conley

COMPUTING CONNECTION MATRICES IN Maple

MOHAMED BARAKAT & DANIEL ROBERTZ

ABSTRACT. In this work we announce the Maple package conley to compute connection and $C$-connection matrices. conley is based on our abstract homological algebra package homalg. We emphasize that the notion of braids is irrelevant for the definition and for the computation of such matrices. We introduce the notion of triangles that suffices to state the definition of $(C)$-connection matrices. The notion of octahedra, which is equivalent to that of braids is also introduced.

1. Introduction

The algebraic theory of connection and C-connection matrices is concerned with condensing the information of a graded module octahedron in a matrix called a connection matrix or C-connection matrix.

In Section 2 we recall the central notions of this algebraic theory, introduce some new notions and give a braid-free definition of (C)-connection matrices. For this we introduce the notion of a graded module triangular system or simply a graded module triangle. This is the only notion used in the definition of connection and C-connection matrices.

The role of braids is emphasized in formulating the necessary and sufficient conditions to the existence of C-connection matrices in Section 3. There we also introduce the equivalent notion of octahedra.

The notion of symmetric C-connection matrix is defined in Section 4.

In Section 5 we briefly review the definition of the homology CONLEY index of an isolated invariant set and the theory of MORSE decompositions of a dynamical system. This theory is the main source of applications of connection matrices.

The package conley is more or less a tiny application of our more elaborate homological algebra package homalg [JR]. In Section 6 some technical comments on conley are made.

Finally, in Section 7 we present some simple examples using conley.

We are very much indebted to STANISLAUS MAIER-PAAPE, who initiated the joint CONLEY index seminar in Aachen, introduced us to the subject and explained us the fascinating dynamical side of the theory. We would also like to thank him for fruitful discussions which revealed a serious mistake in the first version of this paper. We also would like to thank all the participants of the seminar, and especially MAX NEUNHOEFFER and FELIX NOESKE for discussions about the algebraic aspects of the theory.

Aspects of dynamical systems are not in the focus of this paper. However, joint work with MAIER-PAAPE on more substantial dynamical applications and in particular on transition matrices [MM02, MPMW] is in preparation. Transition matrices can also be computed using conley. We don’t touch upon this theory here.

Note that we apply morphisms from the right and hence we use the row convention for matrices. As one consequence we talk about lower triangular instead of upper triangular matrices.

2. Connection Matrices

2.1. Posets. A set $P$ together with a strict partial order $>$ (i.e. an irreflexive and transitive relation $> \subset P \times P$) is called a poset and is denoted by $(P, >)$.

A subset $I \subset P$ is called an interval in $(P, >)$ if for all $p, q \in I$ and $r \in P$ the following implication holds:

$$q > r > p \quad \Rightarrow \quad r \in I.$$

The set of all intervals in $(P, >)$ is denoted by $\mathcal{I}(P, >)$.

An $n$-tuple $(I_1, \ldots, I_n)$ of intervals in $(P, >)$ is called adjacent if these intervals are mutually disjoint, $\bigcup_{i=1}^{n} I_i$ is an interval in $(P, >)$ and for all $p \in I_j$, $q \in I_k$ the following
implication holds:

\[ j < k \implies p \neq q. \]

The set of all adjacent \( n \)-tuples of intervals in \((P, >)\) is denoted by \( \mathcal{I}_n(P, >) \).

If \((I_1, \ldots, I_n)\) is an adjacent \( n \)-tuple of intervals in \((P, >)\), then set \( I_1 I_2 \ldots I_n := \bigcup_{i=1}^{n} I_i \).

If \((I, J) \in \mathcal{I}_2(P, >)\) as well as \((J, I) \in \mathcal{I}_2(P, >)\), then \( I \) and \( J \) are said to be noncomparable.

### 2.2. Triangles

For notions like quasi-isomorphism and distinguished triangles we refer to [GM03].

**Definition 2.1 (Graded module triangle).** Let \((P, >)\) be a poset. A graded module triangular system or simply a graded module triangle \( G \) over \((P, >)\) consists of graded modules \( G(I), I \in \mathcal{I}(P, >) \), and homomorphisms of graded modules

\[
\begin{align*}
i(I, IJ) : G(I) & \rightarrow G(IJ), \\
p(IJ, J) : G(IJ) & \rightarrow G(J), \\
\partial(J, I) : G(J) & \rightarrow G(I)
\end{align*}
\]

for all \((I, J) \in \mathcal{I}_2(P, >)\), where \( i(I, IJ) \) and \( p(IJ, J) \) are of degree 0, \( \partial(J, I) \) is of degree \(-1\), and the following two conditions are satisfied:

a) For all \((I, J) \in \mathcal{I}_2(P, >)\) the triangle

\[
\begin{CD}
G(I) @> i(I, IJ) >> G(IJ) @> p(IJ, J) >> G(J) @> \partial(J, I) >> G(I)
\end{CD}
\]

is distinguished.

b) If \( I, J \in \mathcal{I}(P, >) \) are noncomparable, then \( i(I, IJ)p(JJ, I) = \text{id}_{G(I)} \).

We think of a graded module as an element of \( \text{Kom}_0(A) \subset \text{Kom}(A) \). \( \text{Kom}(A) \) is the category of complexes over an abelian category \( A \) and \( \text{Kom}_0(A) \) the complete subcategory of cyclic complexes, i.e. complexes with zero boundary maps. Cf. [GM03, III.2.3].

