SKEW SCHUBERT FUNCTIONS AND THE PIERI FORMULA FOR FLAG MANIFOLDS

NANTEL BERGERON AND FRANK SOTTILE

Abstract. We show the equivalence of the Pieri formula for flag manifolds and certain identities among the structure constants, giving new proofs of both the Pieri formula and of these identities. A key step is the association of a symmetric function to a finite poset with labeled Hasse diagram satisfying a symmetry condition. This gives a unified definition of skew Schur functions, Stanley symmetric function, and skew Schubert functions (defined here). We also use algebraic geometry to show the coefficient of a monomial in a Schubert polynomial counts certain chains in the Bruhat order, obtaining a new combinatorial construction of Schubert polynomials.

Introduction

A fundamental open problem in the theory of Schubert polynomials is to find an analog of the Littlewood-Richardson rule. By this, we mean a bijective description of the structure constants for the ring of polynomials with respect to its basis of Schubert polynomials. Such a rule would express the intersection form in the cohomology of a flag manifold in terms of its basis of Schubert classes. Other than the classical Littlewood-Richardson rule (when the Schubert polynomials are Schur symmetric polynomials) little is known.

Using geometry, Monk [26] established a formula for multiplication by linear Schubert polynomials (divisor Schubert classes). A Pieri-type formula for multiplication by an elementary or complete homogeneous symmetric polynomial (special Schubert class) was given in [21], but only recently proven [29] using geometry. There are now several proofs [4, 27, 33, 31], some of which [27, 33, 31] are purely combinatorial.

In the more general setting of multiplication by a Schur symmetric polynomial, formulas for some structure constants follow from a family of identities which were proven using geometry [4]. Also in (ibid.) are combinatorial results about intervals in the Bruhat order which are formally related to these identities. A combinatorial (but not a bijective) formula was given for these coefficients [4] using the Pieri formula, which gave a direct connection between some of these order-theoretic results and identities.

A first goal of this paper is to deduce another identity [4, Theorem G (ii)] from the Pieri formula, and also to deduce the Pieri formula from these identities. This furnishes...
a new proof of the Pieri formula, shows its equivalence to these (seemingly) more general identities, and, together with the combinatorial proofs of the Pieri formula, gives a purely combinatorial proof of these identities.

A key step is the definition of a symmetric function associated to any finite symmetric labeled poset, which is a poset whose Hasse diagram has edges labeled with integers with a symmetry condition satisfied by its maximal chains. This gives a unified construction of skew Schur functions (for intervals in Young’s lattice of partitions), Stanley symmetric functions \cite{Stanley} (for intervals in the weak order on the symmetric group), and for intervals in a $k$-Bruhat order, skew Schubert functions (defined in another fashion in §1).

In \cite{Lascoux-Schutzenberger}, Lascoux and Schützenberger show that if a Schubert polynomial is expressed as a univariate polynomial in the first variable, then the coefficients are (explicitly determined) multiplicity-free sums of Schubert polynomials in the remaining variables. This may be used to show that Schubert polynomials are sums of monomials with non-negative coefficients. We use a cohomological formula \cite[Theorem 4.5.4]{Fulton} to generalize their result, obtaining a similar formula for expressing a Schubert polynomial as a polynomial in any variable. This also extends Theorem C (ii) of \cite{Fulton}, which identified the constant term of this expression. From this, we obtain a construction of Schubert polynomials purely in terms of chains in the Bruhat order, and a geometric proof that the monomials which appear in a Schubert polynomial have non-negative coefficients. The Pieri formula shows these coefficients are certain intersection numbers, recovering a result of Kirillov and Maeno \cite{Kirillov-Maeno}.

We found these precise formulas in terms of intersection numbers surprising; Other combinatorial constructions are either recursive \cite[4.17]{Remmel-Shimozono} and do not give the coefficients, or are expressed in terms of combinatorial structures (the weak order on the symmetric group \cite{Lam, Lam-Remmel, Remmel} or diagrams of permutations \cite{Remmel-Plant, Remmel-Shimozono}) which are not geometric. Previously, we believed this non-negativity of monomials had no relation to geometry. Indeed, only monomials of the form $x^\lambda$ with $\lambda$ a partition are represented by positive cycles, other polynomial representatives of Schubert classes \cite{Lam, Lam-Remmel} do not have this non-negativity, and polynomial representatives for the other classical groups cannot \cite{Lam} have such non-negativity.

This paper is organized as follows. In Section 1, we give necessary background, define skew Schubert functions, and state our main results. In Section 2, we deduce the Pieri formula from the identities and results on the Bruhat order. In Section 3, we define a symmetric function $S_P$ associated to a symmetric labeled poset $P$ and complete the proof of the equivalence of the Pieri formula and these identities. We also show how this construction gives skew Schur and Schubert functions. In Section 4, we adapt an argument of Remmel and Shimozono \cite{Remmel-Shimozono} to show that, for intervals in the weak order, this symmetric function is Stanley’s symmetric function \cite{Stanley}. Finally, in Section 5, we use a geometric result of \cite{Fulton} to generalize the result in \cite{Lascoux-Schutzenberger} and interpret the coefficient of a monomial in a Schubert polynomial in terms of chains in the Bruhat order.

1. Preliminaries

Let $S_n$ be the symmetric group on $n$ letters and $S_\infty := \bigcup_n S_n$, the group of permutations of $\mathbb{N}$ which fix all but finitely many integers. We let $1$ be the identity permutation. For each
w ∈ S_∞, Lascoux and Schützenberger [21] defined a Schubert polynomial \( S_w \in \mathbb{Z}[x_1, x_2, \ldots] \) with \( \deg S_w = \ell(w) \). These satisfy the following:

1. \( \{ S_w \mid w \in S_\infty \} \) is a \( \mathbb{Z} \)-basis for \( \mathbb{Z}[x_1, x_2, \ldots] \).
2. If \( w \) has a unique descent at \( k \) (\( w(j) > w(j+1) \Rightarrow j = k \)), then \( S_w = S_\lambda(x_1, \ldots, x_k) \), where \( \lambda_j = w(k+1-j) - k - 1 + j \). We write \( v(\lambda, k) \) for this permutation and call \( w \) a Grassmannian permutation with descent \( k \).

By the first property, there exist integral structure constants \( c_{uv}^w \) for \( w, u, v \in S_\infty \) (non-negative from geometry) defined by the identity

\[
S_u \cdot S_v = \sum_w c_{uv}^w S_w.
\]

We are concerned with the coefficients \( c_{uv}^w(\lambda, k) \) which arise when \( S_v \) in (1) is replaced by the Schur polynomial \( S_\lambda(x_1, \ldots, x_k) = S_{w(\lambda, k)} \).

It is well-known (see for example [29, 3]) that \( c_{uv}^w(\lambda, k) \neq 0 \) only if \( u \leq_k w \), where \( \leq_k \) is the \( k \)-Bruhat order (introduced in [23]). In fact, \( u \leq_k w \) if and only if there is some \( \lambda \) with \( c_{uv}^w(\lambda, k) \neq 0 \). This suborder of the Bruhat order has the following characterization:

**Definition 1.1** (Theorem A of [3]). Let \( u, w \in S_\infty \). Then \( u \leq_k w \) if and only if

1. \( a \leq k < b \Rightarrow u(a) \leq w(a) \) and \( u(b) \geq w(b) \),
2. \( a < b, u(a) < u(b), \) and \( w(a) > w(b) \) \( \Rightarrow a \leq k < b \).

For any infinite subset \( P \) of \( \mathbb{N} \), the order-preserving bijection \( \mathbb{N} \leftrightarrow P \) and the inclusion \( P \to \mathbb{N} \) induce a map

\[
\varepsilon_P : S_\infty \simeq S_P \leftrightarrow S_\infty.
\]

**Shape-equivalence** is the equivalence relation generated by \( \zeta \sim \varepsilon_P(\zeta) \) for \( P \subset \mathbb{N} \).

If \( u \leq_k w \), let \( [u, w]_k \) denote the interval between \( u \) and \( w \) in the \( k \)-Bruhat order. These intervals have the following property:

**Order 1** (Theorem E(i) of [3]). Suppose \( u, w, y, z \in S_\infty \) with \( u \leq_k w, y \leq, z, \) and \( wu^{-1} \) shape-equivalent to \( zy^{-1} \). Then \( [u, w]_k \simeq [y, z]_l \). Moreover, if \( zy^{-1} = \varepsilon_P(wu^{-1}) \), then this isomorphism is induced by the map \( v \mapsto \varepsilon_P(vu^{-1})y \).

This has a companion identity among the structure constants \( c_{uv}^w(\lambda, k) \):

**Identity 1** (Theorem E(ii) of [3]). Suppose \( u, w, y, z \in S_\infty \) with \( u \leq_k w, y \leq, l, \) and \( wu^{-1} \) shape-equivalent to \( zy^{-1} \). Then, for any partition \( \lambda \),

\[
c_{uv}^w(\lambda, k) = c_{yl}^z(\lambda, l).
\]

This identity was originally proven using geometry [3]. In [4], we showed how to deduce it from Order 1 and the Pieri formula for Schubert polynomials. Here, we use it to deduce the Pieri formula.

By Identity 1, we may define a constant \( c_{\zeta}^w(\lambda) \) for any permutation \( \zeta \in S_\infty \) and any partition \( \lambda \) by \( c_{\zeta}^w(\lambda) = c_{uv}^w(\lambda, k) \) for any \( u \leq_k w \) with \( w = \zeta u \). We also define the *skew Schubert function*
where $S_\lambda$ is the Schur symmetric function \cite{25}.

By Order 1, we may make the following definition:

**Definition 1.2.** Let $\eta, \zeta \in S_\infty$. Then $\eta \preceq \zeta$ if and only if there is a $u \in S_\infty$ and $k \in \mathbb{N}$ with $u \leq_k \eta u \leq_k \zeta u$. For $\zeta \in S_\infty$, define $|\zeta| := \ell(\zeta u) - \ell(u)$ for any $u, k$ with $u \leq_k \zeta u$. (There always is such a $u$ and $k$, see \S 2.)

