Key words: Lignan, manassantin B, Epstein Barr virus (EBV), lytic replication, mTORC2 inhibitor, kinase signaling, phosphoinositide 3-kinase (PI3K), protein kinase C (PKC)

ABSTRACT

Lytic replication of Epstein–Barr virus (EBV) is not only essential for its cell-to-cell spread and host-to-host transmission, but also contributes to EBV-induced oncogenesis. Thus, blocking EBV lytic replication could be a strategy for managing EBV-associated diseases. Previously we identified a series of natural lignans isolated from the roots of Saururus chinensis (Asian lizard’s tail) that efficiently blocks EBV lytic replication and virion production with low cytotoxicity. In the current study, we attempted to elucidate the molecular mechanism by which these lignans inhibit EBV lytic replication. We found that a representative compound, CSC27 (manassantin B), inhibits EBV lytic replication by suppressing the expression of EBV immediate-early gene BZLF1 via disruption of AP-1 signal transduction. Further analysis revealed that manassantin B specifically blocks mTOR complex 2 (mTORC2)-mediated phosphorylation of AKT Ser/Thr protein kinase at Ser-473 and protein kinase Cα (PKCα) at Ser-657. Using phosphoinositide 3-kinase (PI3K)-AKT-specific inhibitors for kinase mapping and shRNA-mediated gene silencing, we validated that manassantin B abrogates EBV lytic replication by inhibiting mTORC2 activity and thereby blocking the mTORC2–PKC/AKT signaling pathway. These results suggest that mTORC2 may have utility as an antiviral drug target against EBV infections and also reveal that manassantin B has potential therapeutic value for managing cancers that depend on mTORC2 signaling for survival.

Epstein–Barr virus (EBV) ubiquitously infects more than 90% of the population worldwide, and is also an etiological agent of several human diseases and malignancies (1-2). Like other herpesviruses, EBV life cycle consists of two phases, latent and lytic. When EBV infects memory B-lymphocytes, it establishes latent infection by default and expresses a few latent
genes to maintain latent infection (3-4). Establishment of latency is a viral strategy to avoid host immune surveillance for lifetime persistent infection. When latent EBV is reactivated in response to physiological stimuli or chemical assault, lytic replication occurs where the virus expresses almost all the genes in its genome, replicates its genomic DNA and produces progeny viral particles releasing from cells. EBV Lytic replication initiates at activation of viral immediate-early genes (ZTA and RTA) and proceeds as almost all viral genes are expressed in a cascade fashion that leads to production of progeny virions (5). Lytic replication is essential for cell-to-cell spread as well as host-to-host transmission of the virus. In addition, increasing evidence indicate that EBV lytic replication also contributes to viral pathogenesis and oncogenesis. (i) EBV lytic replication is crucial for efficient dissemination to the sites of disease. (ii) The presence of low numbers of EBV lytically infected cells could enhance tumor growth through the release of growth factors and immunosuppressive cytokines (6-8). (iii) Elevated antibody titers against EBV lytic antigens and increased viral DNA load in serum/plasma are directly correlated with advanced cancer stages, poor prognosis or tumor recurrence in nasopharyngeal carcinoma (NPC), Hodgkin disease and Burkitt’s lymphoma (9). (iv) EBV lytic replication is directly linked to chronic active EBV infection (CAEBV) and oral hairy leukoplaikia (10, 11). (v) EBV lytic genes BZLF1, BGLF4 and BGLF5 can induce genome instability (12) and other lytic gene products such as LF1, LF2, LF3, BLF1, BALF4 and BHLF1, are detected in tumor biopsies (13-15). Therefore, EBV lytic life cycle contributes to EBV-induced oncogenesis and inhibition of EBV lytic replication can be a strategy for treatment of EBV-associated malignancies.

Reactivation of EBV can be initiated when B cells differentiated into plasma following B cell receptor stimulation by antigen (16). In cell culture system, EBV lytic life cycle can be induced by certain chemicals such as 12-O-Tetradecanoyl-phorbol-13-acetate (TPA) and sodium butyrate (17). These findings informed that host cell signal transduction and epigenetic regulation control the switch of the virus between latency and lytic replication. TPA is found to trigger EBV reactivation cascade through activating protein kinase C (PKC), leading to stimulation of the mitogen-activated protein kinase (MAPK)/extracellular signal-regulated kinase (ERK) pathway (18, 19). As a consequence of the activation of the pathway, c-Fos is accumulated and c-Jun is phosphorylated, leading to the formation of an active AP-1 complex on the ZTA promoter, activation of the gene of EBV immediate-early transcriptional activator ZTA, and initiation of the lytic cascade of EBV (20). In B cell receptor-mediated EBV activation, PI3K-AKT-activated bZip transcription factors (ATF/c-Jun/CREB) also bind to the ZII domain and activate the BZLF1 promoter (21).