The one dimensional unraveling of condition a) is the following long exact sequence condition:

a\') For all \((I, J) \in \mathcal{I}_2(P, >)\)

\[
\cdots \rightarrow G(I) \xrightarrow{i(I, IJ)} G(IJ) \xrightarrow{p(IJ, J)} G(J) \xrightarrow{\partial(J, I)} G(I) \rightarrow \cdots
\]

is a long exact sequence.

**Definition 2.2 (Homomorphism of graded module triangles).** Let \((P, >)\) be a poset and let \( G \) and \( G' \) be graded module triangles over \((P, >)\).

a) A homomorphism of graded module triangles \( \theta : G \rightarrow G' \) consists of homomorphisms of graded modules \( \theta(I) : G(I) \rightarrow G'(I), I \in \mathcal{I}(P, >) \), such that the following diagram
commutes for all \((I, J) \in \mathcal{J}_2(P, >)\):

\[
(1) \quad \begin{array}{c}
\cdots \rightarrow G(I) \xrightarrow{i} G(IJ) \xrightarrow{p} G(J) \xrightarrow{\partial} G(I) \rightarrow \cdots \\
\ \downarrow \theta(I) \quad \downarrow \theta(IJ) \quad \downarrow \theta(J) \quad \downarrow \theta(I)
\end{array}
\]

b) An isomorphism of graded module triangles \(\theta : G \rightarrow G'\) is a homomorphism of graded module triangles where all \(\theta(I)\) are isomorphisms of graded modules.

The two dimensional unraveling of the above diagram is:

\[
(2) \quad \begin{array}{c}
\cdots \rightarrow G(I) \xrightarrow{i} G(IJ) \xrightarrow{p} G(J) \xrightarrow{\partial} G(I) \rightarrow \cdots \\
\ \downarrow \theta(I) \quad \downarrow \theta(IJ) \quad \downarrow \theta(J) \quad \downarrow \theta(I)
\end{array}
\]

\[
\cdots \rightarrow G'(I) \xrightarrow{i'} G'(IJ) \xrightarrow{p'} G'(J) \xrightarrow{\partial'} G'(I) \rightarrow \cdots
\]

**Definition 2.3** (Chain complex triangle). Let \((P, >)\) be a poset. A chain complex triangular system or simply a chain complex triangle \(C\) over \((P, >)\) consists of chain complexes \(C(I), I \in \mathcal{J}(P, >)\), and chain maps \(i(I, IJ) : C(I) \rightarrow C(IJ)\) and \(p(IJ, J) : C(J) \rightarrow C(J)\) for all \((I, J) \in \mathcal{J}_2(P, >)\), satisfying the following two conditions:

a) The complex \(0 \rightarrow C(I) \xrightarrow{i(I, IJ)} C(IJ) \xrightarrow{p(IJ, J)} C(J) \rightarrow 0\) is quasi-isomorphic\(^1\) to a distinguished triangle of complexes.

b) If \(I, J \in \mathcal{J}(P, >)\) are noncomparable, then \(i(I, IJ)p(JI, I) = \text{id}_{C(I)}\).

Short exact and short weakly exact sequences are examples of complexes quasi-isomorphic to a distinguished triangle of complexes. A sequence \(0 \rightarrow C' \xrightarrow{i} C \xrightarrow{p} C'' \rightarrow 0\) of complexes is called short exact if \(i\) is injective, \(ip = 0\), and \(C/\text{im}(i) \cong C''\) induces isomorphism on homology. Using the cylinder-cone-translation construction \([GM03, \text{III.3}]\) one can construct distinguished triangles out of such sequences.

**Remark 2.4** (Chain complex generated triangles). Let \((P, >)\) be a poset and \(C\) a chain complex triangle over \((P, >)\). The homology modules \(H(I), I \in \mathcal{J}(P, >)\), together with the homomorphisms \(i(I, IJ) : H(I) \rightarrow H(IJ)\) and \(p(IJ, J) : H(IJ) \rightarrow H(J)\) induced by the chain maps \(i(I, IJ)\) and \(p(IJ, J)\) form a graded module triangle \(HC\) over \((P, >)\).

\(^1\)More precisely, isomorphic in the localized category, in which one inverts quasi-isomorphisms, where quasi-isomorphisms are chain maps inducing isomorphism on homology \([GM03, \text{III.2}]\).
2.3. C-Connection and connection matrices. We fix a poset \((P, >)\). In what follows, we consider collections \(C = \{C(p) \mid p \in P\}\) of graded modules, which are indexed by \(P\), and a homomorphism \(\Delta : \bigoplus_{p \in P} C(p) \rightarrow \bigoplus_{p \in P} C(p)\).

For an interval \(I\) in \((P, >)\) set \(C(I) := \bigoplus_{p \in I} C(p)\) and denote by \(\Delta(I)\) the homomorphism \(\iota_I \Delta \pi_I\), where \(\iota_I : C(I) \rightarrow C(P)\) is the canonical injection and \(\pi_I : C(P) \rightarrow C(I)\) is the canonical projection.

If \(p_1, p_2 \in P\), we refer to the restriction of \(\Delta\) to \(C(p_1)\) by \(\Delta_{p_1} : C(p_1) \rightarrow C(P)\), and the composition \(\Delta_{p_1} \pi_{p_2}\), where \(\pi_{p_2}\) is the projection \(C(P) \rightarrow C(p_2)\), is denoted by \(\Delta_{p_1, p_2} : C(p_1) \rightarrow C(p_2)\). Then \(\Delta\) can be visualized as a matrix with \(\Delta_{p_1}\) as its \(p_1\)-th row and \(\Delta_{p_1, p_2}\) as its entry at position \((p_1, p_2)\). The same applies to \(\Delta(I)\) for \(I \in \mathcal{I}(P, >)\), if \(p_1, p_2 \in I\).