In \S 2, $\preceq$ and $|\zeta|$ are given definitions that do not refer to $\leq_k$ or $\ell(w)$.

Let $\zeta, \eta \in S_\infty$. If we have $\eta \cdot \zeta = \zeta \cdot \eta$ with $|\zeta \cdot \eta| = |\zeta| + |\eta|$, and neither of $\zeta$ or $\eta$ is the identity, then we say that $\zeta \cdot \eta$ is the disjoint product of $\zeta$ and $\eta$. If a permutation cannot be written in this way, then it is irreducible. It is a consequence of \cite{3, \S 3} that a permutation $\zeta$ factors uniquely into irreducibles as follows: Let $P$ be the finest non-crossing partition \cite{19} which is refined by the partition given by the cycles of $\zeta$. For each non-singleton part $p$ of $P$, let $\zeta_p$ be the product of cycles which partition $p$. Each $\zeta_p$ is irreducible, and $\zeta$ is the disjoint product of the $\zeta_p$’s. See Remark 3.7 for a further discussion.

**Order 2** (Theorem G(i) of \cite{3}). Suppose $\zeta = \zeta_1 \cdots \zeta_t$ is the factorization of $\zeta \in S_\infty$ into irreducibles. Then the map $(\eta_1, \ldots, \eta_t) \mapsto \eta_1 \cdots \eta_t$ induces an isomorphism

$$[1, \zeta_1] \times \cdots \times [1, \zeta_t] \longrightarrow [1, \zeta].$$

**Identity 2** (Theorem G(ii) of \cite{3}). Suppose $\zeta = \zeta_1 \cdots \zeta_t$ is the factorization of $\zeta \in S_\infty$ into irreducibles. Then

$$S_\zeta = S_{\zeta_1} \cdots S_{\zeta_t}.$$}

Theorem G(ii) in \cite{3} states that if $\zeta \cdot \eta$ is a disjoint product, then, for all partitions $\lambda$,

$$c^\zeta_\eta = \sum_{\mu, \nu} c^\lambda_{\mu, \nu} c^\eta_{\mu, \nu}.$$ 

Thus we see that

$$S_\zeta \cdot S_\eta = \sum_{\mu, \nu} c^\zeta_\eta S_\mu S_\nu$$

$$= \sum_{\lambda, \mu, \nu} c^\lambda_{\mu, \nu} c^\eta_{\mu, \nu} S_\lambda$$

$$= \sum_{\lambda} c^\zeta_\eta S_\lambda = S_\zeta_\eta.$$ 

Iterating this shows the equivalence of Theorem G(ii) of \cite{3} and Identity 2.

A *labeled poset* $P$ is a finite ranked poset together with an integer label for each cover. Its Hasse diagram is thus a directed labeled graph with integer labels. Write $u \rightarrow^b w$ for
a labeled edge in this Hasse diagram. In what follows, we consider four classes of labeled posets:

**Intervals in a k-Bruhat order.** Labeling a cover \( u \preceq_k w \) in the k-Bruhat order with \( b \), where \( wu^{-1} = (a, b) \) and \( a < b \) gives every interval in the k-Bruhat order the structure of a labeled poset.

**Intervals in the \( \leq \)-order.** Likewise, a cover \( \eta \prec \zeta \) in the \( \leq \)-order gives a transposition \((a, b) = \zeta \eta^{-1} \) with \( a < b \). Labeling such a cover with \( b \) gives every interval in this order the structure of a labeled poset. Since \([\eta, \zeta] \preceq [1, \zeta \eta^{-1}] \preceq \), it suffices to consider intervals of the form \([1, \zeta] \preceq \).

**Intervals in Young’s lattice.** A cover \( \mu \subseteq \lambda \) in Young’s lattice of partitions gives a unique index \( i \) with \( \mu_i + 1 = \lambda_i \). Labeling such a cover with \( \lambda_i - i \) gives every interval in Young’s lattice the structure of a labeled poset.

**Intervals in the weak order.** Finally, labeling a cover \( u \preceq_{\text{weak}} w \) in the weak order on \( S_{\infty} \) with the index \( i \) of the transposition \( wu^{-1} = (i, i+1) \) gives every interval in the weak order the structure of a labeled poset. Since, for \( u \preceq_{\text{weak}} w \), \([u, w]_{\text{weak}} \simeq [1, wu^{-1}]_{\text{weak}} \), it suffices to consider intervals of the form \([1, w]_{\text{weak}} \).

The sequence of edge labels in a (maximal) chain of a labeled poset is the *word* of that chain. For a composition \( \alpha = (\alpha_1, \ldots, \alpha_k) \) of \( m = \text{rank} P \), let \( H_{\alpha}(P) \) be the set of maximal chains in \( P \) whose word has descent set contained in \( I(\alpha) := \{\alpha_1, \alpha_1 + \alpha_2, \ldots, m - \alpha_k\} \). We say that \( P \) is *symmetric* if the cardinality of \( H_{\alpha}(P) \) depends only upon the parts of \( \alpha \) and not their order.

Each poset in the above classes is symmetric: For the k-Bruhat orders or \( \preceq \)-order, this is a consequence of the Pieri formula for Schubert polynomials. For Young’s lattice, this is classical, and for intervals in the weak order, it is due to Stanley [30].

We wish to consider skew Young diagrams to be equivalent if they differ by a translation. This leads to the following notion of isomorphism for labeled posets.

**Definition 1.3.** A map \( f : P \to Q \) between labeled posets is an isomorphism if \( f \) is an isomorphism of posets which preserves the relative order of the edge labels.

That is, if \( e, e' \) are edges of \( P \) with respective labels \( a \leq a' \), then the edge labels \( b, b' \) of \( f(e), f(e') \) in \( Q \) satisfy \( b \leq b' \). The isomorphisms of Order 1 and Order 2 are isomorphisms of labeled posets. We also see that the interval \([\mu, \lambda] \subseteq \) in Young’s poset is isomorphic to the interval \([v(\mu, k), v(\lambda, k)] \subseteq \) in the k-Bruhat order and the corresponding cover \( \alpha \subseteq \beta \) in Young’s lattice is \( k + 1 \).

To every symmetric labeled poset \( P \), we associate (Definition 3.6) a symmetric function \( S_P \) which has the following properties:

**Theorem 1.4.**

1. If \( P \simeq Q \), then \( S_P = S_Q \).
2. If \( u \preceq_k w \), then \( S_{[u, w]} = S_{wu^{-1}} \), the skew Schubert function.
3. For \( \zeta \in S_{\infty} \), \( S_{[1, \zeta]} = S_\zeta \), the skew Schubert function.
4. Let \( \mu \subseteq \lambda \) be partitions. Then \( S_{[\mu, \lambda]} = S_{\lambda/\mu} \), the skew Schur function.
5. For \( w \in S_{\infty} \), we have \( S_{[1, w]} = F_w \), the Stanley symmetric function.
Part 1 is Lemma 3.2(2), parts 2, 2′, and 3 are proven in §3, and part 4 in §4.

A labeled poset $P$ is an increasing chain if it is totally ordered with increasing edge labels. A cycle $\zeta \in S_\infty$ is increasing if $[1, \zeta]_\leq$ is an increasing chain. Decreasing chains and cycles are defined similarly.

For any positive integers $m, k$ let $r[m, k]$ denote the permutation $v((m, 0, \ldots, 0), k)$ which is the increasing cycle $(k+m, k+m-1, \ldots, k)$. It is an easy consequence (see Lemma 2.1) of the definitions of $\leq_k$ or $\leq$ that any increasing cycle $\zeta$ of length $m+1$ is shape equivalent to $r[m, k]$ and hence $|\zeta| = m$. Likewise, the permutation $v(1^m, k)$ is the decreasing cycle $(k+1-m, \ldots, k, k+1)$ and any decreasing cycle of length $m+1$ is shape equivalent to $v(1^m, k)$ for any $k \geq m$. Here $1^m$ is the partition of $m$ into $m$ equal parts of size 1. Note that

$$S_{r[m, k]} = h_m(x_1, \ldots, x_k) \quad \text{and} \quad S_{v(1^m, k)} = e_m(x_1, \ldots, x_k),$$

the complete homogeneous and elementary symmetric polynomials.

**Proposition 1.5** (Pieri formula for Schubert polynomials and flag manifolds). Let $u \leq_k w$ with $m = \ell(w) - \ell(u)$. Then

1. $c_{u w}^{r[m, k]} = \begin{cases} 1 & \text{if } w u^{-1} \text{ is the disjoint product of increasing cycles} \\ 0 & \text{otherwise.} \end{cases}$

2. $c_{v(1^m, k)}^{u v} = \begin{cases} 1 & \text{if } w u^{-1} \text{ is the disjoint product of decreasing cycles} \\ 0 & \text{otherwise.} \end{cases}$

This is the form of the Pieri formula stated in [21], as such a disjoint products of increasing (decreasing) cycles are $k$-soulèvements droits (respectively gauches) for $u$. By [24, Lemma 6], $w u^{-1}$ is a disjoint product of increasing cycles if and only if there is a maximal chain in $[u, w]_k$ with increasing labels, and such chains are unique. When this occurs, we write $u \overset{r[m, k]}{\rightarrow} w$, where $m := \ell(w) - \ell(u)$. Similarly, $w u^{-1}$ is a disjoint product of decreasing cycles if and only if there is a maximal chain in $[u, w]_k$ with decreasing labels, which is necessarily unique.

Recall that

$$H^*(\text{Flags}(\mathbb{C}^n)) \simeq \mathbb{Z}[x_1, x_2, \ldots]/(S_w \mid w \not\in S_n) = \mathbb{Z}[x_1, \ldots, x_n]/(x_\alpha \mid \alpha_i \geq n - i, \text{ for some } i).$$

The map defined by $S_w \mapsto \overline{S_w}$, where $\overline{w} = \omega_0 w \omega_0$, conjugation by the longest element $\omega_0$ in $S_n$, is an algebra involution on $H^*(\text{Flags}(\mathbb{C}^n))$. If $n \geq k + m$, then this involution shows the equivalence of the two versions of the Pieri formula.

