if the minimal degree of a representation of \( G \) is \( k \), then \( G \) has a product-free subset of size

\[1\text{We remark that for alternating groups and simple groups of Lie type of bounded rank it was shown later in [LSh1] that in fact one has } \mathfrak{w}(L)^2 = L \text{ if } L \text{ is large enough.}\]
at least $\frac{n}{c^k}$ for some absolute constant $c > 1$. Gowers asked whether this can be improved to $\frac{n}{c^k}$ (for $k \geq 2$). Applying Kedlaya’s result to $H$ as above we see that $G$ has a product-free subset of size at least $\frac{n}{c^k}$ for some constant $c$, i.e. we obtain a positive answer to his question.

Finally, for completeness in the last section we present a simplified version of Gowers’ proof of Proposition 0 in the special case when one of the sets $A$, $B$ or $C$ is symmetric. This case is enough for most of our applications above.

1 Waring type theorems

The main result of [Sh] is the following

**Theorem 1.1.** Let $w \neq 1$ be a group word. Then there exists a positive integer $N = N(w)$ such that for every nonabelian finite simple group $G$ with $|G| \geq N$ we have

$$w(G)^3 = G.$$  

For example, each $g \in G$ can be expressed as a product of three $k$-th powers.

The proof in [Sh] relies on algebraic geometry via [La], the Deligne–Lusztig theory of characters of Chevalley groups and on a recent work on character theoretic zeta functions [LSh2].

In this section we indicate a proof of Theorem 3. It is a generalization of the above theorem for groups of Lie type which does not use such difficult character theoretic tools. We rely instead on some very recent results of Larsen and Shalev. In [LSh1] they give a short proof of the following.

**Proposition 1.2.** Let $k \geq 1$ and $\mathcal{W} = \{w_1, \ldots, w_k\}$ be a set of words. Let $L$ be a finite simple group of Lie type of rank $r$, which is not of type $A_r$ or $2A_r$. There is an absolute constant $c$ and an integer $N = N(\mathcal{W})$ such that if $|L| \geq N$ then we have

$$|\mathcal{W}(L)| \geq c|L|/r.$$  

The proof of Proposition 1.2 relies on algebraic geometry (replacing [La]) and group theoretic arguments. It also applies to groups of type $A_r$ and $2A_r$ for $r$ bounded and in fact to their covering groups $SL(r+1,q)$, $SU(r+1,q)$.

As noted in the introduction, if $L$ is a simple group of Lie type over $\mathbb{F}_q$, then we have $k \geq cq^r$ for the minimal degree $k$ of a representation of $L$. Hence Proposition 1.2 and Corollary 1 immediately imply Theorem 3 if $L$ is not of type $A_r$ or $2A_r$, with $r \geq 1000$, say.

5
For the groups $SL(n, q)$ and $SU(n, q)$ the minimal degree of a representation is at least $\frac{q^{n-1} - 1}{2}$, see [LS]. To complete the proof of Theorem 3 we have to show that for these groups we have

$$\frac{|w(G)|}{q^{\frac{n-1}{2}}} > \frac{|G|}{(q^{n-1} - 1)^{\frac{1}{3}}}$$

if $n$ is large enough. This is achieved below where we prove that $|w(G)|/|G| \geq \gamma n^{-3} q^{-50 - n/4}$ for some constant $\gamma > 0$ depending only on $w$.

Let $G = L(q)$ be a quasisimple group of Lie rank $r$ defined over $\mathbb{F}_q$. A regular semisimple (r.s.) element $g$ of $G$ is one which has distinct eigenvalues (possibly in a field extension of $\mathbb{F}_q$). Therefore $C_G(g)$ is a torus of $G$ and so $|C_G(g)| = (1 + o(1))q^r$. It is well-known that the set of regular semisimple elements of a semisimple connected algebraic group $G$ has complement of strictly smaller dimension than $\dim G$ (see [GL2]). Using this we have

**Lemma 1.3.** Given the type $L$ there is a constant $C$ depending on $L$ such that the cardinality of the r.s. elements of $G$ is at least $(1 - C/q)|G|$. The following proposition is an important ingredient for our proof of Theorem 3.