**Definition 2.5** ([Fra89, Def. 1.3]). \(\Delta\) being as above:

a) \(\Delta\) is said to be lower triangular if \(\Delta_{p_1, p_2} \neq 0\) implies \(p_1 > p_2\) or \(p_1 = p_2\).

b) \(\Delta\) is said to be strictly lower triangular if \(\Delta_{p_1, p_2} \neq 0\) implies \(p_1 > p_2\).

c) \(\Delta\) is called a boundary map if each \(\Delta_{p_1, p_2}\) is a homomorphism of graded modules of degree \(-1\) and \(\Delta \circ \Delta = 0\).

**Proposition 2.6** ([Fra89, Prop. 3.3]). Let \(C = \{C(p) \mid p \in P\}\) be a collection of graded modules indexed by \(P\) and let \(\Delta : \bigoplus_{p \in P} C(p) \rightarrow \bigoplus_{p \in P} C(p)\) be a lower triangular boundary map. Then:

a) \(C(I)\) and \(\Delta(I)\) form a chain complex \(C^\Delta(I)\) for all \(I \in \mathcal{I}(P, >)\).

b) For all \((I, J) \in \mathcal{I}_2(P, >)\), the obvious injection and projection maps \(i(I, IJ)\) and \(p(IJ, J)\) are chain maps and

\[
0 \rightarrow C^\Delta(I) \xrightarrow{i(I, IJ)} C^\Delta(IJ) \xrightarrow{p(IJ, J)} C^\Delta(J) \rightarrow 0
\]

is a short exact sequence.

Using the above introduced notion the previous proposition simply asserts that \(C^\Delta\) is a chain complex triangle.

The following definition of a connection matrix avoids braids (cf. [Fra89, Def. 3.6]).

**Definition 2.7** ((C)-Connection matrix). Let \(G\) be a graded module triangle over \((P, >)\), \(C = \{C(p) \mid p \in P\}\) a collection of graded modules indexed by \(P\), and \(\Delta : \bigoplus_{p \in P} C(p) \rightarrow \bigoplus_{p \in P} C(p)\) a lower triangular boundary map. Let \(C^\Delta\) be the chain complex triangle formed by the \(C(I)\), \(\Delta(I)\), \(i(I, IJ)\), and \(p(IJ, J)\).

a) If \(HC^\Delta\) and \(G\) are isomorphic as graded module triangles, then \(\Delta\) is called a \(C\)-connection matrix for \(G\).

b) If furthermore \(C(p) \cong G(p)\), then \(\Delta\) is called a connection matrix for \(G\).

3. Octahedra and Braids and the Existence of \(C\)-Connection Matrices

In this section we want to review the necessary and sufficient conditions a graded module triangle \(G\) must satisfy so that a connection matrix (resp. \(C\)-connection matrix) for \(G\) exists.
3.1. Graded module octahedra.

**Definition 3.1** (Graded module octahedron). Let \((P, >)\) be a poset. A *graded module octahedral system* or simply a *graded module octahedron* \(G\) over \((P, >)\) is a graded module triangle over \((P, >)\) satisfying the extra condition:

c) For all \((I, J, K) \in \mathcal{I}_3(P, >)\) the following octahedron commutes and is distinguished:

![Diagram of octahedron](image)

By “commutes and is distinguished” the following is meant: First notice that there are two types of triangles resp. squares appearing in the octahedron: cyclic and noncyclic ones. For the cyclic ones (4 triangles and one square) we require distinguishedness and for the others (4 triangles and two squares) commutativity. Actually the distinguishedness of the square, which is the horizontal one, follows from the rest.

The two dimensional unraveling of the octahedron condition c) is the following braid condition \([\text{Fra88}, \text{Def. 1.1}]\):
c') For all \((I, J, K) \in \mathcal{I}_3(P, >)\) the following braid diagram commutes:

\[
\begin{align*}
G(I) & \xrightarrow{i} G(IJ) & \xrightarrow{p} G(J) \\
G(IJK) & \xrightarrow{p} G(JK) & \xrightarrow{i} G(J) \\
G(K) & \xrightarrow{p} G(J) & \xrightarrow{i} G(IJ) \\
G(J) & \xrightarrow{p} G(JK) & \xrightarrow{i} G(IJK)
\end{align*}
\]

**Remark 3.2.** It is worth noting that the octahedron appearing in the octahedral property c) of Definition 3.1 (which is equivalent to the braid property c') found by [Fra86] in the context of homology indices of index filtrations of Morse decompositions and exploited by him in [Fra88, Fra89] is the same as the “octahedron diagram” which is part of the definition of a triangulated category [GM03, IV.1, Axiom TR4].

**Definition 3.3** (Homomorphism of graded module octahedra). Let \((P, >)\) be a poset and let \(G\) and \(G'\) be graded module octahedra over \((P, >)\).

a) A **homomorphism of graded module octahedra** \(\theta : G \to G'\) is a homomorphism of the underlying graded module triangles.

b) An **isomorphism of graded module octahedra** \(\theta : G \to G'\) is a homomorphism of graded module octahedra where all \(\theta(I)\) are isomorphisms of graded modules.