We state the main results of this paper:

**Theorem 1.6.** Given the results Order 1 and 2 on the $k$-Bruhat orders/\leq-order, the Pieri formula for Schubert polynomials is equivalent to the Identities 1 and 2.

This is proven in §2 and §3.

**Theorem 1.7.** If $w \in S_n$ and $0 \leq \alpha_i \leq n - i$ for $1 \leq i \leq n - 1$, then the coefficient of $x_1^{n-1-\alpha_1} x_2^{n-2-\alpha_2} \cdots x_{n-1}^{1-\alpha_{n-1}}$ in the Schubert polynomial $S_w(x)$ is the number of chains

$$w \overset{r[\alpha_1, 1]}{\rightarrow} w_1 \overset{r[\alpha_2, 2]}{\rightarrow} \cdots \overset{r[\alpha_{n-1}, n-1]}{\rightarrow} \omega_0$$
between \( w \) and \( \omega_0 \), the longest element in \( S_n \).

This is a restatement of Corollary 5.3.

2. Proof of the Pieri formula for Schubert polynomials and flag manifolds

Here, we use Identities 1 and 2 to deduce the Pieri formula. We first establish some combinatorial facts about chains and increasing/decreasing cycles.

Let \( \zeta \in S_\infty \). We give a \( u \in S_\infty \) and \( k > 0 \) such that \( u \leq_k \zeta u \) and \( \zeta u \) is Grassmannian of descent \( k \). Define \( \text{up}(\zeta) := \{a \mid a < \zeta(a)\} \), \( \text{down}(\zeta) := \{b \mid b > \zeta(b)\} \), \( \text{fix}(\zeta) := \{c \mid c = \zeta(c)\} \), and set \( k := \#\text{up}(\zeta) \). If we have

\[
\text{up}(\zeta) = \{a_1, \ldots, a_k \mid \zeta(a_1) < \zeta(a_2) < \cdots < \zeta(a_k)\},
\]

\[
\text{fix}(\zeta) \bigcup \text{down}(\zeta) = \{b_1, b_2, \ldots \mid \zeta(b_1) < \zeta(b_2) < \cdots\},
\]

and define \( u \in S_\infty \) by

\[
u := \begin{cases} a_i & \text{if } i \leq k \\ b_{i-k} & \text{if } i > k \end{cases},
\]

then \( u \leq_k \zeta u \). Set \( w := \zeta u \).

This construction of \( u \in S_\infty \) is Theorem 3.1.5 (ii) of [3]. There, we also show that \( \eta \preceq \zeta \) if and only if

1. \( a \in \text{up}(\zeta) \implies \eta(a) \leq \zeta(a) \).
2. \( b \in \text{down}(\zeta) \implies \eta(b) \geq \zeta(b) \).
3. \( a, b \in \text{up}(\zeta) \) (or \( a, b \in \text{down}(\zeta) \)) with \( a < b \) and \( \zeta(a) < \zeta(b) \implies \eta(a) < \eta(b) \).

Lemma 2.1. Let \( \zeta \in S_\infty \). The labeled poset \([1, \zeta]_{\preceq}\) is a chain if and only if \( \zeta \) is either an increasing or a decreasing cycle. Moreover, if \( \zeta \) is an increasing (decreasing) cycle of length \( m+1 \), then the chain \([1, \zeta]_{\preceq}\) is increasing (decreasing) and \( \zeta \) is shape-equivalent to \( r[m, 1] \) \((v(1^m, m))\).

Proof. Let \( \zeta \in S_\infty \) and construct \( u \leq_k \zeta u \) as above. Set \( m := \ell(\zeta u) - \ell(u) \), and consider any chain in \([u, w]_k\):

\[
u = u_0 \xrightarrow{b_1} u_1 \xrightarrow{b_2} u_2 \cdots u_{m-1} \xrightarrow{b_m} u_m = w.
\]

Suppose that the poset \([1, \zeta]_{\preceq}\) \(\simeq [u, \zeta u]_k\) is a chain. By Order 2, \( \zeta \) is irreducible. We show that \( \zeta \) is either an increasing or a decreasing cycle by induction on \( m \). Suppose \( \eta = u_{m-1}^{-1}u^1 \) is an increasing cycle. Then \( \eta = (b_{m-1}, b_{m-2}, \ldots, b_1, a_1) \) where \( u_1 = (a_1, b_1)u \) and \( u_i = (b_{i-1}, b_i)u_{i-1} \) for \( i > 1 \). Let \( \zeta = (a_m, b_m)\eta \).

Since \( u_{m-1}^{-1}(b_{m-1}) \leq k \) and \( u_{m-1}^{-1}(b_m) > k \), we must have \( b_{m-1} \neq b_m \). If \( b_m > b_{m-1} \) so that \([1, \zeta]_{\preceq}\) is increasing, then, as \( \zeta \) is irreducible, we must have \( a_m = b_{m-1} \) and so \( \zeta \) is the increasing cycle

\((b_m, b_{m-1}, \ldots, b_1, a_1)\).
Indeed, if either \(a_m > b_{m-1}\) or \(a_m < b_{m-2}\), then \([1, \zeta]_x\) is not a chain, and \(b_{m-1} > a_m \geq b_{m-2}\) contradicts \(u_{m-2} = k u_{m-1} < k u_m\). Suppose now that \(b_m < b_{m-1}\), then the irreducibility of \(\zeta\) implies that \(m = 2\) and \(b_m = a_1\), so that \([1, \zeta]_x\) is decreasing and \(\zeta\) is a decreasing cycle.

Similar arguments suffice when \(\eta = u_{m-1} u^{-1}\) is a decreasing cycle, and the other statements are straightforward. \(\square\)

**Proof that Identities 1 and 2 imply the Pieri formula.**

Let \(\zeta \in \mathcal{S}_\infty\) and suppose \(c_{(m,0,...,0)}^\zeta \neq 0\). Then \(m = |\zeta|\), by homogeneity. Replacing \(\zeta\) by a shape-equivalent permutation if necessary, we may assume that \(\zeta \in \mathcal{S}_n\) and \(\zeta(i) \neq i\) for each \(1 \leq i \leq n\).

Define \(u\) and \(w := \zeta u\) as in the first paragraph of this section, so that \(u, w \in \mathcal{S}_n\) and \(c_{(m,0,...,0)}^u = c_{w[m,k]}^w\). Since \(c_{w[m,k]}^w \neq 0\), we must have \(m = n - k = \#\text{down}(\zeta)\): Consider any chain

\[
(3) \quad u = u_0 \xrightarrow{b_1} u_1 \xrightarrow{b_2} u_2 \cdots u_{m-1} \xrightarrow{b_m} u_m = w
\]

in \([u, w]_k\). Then \(\text{down}(\zeta) \subseteq \{b_1, \ldots, b_m\}\) so that \(m \geq n - k\). However, \(c_{w[m,k]}^w \neq 0\) and \(w \in \mathcal{S}_n\) implies that \(r[m,k] \in \mathcal{S}_n\), and hence \(k + m \leq n\). It follows that \(\text{down}(\zeta) = \{b_1, \ldots, b_m\}\). Thus if we have \(u_i = u_{i-1}(c_i, d_i)\) with \(c_i \leq k < d_i\), then by the construction of \(u\), \(\{d_1, \ldots, d_m\} = \{k+1, \ldots, k+m = n\}\).

Consider the case when \(\zeta\) is irreducible. Then we must have \(c_1 = c_2 = \cdots = c_m\). This implies that \(k = \#\text{up}(\zeta) = 1\), and \(m = n - 1\). By (1) of Definition \(\[\]\) we must then have \(b_1 < b_2 < \cdots < b_m\), and hence \(\zeta = (n, n-1, \ldots, 2, 1)\), an increasing cycle. But this is \(r[n-1,1]\), so \(u = 1\), the identity permutation. Since \(c_{1 \nu}^w = \delta_{w,v}\), the Kronecker delta, \(c_{\lambda}^\zeta = \delta_{\lambda,(m,0,...,0)}\) and so \(S_{\zeta} = h_{n-1}\).

If more generally we have \(\eta \in \mathcal{S}_\infty\) with \(\#\text{down}(\eta) = |\eta| = m\) and \(\eta\) irreducible, then considering a shape-equivalent \(\zeta \in \mathcal{S}_n\) with \(n\) minimal, we see that \(\eta\) is an increasing cycle and \(S_{\eta} = h_m\).

We return to the case of \(\zeta \in \mathcal{S}_n\) with \(c_{(m,0,...,0)}^\zeta \neq 0\). Let \(\zeta = \zeta_1 \cdots \zeta_t\) be the disjoint factorization of \(\zeta\) into irreducibles. Then each \(\zeta_i\) is an increasing cycle. Suppose that \(m_i = |\zeta_i|\). By Identity 2, we have that

\[
S_\zeta = S_{\zeta_1} \cdots S_{\zeta_t} = h_{m_1} \cdots h_{m_t}.
\]

This is equivalent to \([23],\) Theorem 5\). From this, we deduce that \(c_{\lambda}^\zeta = c_{\mu \lambda}^\nu\), where \(\mu / \nu\) is a horizontal strip with \(m_i\) boxes in the \(i\)th row. By the classical Pieri formula for Schur polynomials, this implies that \(c_{(m,0,...,0)}^\zeta = 1\). \(\square\)

3. **Skew Schur functions from labeled posets**

In \([4],\) Theorem 4.3\), we showed how the Pieri formula implies Identity 1. Here we complete the proof of Theorem \([\[\]\) showing how the Pieri formula implies Identity 2. The first step is a reinterpretation of a construction in \([4],\) §4\) from which we associate a symmetric
function to any symmetric labeled poset. For intervals in Young’s lattice, we obtain skew Schur functions, and for intervals in either a $k$-Bruhat order or the $\preceq$-order, skew Schubert functions. In Section 4, we show that for intervals in the weak order we obtain Stanley symmetric functions.