**Proposition 1.4.** Given $\overline{w} = \{w_1, \ldots, w_k\}$ there is a constant $c > 0$ depending only on $\overline{w}$ such that if $G = SL(4n, q)$, then $|w(G)| > c|G|/(n^3 q^{n-1})$. In fact, $w(G)$ contains at least $cq^{3n}/n^3$ conjugacy classes of regular semisimple elements.

**Proof of Proposition 1.4.** The main idea of the proof is a generalization of some arguments in Section 2 of [LSH1] from the case of $SL(2, q^n)$ to $SL(4, q^n)$:

Consider the inclusion $i : H = SL(4, q^n) \rightarrow SL(4n, q)$ and let $g \in H$ be a semisimple element whose eigenvalues form the multiset $\{a_1, \ldots, a_4\} = A$. Let $F$ be the automorphism $x \mapsto x^q$ of $\mathbb{F}_q$. Since the eigenvalues $a_i$ are roots of the characteristic polynomial of $g$ with coefficients in $\mathbb{F}_{q^n}$ it follows that $A^{F^n}$ is a permutation of $A$.

The eigenvalues of $i(g)$ form the multiset $A, A^F, \ldots, A^{F^{n-1}}$.

**Lemma 1.5.** There are at least $(1 - O(nq^{-n/2}))/|H|$ elements of $g \in H$ such that $i(g)$ is regular semisimple in $G$. 

6
Proof. By Lemma 1.3 the number of elements of $H$ which are not regular semisimple in $H$ is $O(q^{-n})|H|$. So it is enough to consider only regular semisimple elements $g \in H$.

Now, suppose that $g \in H$ is regular semisimple but $i(g) \in G$ is not regular. The eigenvalue multiset of $g \in H$ then consists of 4 distinct elements and has the form

$$A = \bigcup_{i=1}^{s} \{ \alpha_i, \alpha_i^F, \cdots, \alpha_i^{F(k_i-1)n} \},$$

where $4 = k_1 + \cdots + k_s$ is a partition of 4, and $\alpha_i$ is a generator for the finite field $\mathbb{F}_{q^{k_i}}$ over $\mathbb{F}_{q^n}$. In addition, the product of all elements of $A$ should be 1.

Since $i(g)$ is not regular there are two elements $\alpha$ and $\beta$ from $A$ such that $\alpha = \beta^{F_j}$ where $0 < j < n$. Now $\alpha$ and $\beta$ are either from distinct orbits of $F^n$ in $A$, or from the same orbit. In the first case without loss of generality we may assume that $\alpha = \alpha_1$ and $\beta = \alpha_2 = \alpha_1^j$. Then $k_1 = k_2$ and the eigenvalue multiset $A$ of $g$ is then determined by $j$ and the $(s-1)$ eigenvalues $\alpha_i \in \mathbb{F}_{q_{k_i}}$ for $i \neq 2$. Simple calculation shows that the number of possibilities for $A$ (i.e. for the conjugacy class of $g$ in $H = SL(4, q^n)$) is at most $O(nq^{2n})$.

In the second case, if we assume that $\alpha = \alpha_1$ there is a proper divisor $d$ of $k_i n$ such that $\alpha_1 = \alpha_1^{F_d}$, i.e. $\alpha_1 \in \mathbb{F}_{q^d}$. Given $d$, counting the possibilities for $\alpha_1, \ldots, \alpha_s$ under the restriction $\alpha_1 \in \mathbb{F}_{q^d}$ we see that there are $O(q^{3n-k_i n+d}) = O(q^{3n-n/2})$ possible choices for $A$. So in this case, as $d$ ranges over all proper divisors of $n$ there are altogether at most $O(nq^{5n/2})$ conjugacy classes of such $g$.

Combining both cases for all partitions $(k_i)$ of 4 we see that the number of conjugacy classes of regular semisimple elements $g \in H$ such that $i(g)$ is not regular in $SL(4n, q)$ is $O(nq^{3n-n/2})$. This gives the conclusion of the lemma. 

Now by Proposition 8.2 of [LSH] there is a constant $c_0 > 0$ such that $|\pi(H)| > c_0|H|$. Together with Lemma 1.3 this implies that $\pi(H)$ contains at least $c_1 q^{3n}$ conjugacy classes of r.s. elements $g$ such that $i(g)$ is also regular. Here the constant $c_1$ can be taken to be any number in $(0, c_0)$ provided that $n$ is sufficiently large.