PI3K/mTOR signaling is a chief mechanism for controlling cell proliferation, survival and metabolism (22). mTOR exists in two different complexes, mTOR complex 1 (mTORC1) and mTOR complex 2 (mTORC2). In mTORC1, mTOR is associated with Raptor, PRAS40, and mLST8/GβL (23), while in mTORC2, mTOR complexes with two unique regulatory proteins named Rictor and Sin1 in addition to mLST8/GβL, PROTOR/PRR5 and DEPTOR (24-27). mTORC1 is highly sensitive to rapamycin, whereas mTORC2 is insensitive to short-term treatment of rapamycin. mTORC1 and mTORC2 participate in different pathways and recognize distinct substrates. mTORC1 regulates cell growth by controlling the activity of the S6 kinases 1 (S6K1) and the eIF-4E-binding protein 1 (4E-BP1) (28), while mTORC2 modulates cell survival, growth, proliferation and metabolism through controlling the phosphorylation of AKT Ser473 (29). Previous studies showed that inhibition of mTORC1 by rapamycin inhibits EBV and KSHV lytic replication (30, 31). In addition, EBV in turn is able to activate or manipulate PI3K/mTOR signaling, which is associated with oncogenesis. PI3K/mTOR is activated in EBV-positive posttransplant lymphoproliferative diseases (PTLD), Hodgkin lymphoma, NPC and gastric carcinoma (32). In the current study, we found that EBV reactivation is dependent on mTORC2 and inhibition of mTORC2 function by a potential mTORC2 inhibitor, CSC27 (manassantin B), blocks EBV...
switch from latency to lytic replication. Manassantin B inhibits mTORC2 phosphorylation of AKT and PKCα and, as a consequence, blocks EBV lytic replication.

Results

Manassantin B blocks EBV lytic replication through suppressing ZTA-initiated reactivation cascade

In our previous work, we identified a series of natural lignans isolated from the roots of *Saururus chinensis* and showed that they efficiently block EBV lytic replication with low cytotoxicity (33). To understand the mechanism underlying their antiviral activities, a representative compound among these lignans, CSC27 (Manassantin B, a dineolignan), was chosen for further investigation based on its antiviral potency (Fig. 1A). The effect of manassantin B on EBV lytic replication was analyzed using P3HR1 cells, an EBV latently infected Burkitt lymphoma cells line. P3HR1 cells were induced for reactivation with TPA and sodium butyrate (NaB). Three hours post-induction, the cells were exposed to manassantin B in a wide range of concentrations. Intracellular viral genomic DNA was determined at 48 h post-induction. Encapsidated viral DNA was measured for released virions in the media 5 days post-induction. The half-maximal DNA replication inhibitory concentration (IC$_{50}$) and the half-maximal antiviral effective concentration (EC$_{50}$) of manassantin B were determined from the dose-response curves of the intracellular DNA and extracellular virion to be 1.72 and 0.5 μM, respectively (Fig 1B). The cytotoxicity of the compound was assessed using trypan blue exclusion method for cell viability at 48 h and the 50% cytotoxic concentration (CC$_{50}$) was determined to be >50 μM, leading to a selectivity index (SI = CC$_{50}$/EC$_{50}$) of >100. In addition, the antiviral property of manassantin B was also examined in EBV-carrying Akata-BX1 cells in which EBV reactivation was induced by anti-IgG treatment. Result showed that manassantin B inhibited EBV lytic DNA replication and virion production with IC$_{50}$ of 12.96 μM and EC$_{50}$ of 3.06 μM in Akata-BX1 cells (Fig. 1C).

Cytotoxicity of manassantin B to primary lymphocytes was assessed with human peripheral blood mononuclear cells (PBMCs) after 48 h treatment and result demonstrated low cytotoxicity of manassantin B to primary lymphocytes (Fig. 1D).