Let $P$ be a labeled poset with total rank $m$. A (maximal) chain in $P$ gives a sequence of edge labels, called the word of that chain. A composition $\alpha := (\alpha_1, \ldots, \alpha_k)$ of $m = \alpha_1 + \cdots + \alpha_k$ ($\alpha_i \geq 0$), determines, and is determined by a (multi)subset $I(\alpha) := \{\alpha_1, \alpha_1 + \alpha_2, \ldots, \alpha_1 + \cdots + \alpha_k\}$ of $\{1, \ldots, m\}$. For a composition $\alpha$ of $m = \text{rank} P$, let $H_\alpha(P)$ be the set of (maximal) chains in $P$ whose word $w$ has descent set $\{j \mid w_j > w_{j+1}\}$ contained in the set $I(\alpha)$. We adopt the convention that the last position of a word is a descent. If some $\alpha_i < 0$, then we set $H_\alpha(P) = \emptyset$. We say that $P$ is (label-) symmetric if the cardinality of $H_\alpha(P)$ depends only upon the parts of $\alpha$ and not their order.

Let $\Lambda$ be the $\mathbb{Z}$-algebra of symmetric functions. Recall that $\Lambda = \mathbb{Z}[h_1, h_2, \ldots]$, where $h_i$ is the complete homogeneous symmetric function of degree $i$, the sum of all monomials of degree $i$. For a composition $\alpha$, set

$$h_\alpha := h_{\alpha_1} h_{\alpha_2} \cdots h_{\alpha_k}.$$

**Definition 3.1.** Suppose $P$ is a symmetric labeled poset. Define the $\mathbb{Z}$-linear map $\chi_P : \Lambda \to \mathbb{Z}$ by

$$\chi_P : h_\alpha \mapsto \#(H_\alpha(P)).$$

For any partition $\lambda$, define the skew coefficient $c^P_\lambda$ to be $\chi_P(S_\lambda)$, where $S_\lambda$ is the Schur symmetric function.

We point out some properties of these coefficients $c^P_\lambda$. For a partition $\lambda$ of $m$ ($\lambda \vdash m$) with $\lambda_{k+1} = 0$ and a permutation $\pi \in S_k$, let $\lambda_\pi$ be the following composition of $m$:

$$\pi(1) - 1 + \lambda_{k+1-\pi(1)}, \pi(2) - 2 + \lambda_{k+1-\pi(2)}, \ldots, \pi(k) - k + \lambda_{k+1-\pi(k)}.$$

**Lemma 3.2.** Let $P, Q$ be symmetric labeled posets.

1. For any partition $\lambda$,

$$c^P_\lambda := \sum_{\pi \in S_k} \varepsilon(\pi) \#(H_{\lambda_\pi}(P))$$

where $\lambda_{k+1} = 0$ and $\varepsilon : S_k \to \{\pm 1\}$ is the sign character.

2. If $P \cong Q$ as labeled posets (Definition 1.3) then for any partition $\lambda$, $c^P_\lambda = c^Q_\lambda$.

The first statement follows from the Jacobi-Trudi formula, and the second by noting that the bijection $P \leftrightarrow Q$ induces bijections $H_\alpha(P) \leftrightarrow H_\alpha(Q)$.

**Remark 3.3.** By the Pieri formula for Schubert polynomials, the number $\#(H_\alpha([u, w]_k))$ is the coefficient of $\mathfrak{S}_w$ in the product $\mathfrak{S}_u \cdot h_\alpha(x_1, \ldots, x_k)$. It follows that intervals in a $k$-Bruhat order or in the $\preceq$-order are symmetric. For similar reasons, we see that intervals in Young’s lattice are symmetric, as $\#(H_\alpha([\mu, \lambda]_\preceq))$ is the skew Kostka coefficient $K_{\alpha, \lambda/\mu}$, which is the coefficient of $S_\lambda$ in $S_\mu \cdot h_\alpha$, equivalently, the number of semistandard Young tableaux of shape $\lambda/\mu$ and content $\alpha$. One may construct an explicit bijection with the
second set as follows: A chain in $H_\alpha([\mu, \lambda]_\subset)$ is naturally decomposed into subchains with increasing labels of lengths $\alpha_1, \alpha_2, \ldots, \alpha_k$. Placing the integer $i$ in the boxes corresponding to covers in the $i$th such subchain furnishes the bijection.

**Proposition 3.4** (Theorem 4.3 of [4]). Let $u \leq_k w$ and $\lambda \vdash \ell(w) - \ell(u) = m$. Then $c_{u,v}^{w(\lambda,k)} = c_{w}^{[u,w]_k}$.

**Proof.** By definition, $c_{u,v}^{w(\lambda,k)}$ is the coefficient of $\mathcal{G}_w$ in the expansion of the product $\mathcal{G}_u \cdot S_\lambda(x_1, \ldots, x_k)$ into Schubert polynomials. By the Jacobi-Trudi formula,

$$
\mathcal{G}_u \cdot S_\lambda(x_1, \ldots, x_k) = \sum_{\pi \in S_k} \varepsilon(\pi) h_{\lambda_\pi}(x_1, \ldots, x_k)
$$

$$
= \sum_{w} \sum_{\pi \in S_k} \varepsilon(\pi) \#(H_{\lambda_\pi}([u,w]_k)) \mathcal{G}_w
$$

$$
= \sum_{w} [w]^{[u,w]_k} \mathcal{G}_w. \quad \Box
$$

**Proposition 3.5** (Corollary 4.9 of [4]). If $u \leq_k w$ and $y \leq l$ $z$ with $wu^{-1}$ shape equivalent to $zy^{-1}$, then for all $\lambda$, $c_{u,v}^{w(\lambda,k)} = c_{y,v}^{z(\lambda,l)}$.

**Proof.** By Order 1, $[u,w]_k \cong [y,z]_l$ is an isomorphism of labeled posets. \(\Box\)

**Definition 3.6.** Let $P$ be a ranked labeled poset with total rank $m$. Define the symmetric function $S_P$ by

$$
S_P := \sum_{\lambda \vdash m} c_{\lambda}^{P} S_\lambda,
$$

where $S_\lambda$ is a Schur function.

**Proof of Theorem 1.4 (1), (2), and (3).** (1) is a consequence of Lemma 3.3 (2). For (3), let $\mu \subset \nu$ in Young’s lattice, suppose $\nu_{k+1} = 0$, and consider the interval $[\mu, \nu]_\subset$ in Young’s lattice. Then $[\mu, \nu] \cong [v(\nu, k), v(\nu, k)]_k$, and so $c_{\lambda}^{v(\nu,k)} = c_{v(\nu,k)}^{v(\nu,k)} = c_{\mu,\lambda}^{\nu}$. Hence $S_{[\mu,\nu]_\subset} = S_{v/\mu}$. Similarly, we see that for $u \leq_k w$ or $\zeta \in S_\infty$, we have $S_{[u,w]_k} = S_{wu^{-1}}$ and $S_{[1,\zeta]_\leq} = S_{\zeta}$, the skew Schubert functions of §4. \(\Box\)

**Remark 3.7.** According to Proposition 3.7, the skew Schubert function $S_\zeta$ depends only on the shape equivalence class of $\zeta$. In [3] there is another identity:

Theorem H of [3]. Suppose $\eta, \zeta \in S_n$ with $\zeta = \eta^{(12\ldots m)}$. Then $S_\eta = S_\zeta$.

The example of $\eta = (1243)$ and $\zeta = (1243)$ in $S_4$ (see Figure 1) shows that in general $[1,\eta]_\leq \not\cong [1,\eta^{(12\ldots m)}]_\leq$. However, these two intervals do have the same number of maximal chains [3] Corollary 1.4. In fact, for $\eta \in S_n$ and $\alpha$ a composition, $\#(H_\alpha([1,\eta]_\leq)) = \#(H_\alpha([1,\eta^{(12\ldots m)}]_\leq))$.

Thus if $\sim$ is the equivalence relation generated by shape equivalence and this ‘cyclic shift’ ($\eta \sim \eta^{(12\ldots m)}$, if $\eta \in S_n$), then $S_\zeta$ depends only upon the $\sim$-equivalence class of $\zeta$. (This is
analogous to, but stronger than the fact that the skew Schur function $S_\kappa$ depends on $\kappa$ only up to a translation in the plane.)

There is a combinatorial object $\Gamma_\zeta$ which determines the $\sim$-equivalence class of $\zeta$. First place the set \{a \mid a \neq \zeta(a)\} at the vertices of a regular \#\{a \mid a \neq \zeta(a)\}-gon in clockwise order. Next, for each $a$ with $a \neq \zeta(a)$, draw a directed chord from $a$ to $\zeta(a)$. $\Gamma_\zeta$ is the resulting configuration of directed chords, up to rotation and dilation and without any vertices labeled (cf. \cite[§3.3]{a}). The irreducible factors of $\zeta$ correspond to connected components of $\Gamma_\zeta$ (considered as a subset of the plane). The figure $\Gamma_{(1243)} = \Gamma_{(1423)}$ is also displayed in Figure 1.

\begin{figure}[h]
\centering
\includegraphics[width=0.8\textwidth]{figure1.png}
\caption{Intervals under cyclic shift and $\Gamma_\zeta$}
\end{figure}

Figure 1. Intervals under cyclic shift and $\Gamma_\zeta$

We conclude this section with the following Theorem:

**Theorem 3.8.** Let $P$ and $Q$ be symmetric labeled posets with disjoint sets of edge labels. Then

\[ S_{P \times Q} = S_P \cdot S_Q. \]

This will complete the proof of Theorem 1.4, namely that the Pieri formula and Order 2 imply Identity 2: If $\zeta \cdot \eta$ is a disjoint product, then $[1, \zeta] \preceq$ and $[1, \eta] \preceq$ have disjoint sets of edge labels. Together with Theorem 1.4(4), this gives another proof of Theorem 3.4 in \cite{b}, that $F_{w \times u} = F_w \cdot F_u$.