This is equivalent to the definition of homomorphisms and isomorphisms of graded module braids appearing in [Fra88, Def. 1.2].

**Remark 3.4.** One notices that isomorphism of two graded module octahedra (resp. braids) amounts to the isomorphism of the underlying graded module triangles. Note that for each interval \(I\) there is exactly one isomorphism \(\theta(I) : G(I) \to G'(I)\) entering in all the commutative diagrams in (1) (or (2)). This condition will be essential in Subsection 3.3.

3.2. **Chain complex octahedra.**

**Definition 3.5** (Chain complex octahedron, [Fra89, Def. 2.6]). Let \((P, >)\) be a poset. A **chain complex octahedral system** or simply a **chain complex octahedron** \(C\) over \((P, >)\) is a chain complex triangle satisfying the extra condition:

\[c)\] For all \((I, J, K) \in \mathcal{I}_3(P, >)\) the following octahedron commutes and is distinguished:
Since, up to quasi-isomorphism, we are talking about distinguished triangles we can complete the missing edges of the above octahedron and obtain a full octahedron as in Definition 3.1, but now on the level of complexes (up to quasi-isomorphism). This explains again “commutes and is distinguished”.

The two dimensional unraveling of the above octahedron is called a chain complex braid:

Proposition 3.6 ([Fra89, Prop. 2.7]). Let $(P, >)$ be a poset and $C$ a chain complex octahedron (resp. braid) over $(P, >)$. The homology modules $H(I), I \in J(P, >)$, together with the homomorphisms $i(I, IJ) : H(I) \to H(IJ)$ and $\pi(IJ, J) : H(IJ) \to H(J)$ induced by the chain maps $i(I, IJ)$ and $p(IJ, J)$ form a graded module octahedron (resp. braid) $HC$ over $(P, >)$.

A graded module octahedron (resp. braid) $G$ which is defined as the homology of a chain complex octahedron (resp. braid) is said to be chain complex generated.

Proposition 3.7 ([Fra89, Prop. 3.4]). Let $(P, >)$ be a poset. Further let $\{C(p) \mid p \in P\}$ be a collection of graded modules indexed by $P$ and let $\Delta : \bigoplus_{p \in P} C(p) \to \bigoplus_{p \in P} C(p)$ be a lower triangular boundary map. Then the chain complexes $C^\Delta(I)$ defined by the $C(I)$ and $\Delta(I)$ together with the chain maps $i(I, IJ)$ and $p(IJ, J)$ form a chain complex octahedron (resp. braid).

In other words, for a $(C)$-connection matrix for the graded module triangle $G$ to exist, $G$ must be a graded module octahedron (resp. braid).
3.3. Octahedra and braids are obsolete in the definition of (C)-connection matrices. When we wanted to implement the definition of connection and C-connection matrices in the Maple package conley, we discovered that one can completely avoid introducing the notions of chain complex octahedra (resp. braids) and of graded module octahedra (resp. braids):
First notice that for $C^\Delta$ to form a chain complex braid, the matrix $\Delta$ must only satisfy the conditions of Proposition 3.7. By Proposition 3.6 $HC^\Delta$ is then a graded module braid. In other words, the only conditions on $\Delta$ for $HC^\Delta$ to be a graded module braid are those of Proposition 3.7:

a) $\Delta$ is lower triangular.
b) $\Delta$ is a boundary map.
Furthermore Remark 3.4 says that for testing the isomorphism of $HC^\Delta$ and $G$ one only needs the isomorphism of the underlying triangles, provided that:

(*) For each interval $I$ there is only one isomorphism $\theta(I) : HC^\Delta(I) \to G(I)$ entering in all the commutative diagrams in (1) (resp. (2)).

3.4. Franzosa’s existence results for C-connection matrices. Now that we have collected the necessary notions we can state the main existence result for C-connection matrices:

**Theorem 3.8** ([Fra89], Theorem 3.8). Let $G$ be a chain complex generated graded module octahedron, $C = \{C(p) \mid p \in P\}$ a collection of free graded modules and $\delta = \{\delta(p) : C(p) \to C(p) \mid p \in P\}$ a collection of boundary maps, such that the homology of $(C(p), \delta(p))$ coincides with $G(p)$. Then there exists a C-connection matrix $\Delta$ for $G$ with $\Delta_{p,p} = \delta(p)$.

The converse is established by Propositions 3.7 and 3.6.

**Corollary 3.9.** If $G$ is a chain complex generated graded module octahedron and $G(p)$ is free for all $p \in P$, then there exists a connection matrix $\Delta$ for $G$.

*Proof. Set $C(p) = G(p)$ with zero differential.*

4. Symmetric Connection Matrices

Let $(P, >)$ be a poset and $\Gamma$ be a subgroup of the automorphism group $\text{Aut}(P, >)$, i.e. $q > p$ implies $\sigma q > \sigma p$ for all $\sigma \in \Gamma$. The action of $\Gamma$ on $P$ induces an action on $\mathbb{J}_n(P, >)$ for all $n \in \mathbb{N}$.

Let $C = \{C(p) \mid p \in P\}$ be a collection of graded modules indexed by $P$. An action of $\Gamma$ on $C$ is given by specifying for each $\sigma \in \Gamma$ and each $p \in P$ an isomorphism, which we simply denote by $\psi(\sigma) : C(p) \to C(\sigma p)$, such that $\psi(\sigma \tau) = \psi(\sigma) \psi(\tau)$ for all $\sigma, \tau \in \Gamma$ and $\psi(\text{id}_P) = \text{id}$.  