Lemma 1.6. Suppose $g^H$ is a conjugacy class of r.s. elements of $H$. There are at most $O(n^3)$ distinct conjugacy classes $h^H$ of $H$ such that $i(g)^G = i(h)^G$. 

Proof. Note that the conjugacy classes of semisimple elements of $SL(n, q)$ are uniquely determined by the multisets of their eigenvalues. Given $g$ with eigenvalue multiset $A$ as above, suppose that $h$ has an eigenvalue multiset $B = \{b_1, \ldots, b_4\}$ and $i(g)^G = i(h)^G$, i.e., $\cup_{j=1}^{n-1} A^{F_j} = \cup_{j=1}^{n-1} B^{F_j}$. This implies that every one of $b_1, b_2, b_3$ can take one of $4n$ given values. Having chosen these three, the fourth one, $b_4$ is then uniquely determined by $\det h = 1$.

With the above lemma we obtain that $i(\overline{w}(H))$ contains at least $cq^{3n}/n^3$ distinct conjugacy classes of r.s. elements of $G$ (where $c$ depends only on $\overline{w}$) and so

$$|\overline{w}(G)| \geq |i(\overline{w}(H))^G| \geq \frac{cq^{3n}}{n^3} \cdot \frac{|G|}{q^{4n-1}} = \frac{c|G|}{n^3q^{n-1}},$$

proving Proposition 1.4.

For general $SL(n, q)$ we have

Proposition 1.7. Given $\overline{w}$ there is a constant $c' > 0$ depending only on $\overline{w}$ and such that if $G = SL(n, q)$ then

$$|\overline{w}(G)| > \frac{c'|G|}{n^3q^{24}+n/4}.$$

Proof. Let $m = \lceil n/4 \rceil$ Consider the embedding $j : SL(4m, q) \rightarrow SL(n, q)$ in the top left corner. By Proposition 1.4 $\overline{w}(H)$ contains $cq^{3m}/m^3$ conjugacy classes of r.s. semisimple elements $g$. Observe that this means that $4m$ of the eigenvalues of $j(g) \in G$ are distinct, and the rest are equal to 1. This easily gives that $|C_G(j(g))| = O(q^{25+4m-1})$ and hence $|\overline{w}(G)| > c' |G|/(n^3q^{m+24})$ for the appropriate $c'$.

The unitary group

When $L = SU(d, q)$ the result we use is

Proposition 1.8. There is a constant $c > 0$ such that

$$|\overline{w}(L)| > \frac{c|L|}{d^3q^{49+d/4}}.$$

Proof. The argument is similar to the case of $SL(n, q)$ above. Let $n \in \mathbb{N}$ be odd. Consider the embedding $i$ of $H = SU(4, q^n)$ inside $G = SU(4n, q)$ defined in the following way: Let $V$ be a 4-dimensional vector space over $\mathbb{F}_q$ equipped with a nondegenerate hermitian form $v : V \times V \rightarrow \mathbb{F}_q$. Consider the form $v' = t \circ v$ where $t = \text{Tr}_{\mathbb{F}_q^2/\mathbb{F}_q}$ is the trace map onto $\mathbb{F}_q$.
Since \( n \) is odd the above map is still hermitian (and nondegenerate). For \( g \in H \) \( i(g) \) is the same transformation \( g \) of \( V \) considered as a vector space over \( \mathbb{F}_q^2 \) with the form \( v' \).