To prove Theorem 3.8, we first study chains in $H_\alpha(P \times Q)$. Suppose that $P$ has rank $n$ and $Q$ has rank $m$. Note that a chain in $P \times Q$ determines and is determined by the following data:

1. A chain in each of $P$ and $Q$,
2. A subset $B$ of $\{1, \ldots, n + m\}$ with $\#B = n$.

Recall that covers $(p, q) \prec (p', q')$ in $P \times Q$ have one of two forms: either $p = p'$ and $q'$ covers $q$ in $Q$ or else $q = q'$ and $p'$ covers $p$ in $P$. Thus a chain in $P \times Q$ gives a chain in each of $P$ and $Q$, with the covers from $P$ interspersed among the covers from $Q$. If we set $B$ to be the positions of the covers from $P$, we obtain the description (4). Define

\[ \text{sort} : \text{chains}(P \times Q) \longrightarrow \text{chains}(P) \times \text{chains}(Q) \]

to be the map which forgets the positions $B$ of the covers from $P$.
**Lemma 3.9.** Let $P$ and $Q$ be labeled posets with disjoint sets of edge labels and $\alpha$ be any composition. Then

$$\text{sort} : H_\alpha(P \times Q) \rightarrow \coprod_{\beta + \gamma = \alpha} H_\beta(P) \times H_\gamma(Q)$$

is a bijection.

For integers $a < b$, let $[a, b] := \{n \in \mathbb{Z} \mid a \leq n \leq b\}$. For a chain $\xi$, let $\xi|_{[a, b]}$ be the portion of $\xi$ starting at the $a$th step and continuing to the $b$th step.

**Proof.** Let $\xi \in H_\alpha(P \times Q)$ and set $I = I(\alpha)$ so that $I_i = \alpha_1 + \cdots + \alpha_i$. Then $\text{sort}(\xi) \in H_\beta(P) \times H_\gamma(Q)$, where, for each $i$, $\beta_i$ counts the number of covers of $\xi|_{[I_{i-1}, I_i]}$ from $P$ and $\gamma_i = \alpha_i - \beta_i$.

To see this is a bijection, we construct its inverse. For chains $\xi^P \in H_\beta(P)$ and $\xi^Q \in H_\gamma(Q)$ with $\beta + \gamma = \alpha$, define the set $B$ by the conditions

1. $\beta_i = \#B \cap [I(\alpha)_{i-1}, I(\alpha)_i]$.
2. If $b_1 \leq \cdots \leq b_{\beta_i}$ and $c_1 \leq \cdots \leq c_{\gamma_i}$ are the covers in $\xi^P|_{[I(\beta)_{i-1}, I(\beta)_i]}$ and $\xi^Q|_{[I(\gamma)_{i-1}, I(\gamma)_i]}$ respectively, then, up to a shift of $I(\alpha)_{i-1}$, the set $B \cap [I(\alpha)_{i-1}, I(\alpha)_i]$ records the positions of the the $b$'s in the linear ordering of $\{b_1, \ldots, b_{\beta_i}, c_1, \ldots, c_{\gamma_i}\}$.

This clearly gives the inverse to the map sort. $\blacksquare$

Recall that the comultiplication $\Delta : \Lambda \rightarrow \Lambda \otimes \Lambda$ is defined by

$$\Delta(h_a) = \sum_{b+c=a} h_b \otimes h_c.$$ 

Thus, for a composition $\alpha$,

$$\Delta(h_\alpha) = \sum_{\beta + \gamma = \alpha} h_\beta \otimes h_\gamma.$$

From Lemma 3.9, we immediately deduce:

**Corollary 3.10.** Let $P, Q$ be symmetric labeled posets with disjoint sets of edge labels. Then

$$\Delta : \chi_{P \times Q} \rightarrow \chi_P \otimes \chi_Q \otimes \chi_P \otimes \chi_Q$$

commutes.

**Corollary 3.11.** Let $P, Q$ be symmetric labeled posets with disjoint sets of edge labels. Then, for any partition $\lambda$,

$$c^P \times Q = \sum_{\mu, \nu} c^\lambda_{\mu, \nu} c^P_\mu c^Q_\nu.$$
Proof. Recall [25, I.5.9] that \( \Delta(S_{\lambda}) = \sum_{\mu, \nu} c_{\mu \nu}^\lambda S_{\mu} S_{\nu} \). Hence
\[
\chi_{P \times Q}(S_{\lambda}) = \sum_{\mu, \nu} c_{\mu \nu}^\lambda \chi_P(S_{\mu}) \chi_P(S_{\nu}).
\]

We complete the proof of Theorem 3.8: Let \( P, Q \) be symmetric labeled posets with disjoint sets of edge labels. Then
\[
S_P \cdot S_Q = \sum_{\mu, \nu} c_{\mu \nu}^P S_{\mu} c_{\nu}^Q S_{\nu} = \sum_{\lambda, \mu, \nu} c_{\mu \nu}^\lambda c_{\mu}^P c_{\nu}^Q S_{\lambda} = \sum_{\lambda} c_{\lambda P \times Q}^\lambda S_{\lambda} = S_{P \times Q}.
\]

4. STANLEY SYMMETRIC FUNCTIONS FROM LABELED POSETS

We establish Theorem 1.4(4) by adapting the proof of the Littlewood-Richardson rule in [28] to obtain a bijective interpretation of the constants \( c_{\lambda \mu \nu}^{[1, w]_{\text{weak}}} \), which shows \( S_{[1, w]_{\text{weak}}} = F_w \) by the formulas in [22, 9]. The main tool is a jeu de taquin for reduced decompositions.

We use Cartesian conventions for Young diagrams and skew diagrams. Thus the first row is at the bottom. A filling of a diagram \( D \) with positive integers which increase across rows and up columns is a tableau with shape \( D \). The word of a tableau is the sequence of its entries, read across each row starting with the topmost row.

A reduced decomposition \( \rho \) for a permutation \( w \in S_\infty \) is the word of a maximal chain in \([1, w]_{\text{weak}}\). Let \( R(w) \) be the set of all reduced decompositions for \( w \) and for a composition \( \alpha \) of \( \ell(w) \), write \( H_\alpha(w) \) for \( H_\alpha([1, w]_{\text{weak}}) \). Given any composition \( \alpha \) and any reduced decomposition \( \rho \in H_\alpha(w) \), there is a unique smallest diagram \( \lambda/\mu \) with row lengths \( \lambda_i - \mu_i = \alpha_{k+1-i} \) for which \( \rho \) is the word of a tableau \( T(\alpha, \rho) \) of shape \( \lambda/\mu \). By this we mean that \( \mu_j - \mu_{j+1} \) is minimal for all \( j \). If \( \mu_1 = 0 \), then \( T(\alpha, \rho) \) has partition shape \( \lambda (= \alpha) \), otherwise \( T(\alpha, \rho) \) has skew shape. Given a reduced decomposition \( \rho \in R(w) \), define \( T(\rho) \) to be the tableau \( T(\alpha, \rho) \), where \( I(\alpha) \) is the descent set of \( \rho \).

Stanley [30] defined a symmetric function \( F_w \) for every \( w \in S_\infty \). (That \( F_w \) is symmetric includes a proof that the intervals \( [1, w]_{\text{weak}} \) are symmetric.) Thus there exists integers \( a_\lambda^w \) such that
\[
F_w = \sum_{\lambda} a_\lambda^w S_{\lambda}.
\]
A combinatorial interpretation for \( a_\lambda^w \) was given (independently) in [22] and [3]:
\[
a_\lambda^w = \#\{ \rho \in R(w) \mid T(\rho) \text{ has partition shape } \lambda \}.
\]
(See [24, §VII] for an account with proofs.) Theorem 1.4(4) is a consequence of the following result:
Theorem 4.1. For any $w \in S_{\infty}$ and partition $\lambda \vdash \ell(w)$,
\[
a_{\lambda}^w = c_{[1,w]}^{weak}.
\]

Our proof is based on the proof of the Littlewood-Richardson rule given by Remmel and Shimozono \[28\]. We define an involution $\theta$ on the set
\[
\prod_{\pi \in S_k} \{\pi\} \times H_{\lambda_{w}}(w)
\]
(here $\lambda \vdash \ell(w)$ and $\lambda_{k+1} = 0$) such that
1. $\theta(\pi, \rho) = (\pi, \rho)$ if and only if $T(\rho)$ has shape $\lambda$, from which it follows that $\pi = 1$.
2. If $T(\rho)$ does not have shape $\lambda$, then $\theta(\pi, \rho) = (\pi', \rho')$ where $T(\rho')$ does not have shape $\lambda$ and $\rho' \in H_{\lambda_{w}}(w)$ with $|\ell(\pi) - \ell(\pi')| = 1$.

Theorem 4.1 is a corollary of the existence of such an involution $\theta$: By property 2, only the fixed points of $\theta$ contribute to the sum in Lemma 3.2(1).

The involution $\theta$ will be defined using a jeu de taquin for tableaux whose words are reduced decompositions. Because we only play this jeu de taquin on diagrams with two rows, we do not describe it in full.

Definition 4.2. Let $T$ be a tableau of shape $(y + p, q)/(y, 0)$ whose word is a reduced decomposition for a permutation $w$. If $y \neq 0$, we may perform an inward slide. This modification of an ordinary jeu de taquin slide ensures we obtain a tableau whose word is a reduced decomposition of $w$.

Begin with an empty box at position $(y, 1)$ and move it through the tableau $T$ according to the following local rules:

1. If the box is in the first row, it switches with whichever of its neighbors to the right or above is smaller.

   If both neighbors are equal, say they are $a$, then their other neighbor is necessarily $a+1$, as we have a reduced decomposition. Locally we will have the following configuration, where $\blacksquare$ denotes the empty box and $a + b + 1 < c$:

\[
\begin{array}{cccccccc}
  a & a+1 & a+2 & \cdots & a+b & a+b+1 \\
\blacksquare & a & a+1 & \cdots & a+b & c
\end{array}
\]

The empty box moves through this configuration, transforming it into:

\[
\begin{array}{cccccccc}
a+1 & a+2 & \cdots & a+b+1 \\
a+1 & a+1 & \cdots & a+b & a+b+1 & c
\end{array}
\]

This guarantees that we still have a reduced decomposition for $w$.