Transition from latency to lytic state is controlled by two viral transcription factors, namely ZTA and RTA, encoded by BZLF1 and BRLF1. Both ZTA and RTA are essential for viral lytic gene expression and ori-Lyt-dependent DNA replication. The expression of BZLF1 and BRLF1 in induced P3HR-1 cells was determined 48 h post-treatment by qRT-PCR and Western analysis. Results showed significant reductions of both BZLF1 and BRLF1 gene expression in the cells treated with manassantin B in both mRNA and protein levels (ZTA) in a dose dependent manner (Fig. 1E and 1F). As a consequence, the expression of downstream gene, EA-D protein, was also reduced (Fig. 1F). We conclude that Manassantin B inhibits EBV lytic replication through blocking ZTA and RTA-initiated viral reactivation cascade.

Manassantin B inhibits AP-1 signaling pathway

EBV reactivation can be initiated through activating protein kinase C (PKC). As a consequence, c-Fos is accumulated and c-Jun is phosphorylated, leading to the formation of an active AP-1 complex on the ZII domain of the BZLF1 promoter and activation of ZTA gene (20). In addition, other cellular transcription factors such as CREB and ATF are also reportedly associated with the promoter in responsive to PI3K-AKT signaling (21). We asked if manassantin B inhibits EBV ZTA activation by disrupting the AP-1 signaling pathway. To this end, we first employed an electrophoretic mobility shift assay (EMSA) to study the effects of the lignan on the AP-1 DNA binding property. Two double-stranded DNA fragments, one containing a consensus AP-1 binding motif and the other harboring the ZII element of the ZTA promoter, were reacted with the nuclear extract of TPA-induced P3HR1 cells that have been treated with manassantin B in various concentrations. Result showed that a DNA-protein complex was detected with the
AP-1 binding oligonucleotide and the binding was reduced with the extracts of the cells treated with manassantin B (Fig. 2A). Similarly, a DNA-protein complex that appeared only with TPA-induced P3HR1 nuclear extract on the ZII element was also diminished in response to manassantin B in a dose-dependent manner (Fig. 2B), indicating that manassantin B prevents TPA-induced transcription factor, (AP-1 or CREB/c-Jun/ATF), from binding to the ZTA promoter. However, manassantin B did not block the transcription factors in the nuclear extract of non-manassantin B-treated cells binding to AP-1 responsive promoters (Fig. 2C and D), suggesting that manassantin B acts at the pathway upstream of AP-1 activation rather than blocking activated AP-1 binding to DNA. Second, the effect of manassantin B on the transcription activity of AP-1-responsive promoter was analyzed using a promoter-reporter assay. 293T cells were transfected with the AP-1 promoter-luciferase reporter plasmids. Six hours post-transfection, cells were treated with TPA to activate AP-1 signaling. manassantin B in different concentrations was added into the cell culture. The activation of the AP-1-responsive promoter in the absence and presence of manassantin B was measured through the luciferase activities 36 h post-induction. manassantin B was found to be able to block TPA-induced transcription activity of the AP-1-responsive promoter in a dose-dependent manner (Fig. 2E). Taken together, manassantin B inhibits the AP-1 signaling pathway upstream of ZTA, therefore blocking EBV reactivation.

**Kinase mapping: mTOR is required for EBV lytic replication**

In order to identify the target of manassantin B, we continued to trace upstream pathways that are responsible for EBV lytic replication and targeted by manassantin B. PI3K/mTOR and Ras-ERK pathway are two main upstream pathways of AP-1 transduction signaling (34, 35). To understand if these two pathways are involved in EBV reactivation in P3HR1 cells, we employed a whole panel of pharmacological inhibitors of the PI3K-mTOR and ERK pathways for a kinase mapping. The effect of each inhibitor on EBV lytic DNA replication was determined and results showed that the inhibitors to ERK (U0126), PI3K subunits (LY294002, HS173, TGX221, AS252424 CAL-101) and AKT1/2/3 (AT7867) in the concentrations of 10 × their IC50 exhibited little effects on EBV lytic replication. In contrast, mTORC1 inhibitor Rapamycin gave a moderate inhibition and PI3K/mTOR dual inhibitor BEZ235 led to an efficient inhibition of EBV DNA synthesis (Fig. 3A and B). The cytotoxicity of these inhibitors to P3HR-1 cells in these concentrations was determined (Fig. 3C). Furthermore, the effects of rapamycin and BEZ235 in a wide range of concentration on EBV ZTA expression and viral DNA replication were further examined. Rapamycin exhibited partial inhibition on ZTA expression and EBV DNA replication even at the concentration of 1000 × IC50 (Fig. 3E). In contrast, BEZ235 were able to block ZTA expression and EBV DNA replication in P3HR-1 cells (Fig. 3F).