Let \( F \) be the automorphism \( x \mapsto x^q \). If \( g \in H \) is a semisimple element its multiset of four eigenvalues \( A \) satisfies \( A = A - F^n \). The element \( i(g) \in G \) has eigenvalue multiset \( A, A^2, \ldots, A^{2(n-1)} \) and from then on the argument is very much the same: First we prove just as in Lemma 1.5 that the number of elements \( g \in H \) such that \( i(g) \) is not r.s. is \( O(nq^{-n/2}|H|) \). Then, just as in Proposition 1.4 it follows that there is a constant \( e_0 \) such that at least \( e_0q^{3n} \) conjugacy classes of \( H \) consist of elements \( g \in \mathfrak{w}(H) \) such that \( i(g) \) is regular semisimple. Next, at most \( O(n^3) \) such conjugacy classes of \( H \) become conjugate in \( G \) (because for \( i(g)^G = i(h)^G \) we need three eigenvalues of \( h \) to be from \( A^\pm F^j \), \( j = 0, 1, \ldots, n-1 \) and then they determine the last eigenvalue of \( h \)). It follows that \( \mathfrak{w}(G) \) contains at least \( e_1q^{3n}/n^2 \) conjugacy classes of r.s. elements. Finally, considering the embedding of \( G = SU(4n, q) \) in \( L = SU(d, q) \) as a subgroup space (where \( n = 2[(d-4)/8] + 1 \), we see that \( \mathfrak{w}(L) \) contains at least \( e_1q^{3n}/n^2 \) conjugacy classes of elements \( g \) with distinct eigenvalues on a nondegenerate \( 4n \) dimensional subspace \( U \). Any \( h \in C_L(g) \) stabilizes \( U \) and \( U^\perp \) and hence \( |C_L(g)| = O(q^{4n+49}) \). (Note that \( \dim U^\perp = d - 4n \leq 7 \).)

This completes the proof of Theorem 3.

Incidentally we observe the following consequence of Propositions 1.2, 1.7 and 1.8.

**Theorem 1.9.** Given a set of words \( \mathfrak{w} \) and a simple group \( L \) of Lie type, two random elements from \( \mathfrak{w}(L) \) generate \( L \) with probability tending to 1 as \( |L| \to \infty \). In particular a random pair of squares generates \( L \) with probability 1.

This follows easily from the above propositions and a result of Liebeck and Shalev in [LSh3] that the set of pairs \( (a, b) \in L \times L \) which don’t generate \( L \) has size at most \( c|L|^2/P(L) < c|L|^2q^{-r} \).

## 2 Bounds for linear groups

By a classical result of Jordan a finite linear group of degree \( k \) has an abelian normal subgroup \( A \) of index \( j(k) \) for some function \( j(k) \).

Essentially the best elementary estimate for \( j(k) \) is due to Blichfeldt:

\[
j(k) \leq k! 6^{(k-1)\pi(k+1)+1}
\]
where \( \pi(k + 1) \) denotes the number of primes \( \leq k + 1 \) (see [Da]).

Better bounds can be obtained using CFSG. Building on an unpublished work of Weisfeiler, Collins [Co] has recently shown that for \( k \geq 71 \) we have \( j(k) = (k + 1)! \) (see [GL1] for the history of this result).

It is clear that \( G/A \) has an embedding into \( \text{Sym}(j(k)) \). Hence Theorem 4 may be considered as a different type of quantitative version of Jordan’s theorem.

For the proof we need various auxiliary results.

A \( p \)-group \( P \) is said to be of symplectic type if it has no noncyclic characteristic abelian subgroups. The structure of these groups is well understood and is closely related to that of extraspecial groups.

In particular if \( P \) has exponent \( p \) (\( p \) odd), then \( P \) itself is extraspecial, and if it has exponent 4, then \( P \) is either extraspecial or the central product of an extraspecial group and \( \mathbb{Z}_4 \).

We will use the following.

**Proposition 2.1.** Let \( P \) be a \( p \)-group of symplectic type and set \( C = C_{\text{Aut}(P)}(Z(P)) \).

\begin{itemize}
    
    \item[(i)] If \( P \) has exponent \( p \) (\( p \) odd) and order \( p^{2m+1} \), then \( C \) can be embedded in \( \text{Sym}(p^{2m}) \).
    
    \item[(ii)] If \( P \) has exponent 4 and order \( 2^{2m+2} \), then \( C \) can be embedded in \( \text{Sym}(2^{m+2} - 4) \).
    
    \item[(iii)] If \( P \) has exponent 4 and order \( 2^{2m+1} \), then \( C \) can be embedded in \( \text{Sym}(2^{m+1} - 2) \).
\end{itemize}

Hence in all cases \( C \) can be embedded in \( \text{Sym}(4p^{2m}) \).

**Proof.** The structure of the above groups \( P \) and \( C \) is described in [KL, Table 4.6A]. In all cases \( \text{Inn}(P) \) is an elementary abelian minimal normal subgroup of order \( p^{2m} \) in \( C \). Each element of \( C/\text{Inn}(P) \) acts as a nontrivial linear transformation, hence \( \text{Inn}(P) \) is the unique minimal normal subgroup of \( C \).