2. If the box is in the second row, then it switches with its neighbour to the right.

   If $y+p > q$, then we may analogously perform an outward slide, beginning with an empty box at $(q+1, 2)$ and sliding to the left or down according to local rules that are the reverse of those for the inward slide.

We note some consequences of this definition.
The box will change rows at the first pair of entries \( b \leq c \) it encounters with \( b \) at \((i, 2)\) and \( c \) immediately to its lower right at \((i + 1, 1)\). If there is no such pair, it will change rows at the end of the first row in an inward slide if \( p + y = q \), and at the beginning of the second row in an outward slide if \( y = 0 \).

At least one of these will occur if \( y \) is minimal given the word of the tableau and \( p, q \). Suppose this is the case. Then the tableau \( T' \) obtained from a slide will have another such pair \( b' \leq c' \) with \( b' \) at \((i', 2)\) and \( c' \) at \((i' + 1, 1)\). Hence, if we perform a second slide, the box will again change rows.

The inward and outward slides are inverses.

Let \( H_\alpha(w) \) be the subset of \( H_\alpha(w) \) consisting of chains \( \rho \) such that \( T(\alpha, \rho) \) has skew shape. The proof of the following lemma is straightforward.

**Lemma 4.3.** Let \( w \in S_\infty \) and suppose \( p < q \) with \( p + q = \ell(w) \). Then \( H_{(q,p)}(w) = \overline{H}_{(q,p)}(w) \) and

1. For every \( \rho \in H_{(q,p)}(w) \), we may perform \( q - p \) inward slides to \( T((q,p), \rho) \). If \( \rho' \) is the word of the resulting tableau, then the map \( \rho \mapsto \rho' \) defines a bijection
   \[ H_{(q,p)}(w) \leftrightarrow H_{(p,q)}(w). \]
   The inverse map is given by the application of \( q - p \) outward slides.

2. If we now let \( \rho' \) be the word of the tableau obtained after \( q - p - 1 \) inward slides to \( T((q,p), \rho) \) for \( \rho \in H_{(q,p)}(w) \), then the map \( \rho \mapsto \rho' \) defines a bijection
   \[ \overline{H}_{(q,p)}(w) \leftrightarrow \overline{H}_{(p+1,q-1)}(w). \]
   The inverse map is defined by the application of \( q - 1 - p \) outward slides.

The first part gives a proof that intervals in the weak order are symmetric: Let \( \alpha = (\alpha_1, \ldots, \alpha_k) \) and \( \alpha' = (\alpha_1, \ldots, \alpha_{r+1}, \alpha_r, \ldots, \alpha_k) \) be compositions of \( \ell(w) \). Then applying the bijection in Lemma 4.3 to the segment \( \rho_r \) of \( \rho \in H_\alpha(w) \) between \( I(\alpha)_{r-1} \) and \( I(\alpha)_{r+1} \) defines a bijection

\[ H_\alpha(w) \leftrightarrow H_{\alpha'}(w). \]

**Remark 4.4.** This bijection is different from the one used in [30] to prove symmetry of these intervals. Indeed, consider the example given there, which we write as a tableau:

\[
\begin{array}{cccccccccccccccc}
1 & 2 & 3 & 7 & 8 & 9 & 10 & 11 & 13 & 16 & 17 & 18 & 19 & 21 & 22 \\
1 & 4 & 5 & 6 & 7 & 8 & 12 & 13 & 14 & 15 & 16 & 20 & 21 \\
\end{array}
\]

In [30], Stanley maps this to

\[
\begin{array}{cccccccccccccccc}
1 & 2 & 3 & 7 & 8 & 9 & 10 & 11 & 13 & 16 & 17 & 21 & 22 \\
1 & 4 & 5 & 6 & 7 & 8 & 12 & 13 & 14 & 15 & 16 & 18 & 19 & 20 & 21 \\
\end{array}
\]

But the bijection we define gives us this:

\[
\begin{array}{cccccccccccccccc}
2 & 7 & 8 & 9 & 10 & 11 & 13 & 16 & 17 & 18 & 19 & 21 & 22 \\
1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 12 & 13 & 14 & 15 & 16 & 20 & 21 \\
\end{array}
\]
Now we may define \( \theta \). By the definition of \( \lambda \), if \( \rho \in H_{\lambda \pi}(w) \), then \( T(\rho) \) has shape \( \lambda \) if and only if \( T(\lambda \pi, \rho) \) has partition shape, which implies that \( \pi = 1 \).

**Definition 4.5.** Suppose \( w \in S_\infty \) and \( \lambda \vdash \ell(w) \) is a partition with \( \lambda_{k+1} = 0 \). Let \( \pi \in S_k \).

For \( \rho \in H_{\lambda \pi}(w) \), define \( \theta(\pi, \rho) \) as follows:

1. If \( T(\rho) \) has shape \( \lambda \), set \( \theta(\pi, \rho) = (\pi, \rho) \). In this case, \( \pi = 1 \), so \( \lambda \pi = \lambda \) and \( T(\rho) = T(\lambda \pi, \rho) \).
2. If \( T(\rho) \) does not have shape \( \lambda \), then \( T(\lambda \pi, \rho) \) has skew shape and we select \( r = r(T(\lambda \pi, \rho)) \) with \( 1 \leq r < k \) as follows:

   - Left justify the rows of \( T(\lambda \pi, \rho) \). Since \( T(\lambda \pi, \rho) \) has skew shape, there is an entry \( a \) of this left-justified figure in position \((i, r + 1)\) either with no entry in position \((i, r)\) just below it, or else with an entry \( b \geq a \) just below it. Among all such \((i, r)\) choose the one with \( i \) minimal, and for this \( i, r \) maximal.

   - Let \( \rho_r \) be the word given by the rows \( r + 1 \) and \( r \) of \( T(\lambda \pi, \rho) \) and \((q, p)\) the lengths of these two rows. Then \( T((q, p), \rho_r) \) has skew shape, and we may apply the map of Lemma 4.3(2) to obtain the word \( \rho'_r \). Define \( \theta(\pi, \rho) = (\pi', \rho') \), where \( \rho' \) is the word obtained from \( \rho \) by replacing \( \rho_r \) with \( \rho'_r \) and \( \pi'(r, p^{-1} = (r, r+1) \). Note that \( T(\lambda \pi, \rho') \) also has skew shape and \( T(\rho') \) does not have shape \( \lambda \).

**Example 4.6.** Let \( w = 4621357 \) and \( \lambda = (4, 3, 3, 1) \). Then \( \rho = 5.345.236.1236 \in H_{\lambda}(w) \) but

\[
T(\lambda, \rho) = \begin{bmatrix}
5 & 3 & 4 & 5 \\
2 & 3 & 6 \\
1 & 2 & 3 & 5
\end{bmatrix}
\]

has skew shape. Left-justifying the rows of \( T(\lambda, \rho) \), we obtain:

\[
\begin{bmatrix}
5 \\
3 & 4 & 5 \\
2 & 3 & 6 \\
1 & 2 & 3 & 5
\end{bmatrix}
\]

This is not a tableau, as the third column reads 365, which is not increasing. Since this is the first such column and the last decrease is at position 2, we have \( r = 2 \). Since these two rows each have length 3, we perform one outward slide (by our choice of \( r \), we can perform such a slide!) to obtain the tableau \( T((4, 2), \rho'_r) \) as follows:

\[
\begin{bmatrix}
3 & 4 & 5 \times \\
2 & 3 & 6
\end{bmatrix} \rightarrow \begin{bmatrix}
3 & 4 & 5 & 6 \\
2 & 3 \times
\end{bmatrix} \rightarrow \begin{bmatrix}
3 & 4 & 5 & 6 \\
\times & 2 & 3
\end{bmatrix}
\]
Thus \( \rho' = 5.3456.23.1235 \in H_{\lambda(2,3)}(w) \). If we left justify \( T(\lambda(2,3), \rho') \), then we obtain:

\[
\begin{array}{cccc}
3 & 4 & 5 & 6 \\
2 & 3 \\
1 & 2 & 3 & 5 \\
\end{array}
\]

The 5 in the third row has no lower neighbour, hence \( 2 = r(\lambda, \rho) = r(\lambda(2,3), \rho') \).

We complete the proof of Theorem 4.1 by showing that \( \theta \) is an involution. This is a consequence of Lemma 4.7 and the following fact:

**Lemma 4.7.** In (2) of Definition 4.3, if \( \rho \in H_{\lambda}(w) \) and \( T(\lambda_{\pi}, \rho) \) has skew shape, then \( r(T(\lambda_{\pi}, \rho)) = r(T(\lambda_{\pi'}, \rho')) \).

**Proof.** Suppose we are in the situation of (2) in Definition 4.3. The lemma follows once we show that that \( T((q, p), \rho_{\pi}) \) and \( T((p + 1, q - 1), \rho'_{\pi}) \) agree in the first \( i \) entries of their second rows, the first \( i - 1 \) entries of their first rows, and the \( j \)th entry \( c \) in the first row of \( T((p + 1, q - 1), \rho'_{\pi}) \) satisfies \( a \leq c \), or else there is no \( i \)th entry.

In fact, we show this holds for each intermediate tableau obtained from \( T((q, p), \rho) \) by some of the slides used to form \( T((p + 1, q - 1), \rho') \).

We argue in the case that \( p < q \), that is, for inward slides. Suppose that \( T \) is an intermediate tableau satisfying the claim, and that the tableau \( T' \) obtained from \( T \) by a single inward slide is also an intermediate tableau. It follows that \( T' \) has skew shape, so that if \( (y + s, t)/(y, 0) \) is the shape of \( T \), then \( y > 1 \).