**Manassantin B inhibits mTORC2, AKT and PKC signaling**

Given that among the signal transduction pathways that control AP-1 pathway, mTOR signaling is required for EBV reactivation, we wondered if manassantin B inhibits EBV lytic replication by targeting mTOR signaling. mTOR assembles into two distinct complexes, designated mTORC1 and mTORC2. To gain insights into how manassantin B acts on mTOR pathways, we examined the effect of manassantin B on activation status of the components in mTOR pathways, including AKT, PKC, MEK, ERK and p70S6K using Western analysis 24 h post-induction. AKT activation is tightly controlled by PI3K-mTOR signaling and involves the phosphorylation of Thr-308 in the activation loop or the phosphorylation of Ser-473 in the hydrophobic motif. As shown in Fig. 4, manassantin B specifically blocked the phosphorylation of AKT at Ser-473 but not Thr-308. It is known that phosphorylation of Thr-308 residue in AKT is accomplished by PDK1, while phosphorylation of Ser-473 residue is mediated by mTORC2 (29). Furthermore, phosphorylation of another mTORC2 substrate, PKCa was also inhibited in the presence of manassantin B. In contrast, manassantin B...
showed little effect on mTORC1 activity as the phosphorylation of p70S6K was not decreased or even slightly increased by this lignan. Therefore, manassantin B appears to target mTORC2 and inhibit its kinase activity.

The ERK1/2 are ubiquitous Ser/Thr kinases that phosphorylate hundreds of substrates. manassantin B inhibits the phosphorylation of ERK1/2. However, the phosphorylation of MEK1/2 was not affected by manassantin B.

As the end effector of the signal transduction, the phosphorylation of AP-1 (c-Jun) in response to manassantin B treatment was examined. Result showed that the phosphorylation of c-Jun at Ser73 increased in the cells induced with TPA/Butyrate and the induced phosphorylation of c-Jun was inhibited in the presence of manassantin B in a dose dependent manner (Fig. 4).

**Knockdown of mTORC2 completely blocks EBV lytic replication**

To further confirm that mTORC2 is critically required for EBV lytic replication and serves as the target of manassantin B, we silenced the expression of the genes for mTOR, Raptor and Rictor using an shRNA knockdown approach. mTOR is shared component of mTORC1 and mTORC2, while Raptor and Rictor are specific components of mTORC1 and mTORC2, respectively. Knockdown of mTOR, which destroyed both mTORC1 and mTORC2, resulted in completely shutdown of ZTA expression (Fig. 5A), EBV lytic DNA replication (Fig. 5D) and virion production in TPA-induced P3HR1 cells (Fig. 5E). Silencing Rictor, which down-regulates mTORC2, also led to dramatic reduction in ZTA expression (Fig. 5B), viral DNA replication (Fig. 5D) and virion production (Fig. 5E). In contrast, knockdown of Raptor expression, which down-regulates mTORC1, only reduced ZTA expression to a certain extent (Fig. 5C) and led to partial inhibition of viral DNA replication (Fig. 5D) and virion production (Fig. 5E). These results, together with manassantin B inhibiting the phosphorylation of Akt-473 and PKCα-657, led to the conclusion that mTORC2 is crucial for EBV lytic replication and manassantin B blocks the EBV reactivation through inhibiting mTORC2 signaling. A model for the function of mTORC2 in EBV lytic replication and action of manassantin B (CSC27) is illustrated in Fig. 6.

**Discussion**

A class of lignans isolated from the roots of *Saururus chinensis* were found to be able to effectively block EBV lytic replication (33). In the current study, we investigated the pharmacological property and antiviral mechanism of a representative compound, namely manassantin B (CSC27). The study showed that manassantin B blocks EBV reactivation via preventing viral switch gene ZTA from being activated by cellular signaling pathways. Interestingly, manassantin B targets and disrupts mTOR signaling to achieve the inhibitory effect on EBV reactivation. Revelation of the pharmacology of manassantin B paved the way for exploring application value of this natural lignan in antiviral drug development. Our findings have shown additional salient features as follows.