In case (i) we have \( C/\text{Inn}(P) \cong \text{Sp}(2m,p) \) and moreover by [Gr] the extension splits. Hence \( C \) has a corefree subgroup of index \( p^{2m} \) which implies (i).

In case (ii) \( P \) may be expressed as the central product of \( \mathbb{Z}_4 \) and \( m \) copies of the dihedral group \( D_8 \), \( P = \mathbb{Z}_4 \circ D_8 \circ \cdots \circ D_8 \).

In case (iii) either \( P \) is a central product of \( m \) copies of \( D_8 \) or \( P \) is a central product of \( m - 1 \) copies of \( D_8 \) with the quaternion group \( Q_8 \).
In both cases $C$ acting faithfully on the elements of $P \setminus Z(P)$ provides the required embedding.

For a finite group $G$ we denote by $R_0(G)$ the smallest degree of a non-trivial complex projective representation of $G$. For simple groups $L$ of Lie type strong lower bounds for $R_0(L)$ follow from the work of Landazuri and Seitz [LS] (see [KL] Table 3.3A and [Lüt]). See also [KL] and [CCNPW] for the value of $R_0(L)$ when $L$ is an alternating or sporadic group.

Denote by $P(G)$ the minimal degree of a faithful permutation representation of a group $G$. If $L$ is a simple group with a proper subgroup $H$, then $H$ considered as a subgroup of $\text{Aut}(L)$ is corefree, hence we have

$$P(\text{Aut}(L)) \leq |L : H| |\text{Out}(L)|.$$

When $L$ is of Lie type and $H$ is a parabolic subgroup of $L$ we can improve the above bound as follows: The group $H$ is invariant under the subgroups $D, \Phi \leq \text{Aut}(L)$ of diagonal and field automorphisms of $L$. Then $HD\Phi \leq \text{Aut}(L)$ is a corefree subgroup and hence we have

$$P(\text{Aut}(L)) \leq 6|L : H|$$

if $H$ is parabolic. Sharp bounds for $P(L)$ when $L$ is a classical simple group can be found in [KL] Table 5.2A and they are achieved for parabolic subgroups.

If $L$ is an exceptional group of Lie type one can easily find a maximal parabolic subgroup $P$ of small index. A good lower bound for the order $P$ follows by noting that $|P|$ is divisible by the order of a Borel subgroup of $G$ and also by the order of the Levi factor corresponding to $P$ (see [KL] p. 179–181) for a quick account of these standard facts). See also [Wi] for the detailed structure of many of these maximal subgroups.

Small index subgroups in sporadic simple group can be found in [CCNPW].

In the proof of Theorem 4 we use CFSG via the following.

**Proposition 2.2.** There is an absolute constant $c_0$ such that if $L$ is a non-abelian finite simple group then

$$P(\text{Aut}(L)) \leq c_0 R_0(L)^2.$$

In fact $c_0$ can be taken to be $10^{10}$.

**Proof.** This follows easily from the above mentioned results by inspection. Note that the bound with $c_0 = 10^{10}$ is quite sharp for the Monster simple group.
Recall that a group $H$ is quasisimple if it is a perfect, central extension of a simple group $L$. It is known [Hu] that $\text{Aut}(H)$ is isomorphic to a subgroup of $\text{Aut}(L)$.

The components of a group are its subnormal quasisimple subgroups. The subgroup $E = E(G)$ is generated by the components of $G$. The components of $E(G)$ are exactly the components $C_j$ of $G$ and $\text{Aut}(E)$ permutes the components among themselves [As].

Denote the orbits of $\text{Aut}(E)$ on the components by $B_k$ ($k = 1, 2, \ldots$). Then $B_k$ consists of $t_k$ isomorphic components with central quotient $L_k$. The automorphism group of $B_k$ has a natural embedding into $\text{Aut}(L_k) \wr \text{Sym}(t_k)$. Moreover $\text{Aut}(E)$ has an embedding into $\prod_k \text{Aut}(B_k)$.

These observations imply the following

**Proposition 2.3.**

$$P(\text{Aut}(E)) \leq \sum_j P(\text{Aut}(C_j/Z(C_j)))$$

where the sum is taken over all components $C_j$ of $G$.