Suppose that during the slide the box changes rows at the \( j \)th column. We claim that \( j \geq i + y - 1(> i) \). If this occurs, then the first \( i \) entries in the second row and first \( i - 1 \) entries in the first row of \( T \) are unchanged in \( T' \). Also, the \( i \)th entry in the first row of \( T' \) is either the \( i \)th entry in the first row of \( T \) (if \( j \geq i + y \)) or it is the \( j \)th entry in the second row of \( T \), which is greater than the \( i \)th entry, \( a \). Thus showing \( j \geq i + y - 1 \) completes the proof.

To see that \( j \geq i + y - 1 \) note that if \( j \) is the last column, then \( j = t = s + y \). Since \( s \geq i - 1 \), we see that \( j \geq y + i - 1 \). If \( j \) is not the last column, then the entries \( b \) at \( (j + 1, 1) \) of \( T \) satisfy \( b \leq c \). Suppose that \( j < i + y - 1 \). Then \( c \) is the \( (j + y - 1) \)th entry in the first row of \( T \). Since \( j - y + 1 < i \), our choice of \( i \) ensures that \( c \) is less than the entry at \( (j - y + 1, 2) \) of \( T \). Since \( j - y + 1 < j \), this in turn is less than \( b \), a contradiction.

Similar arguments suffice for the case when \( p \geq q \). 

**Remark 4.8.** While it may seem this proof has only a formal relation to the proof of Remmel and Shimozono [28], it is in fact nearly an exact translation—the only difference being in our choice of \( r \). (Their choice of \( r \) is not easily expressed in this setting.) We elaborate.

The exact same proof, but with the ordinary *jeu de taquin*, shows that \( c^{[\mu, \lambda)]}_{\nu} \) counts the chains in \([\mu, \lambda]_{\subset}\) whose word is the word of a tableau of shape \( \nu \). This is just the Littlewood-Richardson coefficient \( c^{\lambda}_{\mu, \nu} \). One way to see this is to consider the bijection
between $H_\alpha([\mu, \lambda]_C)$ and the set of semistandard Young tableaux of shape $\lambda/\mu$ and content $(\nu_k, \ldots, \nu_1)$. The chains whose word is the word of a tableau of shape $\nu$ correspond to reverse LR tableaux of shape $\lambda/\mu$, which are defined as follows:

Let $f_{a,b}(T)$ be the number of $a$’s in the first $b$ positions of the word of $T$. A reverse LR tableau $T$ with largest entry $k$ is a tableau satisfying:

$$f_{1,b}(T) \leq f_{2,b}(T) \leq \cdots \leq f_{k,b}(T)$$

for all $b$. It is an exercise to verify that there are exactly $c^\lambda_{\nu}$ reverse LR tableaux of shape $\lambda/\mu$ and content $(\nu_k, \ldots, \nu_2, \nu_1)$.

The choice we make of $i$ and $r$ is easily expressed in these terms: $i$ is the minimum value of $f_{a,b}(T)$ among all violations $f_{a,b}(T) > f_{a+1,b}(T)$, and if $a$ is the minimal first index among all violations with $f_{a,b}(T) = i$, then $r = k - a$. The choice in [28] for reverse LR tableaux would be $r = k - a$, where $f_{a,b}(T)$ is the violation with minimal $b$.

The key step we used was the jeu de taquin whereas Remmel and Shimozono used an operation built from the $r$-pairing of Lascoux and Schützenberger [20]. In fact, this too is a direct translation.

The reason for this is, roughly, that the passage from the word of a chain $\rho \in H_\alpha([\mu, \lambda]_C)$ to a semistandard Young tableau of shape $\lambda/\mu$ and content $(\alpha_k, \ldots, \alpha_1)$ (which interchanges shape with content) also interchanges Knuth equivalence and dual Knuth equivalence [13]. The operators constructed from the $r$-pairing preserve the dual equivalence class of a 2-letter word but alter its content. In fact, this property characterizes such an operation.

As shown in [13], there is at most one tableau in a given Knuth equivalence class and a given dual equivalence class. Also, for semistandard Young tableaux with at most 2 letters, there is at most one tableau with given partition shape and content. It follows that any operation on tableaux acting on the subtableau of entries $r, r + 1$ which preserves the dual equivalence class of the subtableau, but reverses its content is uniquely defined by these properties.

Thus the symmetrization operators in [20], which generate an $S_\infty$-action on tableaux extending the natural action on their contents, is unique. Expressed in this form, we see that this action coincides with one introduced earlier by Knuth [15]. This action was the effect of permuting rows of a matrix on the $P$-symbol obtained from that matrix by Knuth’s generalization of the Robinson-Schensted correspondence. The origin of these symmetrization operators in the work of Knuth has been overlooked by most authors, perhaps because Bender-Knuth [1] later use a different operation to prove symmetry.

For each poset $P$ in the classes of labeled posets we consider here, the symmetric function $S_P$ is Schur-positive. When $P$ is an interval in some $k$-Bruhat order, this follows from geometry, for intervals in Young’s lattice, this is a consequence of the Littlewood-Richardson rule, and for intervals in the weak order, it is due to Lascoux-Schützenberger [21] and Edelman-Greene [9]. Is there a representation-theoretic explanation? In particular, we ask:

**Question:** If $P$ is an interval in a $k$-Bruhat order, can one construct a representation $V_P$ of $S_{\text{rank}P}$ so that $S_P$ is its Frobenius character? More generally, for a labeled poset $P$, can
one define a (virtual) representation $V_P$ so that $S_P$ is its Frobenius character? If so, is $V_P \times Q \simeq V_P \otimes V_Q$?

When $P$ is an interval in Young’s lattice this is a skew Specht module. For an interval $[1, w]_{\text{weak}}$ in the weak order, Kr´ askiewicz [17] constructs a $S_{\ell(w)}$-representation of dimension $\#R(w)$. For general linear group representations, such a construction is known. For intervals in the weak order, this is due to Kr´ askiewicz and Pragacz [18].

5. The monomials in a Schubert polynomial

We give a new proof based upon geometry that a Schubert polynomial is a sum of monomials with non-negative coefficients. This analysis leads to a combinatorial construction of Schubert polynomials in terms of chains in the Bruhat order. It also shows these coefficients are certain intersection numbers, essentially the same interpretation found by Kirillov and Maeno [14].

The first step is Theorem 5.1, which generalizes both Proposition 1.7 of [22] and Theorem C (ii) of [3]. Recall that $u \overset{r[m,k]}{\rightarrow} w$ when one of the following equivalent conditions holds:

- $c_{u_r, r[m,k]}^w = 1$.
- $u \leq_k w$ and $wu^{-1}$ is a disjoint product of increasing cycles.
- There is an chain in $[u, w]_k$:
  
  $u \overset{b_1}{\rightarrow} u_1 \overset{b_2}{\rightarrow} \cdots \overset{b_m}{\rightarrow} u_m = w$

  with $b_1 < b_2 < \cdots < b_m$.

For $p \in \mathbb{N}$, define the map $\Phi_p : \mathbb{Z}[x_1, x_2, \ldots] \rightarrow \mathbb{Z}[y] \otimes \mathbb{Z}[x_1, x_2, \ldots]$ by

$$\Phi_p(x_i) = \begin{cases} 
  x_i & \text{if } i < p \\
  y & \text{if } i = p \\
  x_{i-1} & \text{if } i > p
\end{cases}$$

For $w \in S_{\infty}$ and $p, q \in \mathbb{N}$, define $\varphi_{p,q}(w) \in S_{\infty}$ by

$$\varphi_{p,q}(w)(j) = \begin{cases} 
  w(j) & j < p \text{ and } w(j) < q \\
  w(j) + 1 & j < p \text{ and } w(j) \geq q \\
  q & j = p \\
  w(j - 1) & j > p \text{ and } w(j) < q \\
  w(j - 1) + 1 & j > p \text{ and } w(j) \geq q
\end{cases}$$

Representing permutations as matrices, $\varphi_{p,q}$ adds a new $p$th row and $q$th column consisting mostly of zeroes, but with a 1 in the $(p, q)$th position. For example,

$$\varphi_{3,3}(23154) = 243165 \quad \text{and} \quad \varphi_{2,5}(2341) = 25342.$$

Theorem 5.1. For $u \in S_n$,

$$\Phi_p \mathcal{S}_u = \sum_{j, w \text{ with } u \overset{r[n+1-p-j,q]}{\rightarrow} \varphi_{p,n+1}(w)} y^j \mathcal{S}_w(x).$$
Moreover, if $n$ is not among $\{u(1), \ldots, u(p-1)\}$, then the sum may be taken over those $j, w$ with $u \overset{r[n-p-j,p]}{\rightarrow} \varphi_{p,n}(w)$.

Iterating this gives another proof that the monomials in a Schubert polynomial have non-negative coefficients.

**Example 5.2.** Consider $\Phi_2 S_{13542}$. We display all increasing chains in the 2-Bruhat order on $S_5$ above 13542 whose endpoint $w$ satisfies $w(2) = 5$:

\[ 25431 \]
\[ 24531 \quad 25341 \quad 15432 \quad 23541 \quad 14532 \quad 15342 \]
\[ 25431 \quad 14532 \quad 15432 \quad 23541 \]
\[ 13542 \]

We see therefore that

\[
\begin{align*}
13542 & \overset{[3,2]}{\rightarrow} 25431 = \varphi_{2,5}(2431), \\
13542 & \overset{[2,2]}{\rightarrow} 25341 = \varphi_{2,5}(2341), \\
13542 & \overset{[2,2]}{\rightarrow} 15432 = \varphi_{2,5}(1432), \\
13542 & \overset{[1,2]}{\rightarrow} 15342 = \varphi_{2,5}(1342).
\end{align*}
\]

Then Theorem 5.1 asserts that

\[
\Phi_2 S_{13542} = S_{2431}(x) + y S_{2341}(x) + y S_{1432}(x) + y^2 S_{1342}(x),
\]

which may also be verified by direct calculation.

**Proof of Theorem 5.1.** We make two definitions. For $p \leq n$, define another map $\psi_{p,[n]} : S_n \times S_m \hookrightarrow S_{n+m}$ by

\[
\psi_{p,[n]}(w,z)(i) = \begin{cases} 
 w(i) & i < p \\
 n + z(1) & i = p \\
 w(i-1) & p < i \leq n + 1 \\
 n + z(i-n) & n + 1 < i \leq n + m
\end{cases}
\]

Then $\psi_{p,[n]}(1,1) = r[n+1-p,p]$.