2A nice coincidence.
We say a linear map $\Delta : \bigoplus_{p \in P} C(p) \to \bigoplus_{p \in P} C(p)$ is $\Gamma$-symmetric, if for all $p, q \in P$ and $\sigma \in \Gamma$ the following diagram commutes:

\[
\begin{array}{ccc}
C(q) & \xrightarrow{\Delta_{q,p}} & C(p) \\
\psi(\sigma) \downarrow & & \psi(\sigma) \\
C(\sigma q) & \xrightarrow{\Delta_{\sigma q,\sigma p}} & C(\sigma p)
\end{array}
\]

Let $C$ be a chain complex triangle. An action of $\Gamma$ on $C$ is given by specifying for each $\sigma \in \Gamma$ and each $I \in \mathcal{J}(P, >)$ an isomorphism, which we simply denote by $\psi(\sigma) : C(I) \to C(\sigma I)$, such that

a) $\psi(\sigma\tau) = \psi(\sigma)\psi(\tau)$ for all $\sigma, \tau \in \Gamma$ and $\psi(\id_P) = \id$.

b) For all $I \in \mathcal{J}(P, >)$ and all $\sigma \in \Gamma$ the following diagram commutes:

\[
\begin{array}{ccc}
C(I) & \xrightarrow{\partial(I)} & C(I) \\
\psi(\sigma) \downarrow & & \psi(\sigma) \\
C(\sigma I) & \xrightarrow{\partial(\sigma I)} & C(\sigma I)
\end{array}
\]

c) For all $(I, J) \in \mathcal{J}_2(P, >)$ and all $\sigma \in \Gamma$ the following two diagrams commute:

\[
\begin{array}{ccc}
C(I) & \xrightarrow{i(I,J)} & C(IJ) \\
\psi(\sigma) \downarrow & & \psi(\sigma) \\
C(\sigma I) & \xrightarrow{i(\sigma I,\sigma J)} & C(\sigma IJ)
\end{array}
\hspace{1cm}
\begin{array}{ccc}
C(IJ) & \xrightarrow{p(I,J)} & C(J) \\
\psi(\sigma) \downarrow & & \psi(\sigma) \\
C(\sigma IJ) & \xrightarrow{p(\sigma IJ,\sigma J)} & C(\sigma J)
\end{array}
\]

Let $G$ be a graded module triangle. An action of $\Gamma$ on $G$ is given by specifying for each $\sigma \in \Gamma$ and each $I \in \mathcal{J}(P, >)$ an isomorphism, which we simply denote by $\psi(\sigma) : G(I) \to G(\sigma I)$, such that

a) $\psi(\sigma\tau) = \psi(\sigma)\psi(\tau)$ for all $\sigma, \tau \in \Gamma$ and $\psi(\id_P) = \id$.

b) For all $(I, J) \in \mathcal{J}_2(P, >)$ and all $\sigma \in \Gamma$ the following three diagrams commute:

\[
\begin{array}{ccc}
G(I) & \xrightarrow{i(I,J)} & G(IJ) \\
\psi(\sigma) \downarrow & & \psi(\sigma) \\
G(\sigma I) & \xrightarrow{i(\sigma I,\sigma J)} & G(\sigma IJ)
\end{array}
\hspace{1cm}
\begin{array}{ccc}
G(IJ) & \xrightarrow{p(I,J)} & G(J) \\
\psi(\sigma) \downarrow & & \psi(\sigma) \\
G(\sigma IJ) & \xrightarrow{p(\sigma IJ,\sigma J)} & G(\sigma J)
\end{array}
\hspace{1cm}
\begin{array}{ccc}
G(J) & \xrightarrow{\partial(J)} & G(I) \\
\psi(\sigma) \downarrow & & \psi(\sigma) \\
G(\sigma J) & \xrightarrow{\partial(\sigma J,\sigma I)} & G(\sigma I)
\end{array}
\]

Note that the existence of an action of non-trivial $\Gamma \leq \text{Aut}(P, >)$ is a non-trivial condition on $C$, resp. $G$.

**Remark 4.1** (Symmetric $C$-connection matrices). Let $\Gamma$ as above act on a collection $C = \{C(p) \mid p \in P\}$ of graded modules and let $\Delta : \bigoplus_{p \in P} C(p) \to \bigoplus_{p \in P} C(p)$ be a $\Gamma$-symmetric lower triangular boundary map. Then $\Gamma$ acts on $C^\Delta$ via $\psi(\sigma) : C(I) \to C(\sigma I)$ given by the direct sum of the $\psi(\sigma) : C(p) \to C(\sigma p)$, for all $p \in I$. It further acts on $HC^\Delta$ in an obvious way. Hence, for such a $\Gamma$-symmetric $\Delta$ to be a $C$-connection matrix of a graded module octahedron $G$, $\Gamma$ must act on $G$. 
More generally, if $\Gamma$ acts on a chain complex octahedron, it acts automatically on its homology graded module octahedron.

5. C-Connection Matrices of a Morse Decomposition

An inexhaustible reservoir of chain complex generated graded module octahedra are the homology graded module octahedra of a Morse decomposition of a dynamical system. This was proved in $[Fra86]$. See also $[Fra88, Fra89, Mis95, MM02]$ for further details, results and applications.

Let $X$ be a locally compact metric space. The object of study is a flow $\varphi : \mathbb{R} \times X \to X$, i.e. a continuous map $\mathbb{R} \times X \to X$ which satisfies $\varphi(0, x) = x$ and $\varphi(s, \varphi(t, x)) = \varphi(s + t, x)$ for all $x \in X$ and $s, t \in \mathbb{R}$.