The generalised Fitting subgroup of $G$ is $F^*(G) = E(G)F(G)$ (where $F(G)$ is the Fitting subgroup of $G$). The most significant fact about $F^*(G)$ is that $C_G(F^*(G)) \leq F^*(G)$. Denote $C_G(F^*(G)) = Z(F^*(G))$ by $Z$.

The subgroups $E$ and the Sylow subgroups $O_p(G)$ of $F(G)$ are characteristic in $G$ and their product is $F^*(G)$. Hence $G/Z$ has a natural embedding into $\text{Aut}(E) \times \prod_{p/|F(G)|} \text{Aut}(O_p(G))$.

Recall that an irreducible linear group $G \leq GL(V)$ is called imprimitive if the vector space $V$ can be decomposed into a direct sum $V = V_1 \oplus \cdots \oplus V_t$ with $t > 1$, such that every element of $G$ permutes the subspaces $V_i$ among themselves, and $G$ is primitive if no such decomposition exists. By Clifford’s theorem any normal subgroup $N$ of a primitive group is homogeneous, in particular $N$ acts faithfully and irreducibly on some subspace $W$ such that $\dim W$ divides $\dim V$. For primitive linear groups we prove the following more precise version of Theorem 4.

**Theorem 2.4.** Let $G$ be a finite primitive subgroup of $GL(k, \mathbb{C})$. Then $G/Z(G)$ has an embedding into $\text{Sym}(c_0k^2)$.
Proof. It is known [Di] that $Z = Z(G)$ is the unique maximal normal abelian subgroup of $G$, hence $Z = Z(F^*(G))$. Moreover, $Z$ is a group of scalars, hence cyclic.

Let $p$ be a prime such that $O_p(G)$ is not contained in $Z$. Then $O_p(G)$ is the product of the Sylow $p$-subgroup $Z_p$ of $Z$ and an extraspecial $p$-group which is of exponent $p$ in case $p \neq 2$ [LMM, Lemma 1.7]. Therefore the elements of order $p$ (resp. $\leq 4$) in $O_p(G)$ form a characteristic subgroup $R_p$ of $G$ of symplectic type and $O_p(G) = Z_p \cdot R_p$.

By the remarks preceding the theorem $G/Z$ has a natural embedding into $\text{Aut}(E) \times \prod_p \text{Aut}(O_p(G))$. Since conjugation by elements of $G$ stabilizes $R_p$ and fixes $Z_p$ elementwise we actually have an embedding of $G/Z$ into $\text{Aut}(E) \times \prod_p C_{\text{Aut}(R_p)}(Z(R_p))$, where the product is taken over all primes $p$ such that $O_p(G) \neq Z_p$.

Consider the normal subgroup $N = E \cdot \prod_p R_p$ of $G$. The group $N$ may be considered as an irreducible subgroup of $GL(W)$ for some $W$ where $\dim(W)$ divides $k$. $N$ is a central product of the symplectic type groups $R_p$ and the components $C_i$ of $G$ [As]. Hence there is a decomposition of $W$ into the tensor product of spaces $\{W_p\}$ and $\{W_i\}$ such that $W_p$ is an irreducible $R_p$-module for all $p$ and $W_i$ is an irreducible $C_i$-module for all $i$ [Gor, 3.7.1 and 3.7.2].

It is clear that $\dim(W_i) \geq R_0(C_i/Z(C_i))$. We have

$$k \geq \prod_p \dim(W_p) \cdot \prod_i \dim(W_i).$$

Moreover, if $R_p$ has order $p^{2m_p+1}$ or $p^{2m_p+2}$, then $\dim(W_p) = p^{m_p}$ [Gor, 5.5.5]. Hence we have $k \geq \prod_p p^{m_p} \cdot \prod_i R_0(C_i/Z(C_i))$ which gives

$$\sum_p p^{2m_p} + \sum_i R_0(C_i/Z(C_i))^2 \leq k^2.$$

But $G/Z$ has a faithful permutation representation of degree at most

$$\sum_p P(C_{\text{Aut}(R_p)}(Z(R_p))) + P(\text{Aut}(E)) \leq$$

$$\leq c_0 \left( \sum_p p^{2m_p} + \sum_i R_0(C_i/Z(C_i))^2 \right) \leq c_0 k^2$$

using Propositions 2.1, 2.2 and 2.3. Our statement follows. □
The end of the proof of of Theorem 4. If \( G \leq GL(k, \mathbb{C}) \) is irreducible but imprimitive, then it can be embedded into a wreath product \( G_1 \wr T \) where \( G_1 \) is a primitive subgroup of \( GL(k_0, \mathbb{C}) \), \( T \) is a transitive subgroup of \( \text{Sym}(t) \) and \( tk_0 = k \) [Sup]. Now \( A = Z(G_1)^t \) is an abelian normal subgroup of \( G_1 \wr T \).