Let $P \subset \{1, 2, \ldots, n+m\}$ and suppose that

\[
P = p_1 < p_2 < \cdots < p_n,
\]

\[
\{1, \ldots, n+m\} - P = q_1 < q_2 < \cdots < q_m.
\]

Define the map $\Psi_p : \mathbb{Z}[x_1, x_2, \ldots, x_{n+m}] \rightarrow \mathbb{Z}[x_1, \ldots, x_n] \otimes \mathbb{Z}[y_1, \ldots, y_m]$ by

\[
\Psi_p(x_i) = \begin{cases} 
 x_j & \text{if } i = p_j \\
 y_j & \text{if } i = q_j
\end{cases}
\]
Suppose now that $P = \{1, 2, \ldots, p - 1, p + 1, \ldots, n + 1\}$. Then for $u \in S_{n+m}$, Theorem 4.5.4 of [3] asserts that

$$
\Psi_P S_u \equiv \sum_{w \in S_n, z \in S_m} c_{u, r[n+1-p]}^\psi S_w(x) \otimes S_z(y),
$$

modulo the ideal $\langle S_w(x) \otimes z, S_z(y) \mid w \not\in S_n, z \not\in S_m \rangle$ which is equal to the ideal $\langle x^\alpha \otimes 1, 1 \otimes y^\alpha \mid \alpha_i \geq n - i \text{ for some } i \rangle$. (The calculation is in the cohomology of the product of flag manifolds $\text{Flags}(\mathbb{C}^n) \times \text{Flags}(\mathbb{C}^m)$.)

Suppose now that $u \in S_n$ and $m \geq n$. Then (6) is an identity of polynomials, and not just of cohomology classes. We also see that $\Psi_P S_u = \Phi_p S_u$, since $S_u \in \mathbb{Z}[x_1, \ldots, x_n]$. By the Pieri formula,

$$
c_{u, r[n+1-p]}^\psi = \begin{cases} 
1 & \text{if } u \overset{r[n+1-p]}{\rightarrow} \psi, \\
0 & \text{otherwise}.
\end{cases}
$$

Since $u \leq_p \psi$ and $u(n + i) = n + i$, Definition [1] (2) (for $u \leq_p \psi$) implies that $\psi_u^1(w, z)(n + 1) < \psi_u^2(w, z)(n + 2) < \cdots$. Thus by the definition (2) of $\psi_u$, we have $z(2) < z(3) < \cdots$, and so $z$ is the Grassmann permutation $r[z(1) - 1, 1]$. Hence $S_z(y) = y^{z(1) - 1}$.

If we set $j = z(1) - 1$, then $\psi_{j+1}(w, z) = \varphi_{p,n+1+j}(w)$. Thus, for $u \in S_n$, we have

$$
\Phi_p S_u = \sum_{j, w \text{ such that } u \overset{r[n+1-p]}{\rightarrow} \varphi_{p,n+1+j}(w)} y^j S_w(x).
$$

Suppose that $u \overset{r[n+1-p]}{\rightarrow} \varphi_{p,n+1+j}(w)$. Consider the unique increasing chain in the interval $[u, \varphi_{p,n+1+j}(w)]_P$:

$$
u = u_0 \overset{b_1}{\rightarrow} \cdots \overset{b_{n-p}}{\rightarrow} u_{n-p-j} \overset{b_{n+1-p}}{\rightarrow} \cdots \overset{b_{n+p}}{\rightarrow} \varphi_{p,n+1+j}(w),
$$

Because $u \in S_n$, we must have $b_{n+1-p} = n + 1$ and so $u_{n+1-p-j} = \varphi_{p,n+1}(w)$. Moreover, if $n$ is not among $\{u(1), \ldots, u(p)\}$, then we have $b_{n-p-j} = n$ and so $u_{n-p-j} = \varphi_{p,n}(w)$. If $u(p) = n$, then we also have $u_{n-p-j} = \varphi_{p,n}(w)$. This completes the proof.

Define $\delta$ to be the sequence $(n - 1, n - 2, \ldots, 1, 0)$.

**Corollary 5.3.** For $w \in S_n$ and $\alpha < \delta$, the coefficient of $x^{\delta - \alpha}$ in $S_w$ is the number of chains

$$
\begin{align*}
&x^{\delta - \alpha} = \omega_0 \\
\end{align*}
$$

in the Bruhat order, where, for each $1 \leq k \leq n - 1$,

$$
\begin{align*}
&x^{\alpha_1 + \cdots + \alpha_{k-1}} \overset{k}{\rightarrow} x^{\alpha_1 + \cdots + \alpha_{k-1} + \alpha_k} \\
\end{align*}
$$

is an increasing chain in the $k$-Bruhat order.
Example 5.4. Here are all such chains in $S_4$ from 1432 to 4321, with the index $\alpha$ displayed above each chain:

\[
\begin{array}{cccccc}
111 & 120 & 201 & 210 & 300 \\
4321 & 4321 & 4321 & 4321 & 4321 \\
4312 & 4231 & 4312 & 4231 & 3421 \\
4132 & 3412 & 2431 & & & \\
& & & & & 1432 \\
\end{array}
\]

From this, we see that
\[
S_{1432} = x^{321-111} + x^{321-120} + x^{321-201} + x^{321-210} + x^{321-300} \\
= x_1^2 x_2 + x_1^2 x_3 + x_1 x_2^2 + x_1 x_2 x_3 + x_2^2 x_3.
\]

Proof. Repeatedly applying $\Phi$ and iterating Theorem 5.1, we see that the coefficient of $x^{\delta-\alpha}$ in $S_w(x)$ is the number of chains
\[
w < w_1 < w_2 < \cdots < w_{\alpha_1 + \cdots + \alpha_{n-1}} = \omega_0
\]
which satisfy the conditions of the corollary, together with the (apparent) additional requirement that, for each $k < n$,
\[
w_{\alpha_1 + \cdots + \alpha_k}(j) = n + 1 - j \text{ for all } j \leq k.
\]
The corollary will follow, once we show this is no additional restriction.

First note that if $u \xrightarrow{r[a,k]} u'$ with $u'(j) = n + 1 - j$ for $1 \leq j \leq k$, but $u(i) < n + 1 - i$ for some $1 \leq i \leq k$, then $i = k$. To see this, note that since $u \leq_k u'$, the form of $u'$ and Definition [1.1] (2) implies that $u(1) > u(2) > \cdots > u(k)$. Set $\zeta = u'u^{-1}$. Since $u \xrightarrow{r[a,k]} u'$, $\zeta$ is a disjoint product of increasing cycles, hence their supports are non-crossing. Suppose $i < k$. Then $\{u(i), n + 1 - i = u'(i)\}$ and $\{u(i + 1), n - i = u'(i + 1)\}$ are in the support of distinct cycles. However, $u(i + 1) < u(i) \leq n - i < n + 1 - i$ contradicts that these supports are non-crossing, so we must have $i = k$.

Let
\[
w < w_1 < w_2 < \cdots < w_{\alpha_1 + \cdots + \alpha_{n-1}} = \omega_0
\]
be a chain that satisfies the conditions of the corollary. We prove that (8) holds for all $k < n$ by downward induction. Since $\omega_0 = w_{\alpha_1 + \cdots + \alpha_{n-1}}$, we see that (8) holds for $k = n - 1$. Suppose that (8) holds for some $k$. Set $u = w_{\alpha_1 + \cdots + \alpha_{k-1}}$ and $u' = w_{\alpha_1 + \cdots + \alpha_k}$. Then $u \xrightarrow{r[\alpha_k,k]} u'$ with $u'(j) = n + 1 - j$ for $1 \leq j \leq k$. By the previous paragraph, we must have $u(i) = n + 1 - i$ for all $i < k$, hence (8) holds for $k - 1$. \(\square\)

We could also have written the coefficient of $x^{\delta-\alpha}$ in $S_w(x)$ as the number of chains
\[
w \xrightarrow{r[\alpha_1,1]} w_1 \xrightarrow{r[\alpha_2,2]} w_2 \xrightarrow{r[\alpha_3,3]} \cdots \xrightarrow{r[\alpha_{n-1},n-1]} \omega_0
\]
in $S_n$. From this and the Pieri formula for Schubert polynomials, we obtain another description of these coefficients. First, for $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_{n-1})$ with $\alpha_i \geq 0$, let $h(\alpha)$ denote the product of complete homogeneous symmetric polynomials
\[
h_{\alpha_1}(x_1)h_{\alpha_2}(x_1, x_2) \cdots h_{\alpha_{n-1}}(x_1, x_2, \ldots, x_{n-1}).
\]

**Corollary 5.5.** For $w \in S_n$,
\[
S_w = \sum_{\alpha} d^w_{\alpha} x^{\delta - \alpha}
\]
where $d^w_{\alpha}$ is the coefficient of $S_{\omega_0}$ in the product $S_w \cdot h(\alpha)$.

This is essentially the same formula as found by Kirillov and Maeno [14] who showed that the coefficient of $x^{\delta - \alpha}$ in $S_w$ to be the coefficient of $S_{\omega_0}$ in the product $S_{\omega_0} \cdot e(\alpha)$, where
\[
e(\alpha) = e_{\alpha_{n-1}}(x_1)e_{\alpha_{n-2}}(x_1, x_2) \cdots e_{\alpha_1}(x_1, \ldots, x_{n-1}).
\]

To see these are equivalent, note that the algebra involution $S_w \mapsto S_{\pi w}$ on $H^*(\text{Flags}(\mathbb{C}^n))$ interchanges $e(\alpha)$ and $h(\alpha)$.

**Acknowledgments**

We thank Mark Shimozono and Richard Stanley for helpful comments. The second author is grateful to the hospitality of Université Genève and INRIA Sophia-Antipolis, where portions of this paper were developed and written.