For a subset $Y \subset X$ define

$$\text{Inv}(Y) := \text{Inv}(Y, \varphi) := \{x \in Y \mid \varphi(\mathbb{R}, x) \subset Y\} \subset Y,$$

the invariant subset of $Y$.

5.1. Homology Conley index. A subset $S \subset X$ is invariant under the flow $\varphi$, if $S = \text{Inv}(S)$. It is an isolated invariant set if there exists a compact set $Y \subset X$ (an isolating neighborhood) such that

$$S = \text{Inv}(Y) \subset Y^\circ,$$

where $Y^\circ$ denotes the interior of $Y$.

Let $M$ be an isolated invariant set $[Con78]$. A pair of compact sets $(N, L)$ with $L \subset N$ is called an index pair for $M$ if

a) $N \setminus L$ is an isolating neighborhood of $M$.

b) $L$ is positively invariant, i.e. $\varphi([0, t], x) \subset L$ for all $x \in L$ satisfying $\varphi([0, t], x) \subset N$.

c) $L$ is an exit set for $N$, i.e. for all $x \in N$ and all $t_1 > 0$ such that $\varphi(t_1, x) \not\in N$, there exists a $t_0 \in [0, t_1]$ for which $\varphi([0, t_0], x) \subset N$ and $\varphi(t_0, x) \in L$.

Every isolated invariant set $M$ has an index pair $(N, L)$ and the homology Conley index of $M$ is defined by

$$CH(M) := H(N, L).$$

$CH(M)$ is as such a graded module.

5.2. Morse decomposition. For a subset $Y \subset X$ the $\omega$-limit set of $Y$ is

$$\omega(Y) := \bigcap_{t > 0} \varphi([t, \infty), Y),$$

while the $\alpha$-limit set of $Y$ is

$$\alpha(Y) := \bigcap_{t > 0} \varphi((-\infty, -t), Y).$$

For two subsets $Y_1, Y_2 \subset X$ define the set of connecting orbits

$$\text{Con}(Y_1, Y_2) := \{x \in X \mid \alpha(x) \subset Y_1 \text{ and } \omega(x) \subset Y_2\}.$$
Let $S$ be an isolated invariant set and $(P, \succ)$ be a poset. A finite collection
\[ M(S) = \{ M(p) \mid p \in P \} \]
of disjoint isolated invariant subsets of $S$ is called a Morse decomposition if there exists
a strict partial order $\succ$ on $P$, such that for every $x \in S \setminus \bigcup_{p \in P} M(p)$ there exists $p, q \in P,$
such that $q \succ p$ and $x \in \text{Con}(M(q), M(p))$.

The sets $M(p)$ are called Morse sets. A partial order on $P$ satisfying this property is
said to be admissible.

There is a partial order $\succ_{\varphi}$ induced by the flow, generated by the relations $q \succ_{\varphi} p$
whenever $\text{Con}(M(q), M(p)) \neq \emptyset$. This so called flow-induced order is a subset of every
admissible order, and in this sense minimal. Normally this order is not known and one
is content with a coarser order. If, for example, an (energy) function $E$ is known with
$E(x) > E(\varphi(t, x))$ for all $t > 0$, then defining the partial order $\succ_E$ by
\[ q \succ_E p, \text{ iff } E(y) > E(x) \text{ for all } y \in M(q) \text{ and } x \in M(p), \]
yields an admissible order.

For an interval $I$ define the Morse set
\[ M(I) := \bigcup_{p \in I} M(p) \cup \bigcup_{p, q \in I} \text{Con}(M(q), M(p)). \]
$M(I)$ is again an isolated invariant set. If $(I, J) \in \mathcal{J}_2(P, \succ)$, then $(M(I), M(J))$ is an
attractor-repeller pair in $M(IJ)$.

**Remark 5.1.** In dynamical system theory Franzosa discovered in \cite{Fra86} a natural chain
complex octahedron, the so called chain complex octahedron $C^N$ defined by a so called index
filtration $N$ of a Morse decomposition. Its homology $H^N_C$ is by Proposition\ 3.6 a (chain
complex generated) graded module octahedron:

\[
\begin{array}{c}
\begin{array}{cccccc}
& & & & & 0 \\
& & & & & 0 \\
& & i_1 & & i_2 & 0 \\
& i_3 & & i_4 & & 0 \\
\end{array}
\begin{array}{cccccc}
0 & & C^N(I, \emptyset) & & 0 & \rightarrow \\
C^N(IJ, \emptyset) & & 0 & & C^N(I, \emptyset) & \\
C^N(IJK, \emptyset) & & 0 & & C^N(J, I) & \\
C^N(K, IJ) & & 0 & & 0 & \\
0 & & 0 & & 0 & \\
\end{array}
\end{array}
\]

where $C^N(A, B) := C(N(QAB), N(QB))$ for $A, B$ one of the above pairs of intervals and
$Q$ is a certain interval defined by $(I, J, K) \in \mathcal{J}_3(P, \succ)$. For the reasons mentioned in
Remark\ 5.1 below we won’t go into the details of this construction. The only thing one
has to know is that $C(N(QAB), N(QB))$ is the relative singular (or simplicial, ...) chain complex of the pair of compact topological spaces $(N(QAB), N(QB))$, which is an index pair for the MORSE set $M(A)$ (independent of $B$ and $Q$!), i.e. its relative homology being the homological CONLEY index $CH(M(A))$ of $M(A)$.