(i) This study demonstrated essential roles of mTORC2 signaling in EBV reactivation. EBV can be induced to enter lytic replication by either phorbol ester (TPA) treatment or B cell receptor engagement at the B cell surface (17, 36-37). The current study revealed the involvement of mTORC2 in TPA-mediated EBV lytic replication, which can be blocked by manassantin B (Fig. 1B). We also showed that manassantin B can inhibit anti-IgG-induced EBV lytic replication in Akata cells (Fig. 1C), suggesting that both TPA and B cell receptor engagement-mediated EBV reactivation are likely to share or merge into the same pathway – mTORC2 signaling, and ultimately lead to EBV lytic replication. It has been reported that B cell receptor-mediated EBV lytic replication in Akata cells is regulated by mTORC2 (38). Therefore, the study on manassantin B pharmacology revealed a crucial role of mTORC2 signaling in EBV lytic replication as follows. (i) Stimuli activate mTORC2 that phosphorylates AKT at Ser473 and PKCα at Ser657. (ii) Active PKC–AP-1 signaling leads to activation of ZTA and RTA, which initiate EBV lytic replication cascade (Fig. 6). On the other side, manassantin B inhibits mTORC2 kinase activity and blocks...
the mTORC2–PKC–AP-1–ZTA pathway, therefore halting the EBV reactivation from latency.

(ii) The findings that the mTORC2–PKC–AP-1 axis is absolutely required for EBV reactivation and that manassantin B can block EBV reactivation validated mTORC2 as an effective drug target for EBV associated diseases. EBV is an important pathogen responsible for a number of human diseases and cancers. Although much of the EBV-induced pathology has been attributed to viral latency, the importance of EBV lytic replication in viral pathogenicity has been increasingly recognized. Evidence is emerging that reactivation of lytic virus and the lytic activator protein ZTA are associated with tumorigenesis and autoimmune diseases (13, 14, 39, 40). EBV lytic replication is directly linked to chronic active EBV infection (CAEBV), oral hairy leukoplakia in immunosuppressed individuals and an increased risk of EBV-associated nasopharyngeal carcinoma (41-46). Therefore, inhibition of EBV lytic replication may be a strategy for treatment of some EBV-associated diseases. Although a few drugs have been developed against alpha- and beta-herpesviruses (47, 48), there are no effective drugs available to treat gamma-herpesvirus (KSHV and EBV) infection. Therefore, efficacious drugs against EBV are very much needed. Identification of natural lignin Manassantin B as an effective antiviral agent that inhibits EBV reactivation with minimal cytotoxicity provides a candidate compound or lead for further development aiming to a new drug to treat EBV-associated diseases.

(iii) mTOR signaling is known as a master regulator of homeostasis, which controls most anabolic and catabolic processes in response to nutrients and growth factors. Two distinct complexes, mTORC1 and mTORC2, correspond two major branches of signal output. mTORC1 has been well characterized in terms of its structure, regulation and function, while mTORC2 is less studied. mTOR has been a validated drug target for cancer treatment. Rapamycin (mTORC1 inhibitor) and derivatives was approved for treatment of certain cancers but have been less successful than anticipated (22). Several PI3K/mTOR dual inhibitors, such as NVP-BEZ235 and VS-5584, are under clinical trial for cancer therapy including lymphoma treatment (49, 50). These drugs have also shown some promise in preclinical and early clinical trial data but have raised concerns over dose-limiting toxicities (22). Deregulation of mTORC2, particularly hyperactivation, has been observed in many types of human cancers (51, 52). Recent studies in cancer biology indicate that mTORC2 activity is essential for the transformation and vitality of a number of cancer cell types, but is less essential in normal cells (53, 54, 55). Thus, mTORC2 specific inhibitor have special value for cancer treatment. Our recent study showed that mTORC2 is involved in nasopharyngeal carcinoma (NPC) cancer stem cells formation and manassantin B is able to inhibit NPC growth in a xenograft mouse model (unpublished data). Thus, manassantin B exhibits a unique advantage as an mTORC2 inhibitor to treat EBV-associated cancers by targeting multiple layers of pathogenesis, i.e. EBV reactivation and tumorigenesis and exhibiting low cytotoxicity.

Experimental Procedures

Cell culture

P3HR-1 cells, an EBV-positive Burkitt’s lymphoma cell line were maintained in RPMI1640 medium supplemented with 5% fetal bovine serum (FBS, Gibco-BRL). Akata-BX1 cells that carry a recombinant EBV were cultured in RPMI1640 medium supplemented with 10% FBS. Peripheral blood mononuclear cells (PBMCs) were cultured in RPMI1640 medium supplemented with 10% FBS. The PBMCs were isolated from human peripheral blood buffy coat samples of healthy volunteers, obtained from Guangzhou Blood Centre. Human embryonic kidney HEK293T cells were purchased from American Type Culture Collection (ATCC) and cultured in Dulbecco’s modified Eagle’s medium (DMEM) supplemented with 10% FBS. All cultures contained penicillin-streptomycin (100 U/ml).