We have \( \frac{G_1 A}{A} \leq \frac{G_1 \wr T}{A} \) and by Theorem 2.4 \( \frac{G_1 \wr T}{A} \) has an embedding into \( \text{Sym}(c_0 k^2 t) \). Hence \( \frac{G_1}{G_1 A} \) has an embedding into \( \text{Sym}(c_0 k^2) \).

Finally, if \( G \leq GL(k, \mathbb{C}) = GL(V) \) (with \( V = \mathbb{C}^k \)) is an arbitrary finite linear group then \( G \) is completely reducible. Hence it embeds into a direct product \( \prod_j GL(V_j) \) where \( V = \oplus_j V_j \) is a decomposition of \( V \) into irreducible \( \mathbb{C}G \)-modules. Let \( k_j = \dim_{\mathbb{C}} V_j \), so that \( \sum_j k_j = k \). Our group \( G \) acts irreducibly on each \( V_j \) and so by the argument above we find a subgroup \( A_j \leq G \) such that its image in \( GL(V_j) \) is abelian and \( G/A_j \) embeds in \( \text{Sym}(c_0 k_j^2) \). Take \( A = \cap_j A_j \). It follows that \( A \) is abelian and \( G/A \) embeds in \( \text{Sym}(\sum_j c_0 k_j^2) \leq \text{Sym}(c_0 k^2) \). Theorem 4 follows.

By a result of Easdown and Praeger [EP] if \( G \) is a subgroup of \( \text{Sym}(t) \), then \( G/\text{Sol}(G) \) can also be embedded into \( \text{Sym}(t) \) (where \( \text{Sol}(G) \) is the soluble radical of \( G \)). Hence Theorem 4 has the following immediate consequence

**Corollary 2.5.** Let \( G \) be a finite linear group of degree \( k \). Then \( G/\text{Sol}(G) \) has an embedding into \( \text{Sym}(c_0 k^2) \).

In particular \( G/\text{Sol}(G) \) is a linear group of degree at most \( c_0 k^2 \).

**Question 2.6.** Suppose \( G \) is a finite linear group of degree \( k \). Is it true that \( G/F(G) \) embeds in \( \text{Sym}(ck^2) \) for some constant \( c \)? What about \( G/\text{Frat}(G) \)?

### 3 Additional remarks

Following [Gow] let us put some of the results in this paper into a more general context.

If the minimal degree of a representation of a group \( G \) is at least 2, then it is perfect (i.e. it is equal to its commutator subgroup). Hence it is reasonable to assume that a quasirandom group is perfect. For diverse examples of such groups see [HP].

**Theorem 3.1.** Let \( G \) be a perfect group of order \( n \). Then the following statements are polynomially equivalent, in the sense that if one statement holds for a constant \( c \), then all others hold with constants that are bounded by a positive power of \( c \).
(i) Every representation of $G$ has degree at least $c_1$.

(ii) Any product-free subset of $G$ has size at most $\frac{n}{c_2}$.

(iii) For any subset $B$ of size at least $\frac{n}{c_3}$ we have $B^3 = G$.

(iv) Every proper subgroup of $G$ has index at least $c_4$.

Proof. (i) $\implies$ (ii) follows from Proposition 0 (due to Gowers).

(i) $\implies$ (iii) follows from Corollary 1.

(iv) is an easy consequence of either (ii) or (iii).

(iv) $\implies$ (i) follows from Theorem 4. $\square$

Finally, let us point out an application of Corollary 1 to permutation groups. By a deep result of Fulman and Guralnick [FG] if $G$ is a simple group acting transitively on a set $X$ then the proportion of fixed point-free permutations in $G$ is at least $\delta$ for some absolute constant $\delta > 0$. This implies that if $G$ is large enough, then each element of $G$ is a product of three fixed point-free permutations.