Definition 5.2 ($(C)$-Connection matrix of a MORSE decomposition). Given a MORSE decomposition with an index filtration $N$. A $(C)$-connection matrix of the MORSE decomposition is a $(C)$-connection matrix of $HC^N$. One can show that the definition is independent of the index filtration.

At this point we want to emphasize that in order to comply with Definition 2.7, one needs to correctly identify the $CH(M(A))$ arising as the homology of the different, but quasi-isomorphic complexes coming from the topological setup.

Remark 5.1 states that $G = HC^N$ is automatically a chain complex generated graded module octahedron. In other words, in the context of $(C)$-connection matrices of MORSE decompositions, one never needs to check the octahedron (resp. braid) condition. Cf. [Fra86, p. 574, below Theorem 3.8].

It remains to mention why the theory of $(C)$-connection matrices is relevant in the context of MORSE decompositions. There is a link between existence of connecting orbits and non-triviality of entries of connection matrices. For details see for example [MM02, 4.1.1].

6. The Maple Package conley

Although the theory of $C$-connection matrices is a purely algebraic theory, we’ve chosen conley as the name of our Maple package in honor of CHARLES CONLEY, since his index theory [Con78] is a natural field for applying these ideas. As mentioned above, the case $G = HC^N$ is of special interest to applications.

In CONLEY index theory one uses as much topological data as possible given by (the index filtration of) the MORSE decomposition to restrict the possible connection matrices $\Delta$ for $HC^N$.

Remark 6.1 (Even less is used in practice). Typically, the only data that are given are the isomorphism types of the homology CONLEY indices $CH(M(I))$ for some $I \in I(P, >)$. Nevertheless, the minimal data required remains the isomorphism type of the homology CONLEY indices for all one element intervals.

As mentioned at the end of Remark 5.1, one needs, in order to apply the definition of a connection matrix, to identify for each interval $I$ the homologies of different index pairs for $M(I)$ inside the index filtration, which are all isomorphic to $CH(M(I))$. Since this is an extremely demanding task, and up to our knowledge not addressed yet, one cannot make use of condition $(*)$.

\footnote{In talking about the chain complex braid we use the fact that the quasi-isomorphism type of $C^N(A, B)$ neither depends on $B$ nor on $Q$.}
To be able to make use of the commutativity of the squares in (1) (resp. (2)) one needs the induced maps coming from the index triples for each pair of adjacent intervals, a data which is rarely provided.

Summing up, in the majority of non-trivial examples, the data of the index filtration for the Morse decomposition are up to our knowledge not known completely. In particular one can neither make use of condition (∗) nor even of the commutativity of the squares in (1) (resp. (2)) to impose further restrictions on ∆. The only restriction left on ∆ is the abstract isomorphism between $HC^\Delta(I)$ and $CH(M(I))$, in case the isomorphism type of the latter is known. Due to this lack of topological data the package conley only imposes the last mentioned restriction on ∆. If at some point in the future such data are provided, conley can easily be extended to make use of them.

7. Examples

In each of the four examples in this section the set of all connection matrices which are compatible with the given data of the flow under consideration are computed using the Maple package conley. As conley is based on homalg, the computations on the level of homological algebra are carried out by homalg. Since in the following examples we compute with modules over a principal ideal ring, the so-called ring package PIR is used to do the ring arithmetics for homalg [BR].

For the conley package the following conventions to provide graded modules, e.g. homology modules, are used:

- The most elaborate notation is to provide the graded components as list of presentations in the homalg format.
- If all graded components are free modules then a list of ranks suffices.
- If the graded module is of rank 1 and concentrated in one degree then this degree is sufficient as input. In this case, we call this degree the index of the graded module.

7.1. A flow with $V_4 \times C_2 \cong C_3^3$-symmetry. We consider a $C_3^3$-symmetric flow on the 2-sphere with six hyperbolic equilibria. They are enumerated as shown in the following figure:

> restart;
> with(conley): with(PIR): with(homalg):
> 'homalg/default' := 'PIR/homalg':
> We want to compute over $\mathbb{Z}/2\mathbb{Z}$:
> var := [2];
The set $P$ of six equilibria of the flow is defined:

\[
P := [0, 1, 2, 3, 4, 5]
\]

The symmetry group $\Gamma := V_4 \times C_2 \cong C_2^3$ is generated by the following permutations:

\[
V4C2 := [[[1, 3]], [[2, 4]], [[0, 5]]];
\]

The generating set of relations for $\Gamma$ is given by:

\[
rel := [[1, 0], [0, 2]];
\]

The $\Gamma$-symmetry gives more relations:

\[
\text{Orbits}(V4C2, rel);
\]

\[
\text{rel} := [1, 0, 1, 2, 0, 2, 0, 1];
\]

The $\Gamma$-orbits on the six equilibria of the flow is defined:

\[
\text{CH} := [1, 2, 0, 2, 0, 1];
\]

The homology of the sphere is added as homology $\text{CONLEY}$ index of $M(P)$:
The following computation of all connection matrices takes into account the \( \Gamma \)-symmetry. The optional string "full notation" means that for the matrix \( \Delta_i : \bigoplus_{p \in P} CH_i(p) \to \bigoplus_{p \in P} CH_{i-1}(p) \) a zero row is reserved for every trivial \( CH_i(p) \) and a zero column is reserved for every trivial \( CH_{i-1}(p) \). In the hyperbolic case this leads to \( |P| \times |P| \)-square matrices:

\[
\text{Con} := \begin{bmatrix}
0 & 1 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 1
\end{bmatrix},
\begin{bmatrix}
0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 0
\end{bmatrix},
\begin{bmatrix}
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 1
\end{bmatrix},
\begin{bmatrix}
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 1
\end{bmatrix}
\]