Chemicals and reagents

Manassantin B (CSC27) was isolated from the roots of Saururus chinensis (33). LY294002,
HS173, TGX211, AS252424, CAL101, AT7867 and BEZ235 were purchased from Medchem Express. These compounds were dissolved in dimethyl sulfoxide (DMSO) and diluted to different concentrations before being added to P3HR-1, 293T cell cultures. The final DMSO concentration in the culture medium was maintained below 0.5%.

12-O-Tetradecanoyl-phorbol-13-acetate (TPA) and sodium butyrate (NaB) were purchased from Sigma-Aldrich. Goat anti-human IgG was purchased from Hua Yang Zheng Long. mTOR pathway antibody sampler kit, Phospho-Akt Pathway Antibody Sampler Kit, and antibodies against Phospho-p44/42 MAPK (ERK1/2) (Thr202/Tyr204), p44/42 MAPK (ERK1/2), Phospho-MEK1/2 (Ser217/221), Phospho-p70 S6 Kinase (Thr389), p70 S6 Kinase and Phospho-PKCδ (Ser643) were obtained from Cell Signal Technologies. Antibody against β-actin was purchased from Sigma-Aldrich. Antibodies against PKCα, phospho-PKCα (Ser657), phospho-PKCα (Ser638), EBV ZTA and EBV EA-D were obtained from Santa Cruz Biotechnology.

Quantification of intracellular EBV genomic DNA

P3HR-1 cells were induced with 20 ng/mL TPA and 0.3 mM NaB for EBV reactivation. Akata-BX1 cells were induced with 8 µg/ml IgG. Three hours post-induction, CSC27 or other compounds in dilutions were added to cells. Cells were harvested at 48 hours post-induction and total DNAs were purified using Qiagen RNeasy kit. EBV genomic DNA copy number was quantified by real time PCR on a Roche LightCycler 480 instrument using primers specified for EBNA1 (forward primer: 5’-CATTGAGTCGTCTCCCCCTTGGGAAT-3’ and reverse primer: 5’-TCATAAACAAGGTCTTAAATCGCATC-3’). The intracellular viral genomic DNA in each sample was normalized to GAPDH using primers directed to GAPDH (forward: 5’-ACATCATCCCCGCTCCTAC-3’, and reverse: 5’-TCAGGGTGGAAATGTGGG-3’). The half-maximal inhibitory concentration (IC50) values of compounds were determined from a dose-response curve of EBV DNA content values from TPA-induced and chemical-treated cells. The viral DNA contents with those of uninduced cells subtracted were divided by those of the control cells with no drug treatment and then represented on the y axes of dose-response curves: 

\[ y \text{ axis value} = \frac{(\text{TPA}_X-\text{noTPA})}{(\text{TPA}_0-\text{noTPA})}, \]

where X is any concentration of the drug and 0 represents nondonor treatment. The IC50 on viral DNA synthesis for each compound was calculated with the aid of GraphPad Prism software.

Quantification of extracellular EBV genomic DNA

Five days post-induction, P3HR-1 and Akata-BX1 culture media were collected and extracellular virions were pelleted from the medium supernatant. To remove contaminating DNA outside viral particles, the concentrated viruses were treated with Turbo DNase I (Ambion) at 37°C for 1 h, followed by proteinase K digestion. Virion DNA was extracted with phenol-chloroform, precipitated with ice-cold ethanol, and then dissolved in Tris-EDTA (TE) buffer. The EBV genomic copy numbers were determined by real-time PCR, and the values were corrected as described above. The half-maximal antiviral effective concentration (EC50) values were calculated from dose-response curves with GraphPad Prism software.

Cytotoxicity assay

P3HR-1, Akata-BX1 and PBMCs were treated with CSC27 in a wide range of concentration for 2 days. The viability of cells was assessed by counting Trypan blue-stained cells using a Countstar instrument. The half-maximal cytotoxic concentration (CC50) was calculated from dose-response curves with Graph-Pad Prism software.

Western blotting assay

Cells were lysed with lysis buffer (50 mM Tris-HCl, pH 7.4, 150 mM NaCl, 1% NP-40, 10% glycerol, 40 mM β-glycerophosphate, 30 mM sodium fluoride, 5 mM EDTA, protease inhibitor cocktail (Roche), 1 mM sodium orthovanadate). Lysates were subsequently denatured, resolved by SDS-PAGE and transferred to nitrocellulose
membranes. Membranes were reacted with the primary antibodies. Anti-Infrared Dye 800 or Dye 680 anti-rabbit or anti-mouse IgG were used as the secondary antibodies. The images were visualized using the LICOR Odyssey system. All immunoblottings were repeated at least twice, and representative images are shown.