4 Appendix: a short proof of a special case of Proposition 0

In this section we will give a short version of Gowers’ proof of Proposition 0 in the case when one of the sets $A, B, C$ is symmetric. This case is enough for most of the applications above. We stress that we don’t claim originality: certainly all the elements of the argument below are already present in Gowers’ proof in [Gow]. We believe that it’s worth presenting a simplified version which can fit in one page.

Proof: Suppose $A, B, C$ are three subsets of $G$ one of which coincides with its inverse and such that $|A||B||C| > n^3/k$. We have to show that the equation $ab = c$ has a solution with $a \in A, b \in B$ and $c \in C$. By cyclically permuting and inverting some of $A, B, C$ we may assume without loss of generality that $B = B^{-1}$ is the symmetric set.

Let $V = CG$ be the group algebra over $\mathbb{C}$ considered as a complex vector space with basis $G$. We will consider $V$ as a left $G$-module equipped the standard Hermitian inner product (so the elements $g$ of $G \subset V$ form an orthonormal basis of $V$).

Let $X = (x_{g,h})$ be the $n$ by $n$ matrix labelled by $g, h \in G$ such that $x_{g,h} = 0$ if $h^{-1}g \notin B$ and $x_{g,h} = 1$ otherwise. Then $X$ is a real symmetric
matrix defining a linear map $X \in \text{End}_C V$. For each $u \in G \subset V$ we have $Xu = \sum_{b \in B} ub$ which shows that $X$ is in fact a $G$-module endomorphism, i.e. $Xg\mathbf{v} = gX\mathbf{v}$ for all $g \in G$ and $\mathbf{v} \in V$.

Note that every row and column sum of $X$ is $|B|$, hence $\lambda_1 = |B|$ is an eigenvalue of $X$ with eigenvector $e = \sum_{g \in G} g \in V$. Let $I = e^\perp$ be the augmentation ideal of $V$. It is both $X$ and $G$-invariant and clearly doesn’t have $G$-invariant vectors.

Now, since $X$ is symmetric it has real eigenvalues. Let $\lambda \in \mathbb{R}$ be an eigenvalue of $X$ on $I$ with eigenspace $V_\lambda$. Since $X$ is a $G$-endomorphism it follows that $V_\lambda$ is a nontrivial $G$-module and hence $\dim V_\lambda \geq k$.

The eigenvalues of $X^2$ are exactly the squares of the eigenvalues of $X$ with the same multiplicities. Thus we have that $tr(X^2) \geq k\lambda^2$. But $tr(X^2) = tr(X^t X)$ is exactly the sum of all entries of $X$ which is $n|B|$. It follows that $\lambda^2 \leq n|B|/k$ holds for all eigenvalues $\lambda$ of $X$ on $I$ and therefore

$$|X\mathbf{v}|^2 \leq \frac{n|B|}{k}|\mathbf{v}|^2 \text{ for all } \mathbf{v} \in I.$$  \hfill (1)

Let $\mathbf{v} = n \sum_{g \in A} g \in V$. We can write $\mathbf{v} = \mathbf{v}_1 + \mathbf{v}_2$ where $\mathbf{v}_1 = |A|e$ and $\mathbf{v}_2 \in I$ with $|\mathbf{v}_2|^2 = |A|n(n - |A|) < n^2|A|$. Assuming that $ab = c$ has no solution $a \in A, b \in B, c \in C$ we deduce from the definition of $X$ that $X\mathbf{v} \in \sum_{g \in G \setminus C} Cg$. However

$$X\mathbf{v} = X\mathbf{v}_1 + X\mathbf{v}_2 = |B||A|e + X\mathbf{v}_2$$

and it follows that the vector $X\mathbf{v}_2$ has coordinates equal to $-|B||A|$ in at least $|C|$ positions, so $|X\mathbf{v}_2|^2 \geq |C||A|^2|B|^2$. On the other hand by (1)

$$|C||A|^2|B|^2 \leq |X\mathbf{v}_2|^2 \leq \frac{n|B|}{k}|\mathbf{v}_2|^2 \leq \frac{n|B|}{k}n^2|A|$$

which implies $|A||B||C| \leq n^3/k$ and this contradicts the starting assumptions. Hence $ab = c$ has a solution as stated in the Proposition.