**Electrophoretic mobility shift assay (EMSA)**

Two double stranded oligonucleotides were synthesized, one containing consensus AP-1 binding site (5'-CGCTTGATGACTCAGCCGGAA-3') and the other harboring the ZII region of the ZTA promoter (5'-ACGTCCCAAACCATGACATCACAGGAGGCT-3'). Oligonucleotides were end-labeled with 3'Cy5 before being annealed to form double-stranded DNA fragments. Nuclear protein extracts were prepared using Low-salt buffer (10 mM HEPES-KOH, pH7.5, 0.05%NP40, 10 mM KCl, 1.5 mM MgCl₂, 0.1 mM EDTA, 0.5 mM DTT, 1 mM PMSF, protease inhibitor cocktail, 1 mM NaF, 1mM NaNO₃) and High-salt extraction buffer (20 mM HEPES-KOH pH 7.5, 500 mM KCl, 1.5 mM MgCl₂, 0.2 mM EDTA, 10% glycerol, 0.5 mM DTT, 1 mM PMSF, protease inhibitor cocktail, 1 mM NaF, 1mM NaNO₃). EMSA were carried out in EMSA reaction buffer (10 mM Tris-HCl pH7.5, 50 mM KCl, 0.5 mM MgCl₂, 1mM DTT, 2.5% glycerol) for 30min in 15°C. The DNA-protein complexes were resolved on 5.5% native polyacrylamide gels at 4°C, 120V for 1 h and then scanned with an Odyssey imager (LI-COR). Unlabeled DNA fragments of ZII and AP-1 were used to determine binding specificity.

**Luciferase assay**

The promoter-reporter plasmid pAP-1-luc was provided by Dr. Ersheng Kuang at Sun Yat-sen University. 293T cells grown in 48-wells plates were co-transfected with 50 ng of pAP-1-luc and 5 ng of pRL-TK using lipofectamine 2000 reagent (Life Technologies). 6 hours after transfection, cells were treated with TPA. The pRL-TK plasmid expresses Renilla luciferase was used as an internal control. 36 hours post-induction, the luciferase assay was performed with Promega’s Dual-luciferase assay kit. Each sample was duplicated and each experiment was repeated at least three times.

**shRNA-mediated gene silencing**

The shRNA lentiviral vectors targeting mTOR (Clone ID: NM_004958.2-5477s1c1; NM_004858.2-7897s1c1), Raptor (Clone ID: NM_020761.1-4689s1c1; NM_020761.1-4325s1c1), Rictor (Clone ID:NM_152756.2-2620s1c1; NM_152756.3-5273s21c1) was purchased from Sigma-Aldrich. Lentiviral particles were prepared by transfection HEK293T cells with pLKO.1-shRNA plasmid (or pLKO.1-shControl plasmid), miR8.2 packing plasmid, and pCMV-VSV-G plasmid in the ratio of 4:3:1. Media containing lentiviruses were harvested at 48 h and 72 h and subjected to ultracentrifugation to concentrate the lentiviruses. Then the concentrated lentiviruses were used to transduce P3HR-1 cells, followed by selection under 2 μg/ml puromycin for a week. The knock down efficiencies were verified by Western analysis.

**Data Availability**

All data described are contained within the manuscript.

**Acknowledgment**

We thank members in Yuan Lab for discussion and constructive suggestions. We are grateful to Musheng Zeng at Sun Yat-sen University Cancer Center and Ersheng Kuang at Sun Yat-sen University for providing cell lines and reagents. This work is supported by grants from NIH (P01CA174439), National Natural Science Foundation of China (81530069, 81772177). QG is partially supported by the Science and Technology Program of Guangdong Province (20171048).

**Conflict of interest**

The authors declare that they have no conflicts of interest with the contents of this article.

Fig. 1. Effect of manassantin on EBV lytic replication. (A) Structure of manassantin B (CSC27). (B) P3HR-1 cells were treated with a wide range concentration of manassantin B three hours after being induced by TPA and sodium butyrate (NaB) for EBV lytic replication. Intracellular EBV DNA replication (blue), extracellular EBV virion production (green), and cell viability (orange) were determined as described in Experimental Procedures. The mean values from three independent experiments and standard deviations are presented on the y-axis of dose-response curves. Calculated IC$_{50}$, EC$_{50}$ and CC$_{50}$ are presented in the table. (C) Akata-BX1 cells were treated
with manassantin B in a wide range concentration three hours after being induced by anti-IgG antibody for EBV lytic replication. Intracellular EBV DNA replication (blue), extracellular EBV virion production (green), and cell viability (orange) were determined and presented as IC$_{50}$, EC$_{50}$ and CC$_{50}$ in the table below. (D) The cytotoxicity of manassantin B to peripheral blood mononuclear cells (PBMC) was assessed after 48 h treatment by trypan blue staining. (E) The effect of manassantin B on ZTA and RTA mRNA levels in TPA/NaB-induced P3HR-1 cells were determined using qRT-PCR at 24 h post-induction. (F) The expression of ZTA and EA-D were detected by Western blot analysis at 24 h post-induction.
Fig. 2. Manassantin B blocks AP-1 binding to AP-1-responsive promoter and the BZLF1 promoter. (A) A Cy5-labeled double-stranded oligonucleotide containing a consensus AP-1 binding motif and (B) a double-stranded oligonucleotide of ZII element of the BZLF1 promoter were incubated with the nuclear extracts (NE) prepared from TPA/NaB-induced P3HR-1 cells that were treated with manassantin B in various concentrations. Protein DNA complexes were resolved by electrophoretic mobility shift assay (EMSA). Unlabeled DNA duplexes were used to determine binding specificity. (C and D) The nuclear extracts (NE) prepared from TPA/NaB-induced P3HR-1 cells that were not treated with Manassantin B were incubated with the same double-stranded oligonucleotides above and manassantin B in different concentrations. Protein DNA complexes were resolved by electrophoretic mobility shift assay (EMSA). (E) 293T cells were co-transfected

16
with pAP-1-promotor-luciferase vector and pRL-TK control vector, followed by induction with TPA. Manassantin B in a wide range of concentration was added to the culture medium. The promoter activities were measured after 36 h post-treatment using a luciferase assay, normalized by Renilla luciferase activity.
**Fig. 3. mTOR is critical for EBV lytic replication.** (A) List of PI3K/AKT/mTOR inhibitors used in this experiment and their targets, IC₅₀ and 10×IC₅₀. (B) Each inhibitor listed in panel A was added to TPA/NaB-induced P3HR-1 cells at concentration of approximate 10xIC₅₀. EBV lytic DNA replication was determined by real-time PCR and (C) the associated cytotoxicity of each inhibitor to P3HR-1 cells was assessed by trypan blue staining. (D) The effect of each inhibitor on EBV ZTA expression was determined by Western blot 24 h after treatment. (E) A wide range concentration of Rapamycin (Rapa) was used to examine the effect of the mTORC1 inhibitor on EBV gene expression (ZTA and EA-D) as well as EBV lytic DNA replication. (F) A wide range
concentration of BEZ235 was used to analyze the effect of the dual inhibitor on EBV gene expression (ZTA and EA-D) as well as EBV lytic DNA replication.
Fig. 4. Manassantin B inhibits mTORC2–PKC signaling pathways. The expression and phosphorylation of AKT, PKC, MEK, ERK, p70S6K and c-Jun were examined by Western blotting analysis at 24 h post-induction in the absence and presence of manassantin B.
**Fig. 5. mTORC2 is critical for EBV lytic replication.** shRNA lentivirus targeting mTOR (A), Rictor (B), and Raptor (C), along with a non-targeting control shRNA lentivirus (shCtr), were transduced into P3HR-1 cells. The effects of the shRNA on each target gene and EBV ZTA gene expression were determined by Western blot. (D) The cells stably expressing mTOR, Raptor, Rictor and control shRNAs were induced by TPA and NaB for lytic viral replication. EBV lytic DNA replication was evaluated at 48 h post-induction by qRT-PCR as described. (E) EBV virion production was assayed 5 days after induction as described in Experimental Procedures.
Fig. 6. The signaling network of mTORC2 that leads to activation of PKC pathway and reactivation of latent EBV. The mTORC2–PKC–AP-1–ZTA as well as mTORC2–AKT–ATF/CREB–ZTA axes are critical for EBV reactivation and Manassantin B (CSC27) blocks EBV reactivation by inhibiting mTORC2 kinase activity.
The mTOR Inhibitor Manassantin B Reveals A Crucial Role of mTORC2 Signaling in Epstein-Barr Virus Reactivation