We conclude that there is exactly one connection matrix which is compatible with the given data. It is given by the list containing the matrices which represent the boundary maps from \( \bigoplus_{p \in P} CH_i(p) \) to \( \bigoplus_{p \in P} CH_0(p) \) resp. from \( \bigoplus_{p \in P} CH_2(p) \) to \( \bigoplus_{p \in P} CH_1(p) \). Finally, we check that connecting orbits from 1 to 0 resp. from 0 to 2 exist:

\[
\text{map} (\text{ConnectionSubmatrix}, \text{Con}, P, [1,0], CHp, var);
\]

\[
\begin{bmatrix}
0 \\
1
\end{bmatrix}
\]

\[
\text{map} (\text{ConnectionSubmatrix}, \text{Con}, P, [0,2], CHp, var);
\]

\[
\begin{bmatrix}
1 \\
0
\end{bmatrix}
\]

Since the format of the connection matrices may change in the future, the user is recommended to use the above way of accessing the entries of the connection matrices.

7.2. A flow with \( D_6 \times C_2 \cong D_{12} \)-symmetry. Here we use conley to compute the connection matrices of a \( D_{12} \)-symmetric flow on the 2-sphere with six hyperbolic and two non-hyperbolic equilibria. They are enumerated as shown in the following figure:

The following two figures give a simple view of the upper resp. lower hemisphere:
Around 0 resp. 7 an isolating neighborhood looks like:

\[(N_i, L_i)\] is an index pair for \(i = 0, 7\), where \(L_i\) is the disjoint union of the three bold border regions of the isolating neighborhood \(N_i\) of \(i\). The index pair \((N_i, L_i)\) is homotopy equivalent to the simplicial complex:

```maple
> restart;
> with(conley): with(PIR): with(homalg):
> 'homalg/default' := 'PIR/homalg':
We set up the field of coefficients to be \(\mathbb{F}_2 := \mathbb{Z}/2\mathbb{Z}\):
> var := [2];

\[\text{var} := [2]\]
> Pvar(var);

\[\text{"Z/pZ", 2}\]
We define the set \(P\) of equilibria and the generators for \(\Gamma := D_{12}\):
> P := [0, 1, 2, 3, 4, 5, 6, 7];

\[P := [0, 1, 2, 3, 4, 5, 6, 7]\]
> D6C2 := [[[1, 3, 5], [2, 4, 6]], [[3, 5], [2, 6]], [[0, 7]]];

\[D6C2 := [[[1, 3, 5], [2, 4, 6]], [[3, 5], [2, 6]], [[0, 7]]]\]
The action of the generating permutations \((1, 3, 5)(2, 4, 6), (3, 5)(2, 6)\) and \((0, 7)\) on \(\bigoplus_{p \in P} CH_i(p)\) for \(i = 0, 1, 2\) is represented by the following matrices. More precisely, for each generator we give an equation whose left hand side is the permutation \(\pi\) of the set \(P\) and whose right hand side is the corresponding list \([M_0(\pi), M_1(\pi), M_2(\pi)]\) of matrices representing the action of \(\pi\) on the respective \(\bigoplus_{p \in P} CH_i(p), i = 0, 1, 2\). The dimensions of
```
the matrices are coherent with the so called standard notation ("std notation") explained below:

\[ \text{id} := \text{linalg[diag]}(1\$3); \]
\[ \text{rho} := \text{matrix}([[0, 1, 0], [0, 0, 1], [1, 0, 0]]); \]
\[ \text{rep} := [\text{rho}, \text{matrix}([[0, 1, 0], [1, 0, 0], [0, 0, 1], [0, 0, 1, 1]]), \text{rho}], \]
\[ \text{matrix}([[0, 0, 1], [0, 1, 0], [1, 0, 0]]), \text{matrix}([[1, 1, 0, 0], [0, 1, 0, 0], [0, 0, 1, 1], [0, 0, 0, 1]]), \text{matrix}([[1, 0, 0], [0, 0, 1, 1], [0, 1, 0], [0, 0, 1]]), \text{matrix}([[0, 0, 1], [0, 1, 0], [1, 0, 0]]), \text{id}]; \]
\[ \text{id} := \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \]
\[ \rho := \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix} \]

\[ \text{D6C2_rep} := \text{zip}((a, b) -> a = b, \text{D6C2}, \text{rep}); \]

\[ \text{D6C2_rep} := \text{matrix}([[[1, 3, 5], [2, 4, 6]] = \left[ \begin{array}{c} 0 & 1 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 \end{array} \right], \rho], \right) \]

\[ \text{[3, 5], [2, 6]} = \left[ \begin{array}{c} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{array} \right], \left[ \begin{array}{c} 1 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 \end{array} \right], \left[ \begin{array}{c} 0 & 0 & 1 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{array} \right], \right) \]

\[ \text{[0, 7]} = \text{id}, \left[ \begin{array}{c} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{array} \right], \text{id} \]

A simple calculation shows that

\[ \text{CH}_1(0) := H_1(N_0, L_0) \cong \mathbb{F}_2 a \oplus \mathbb{F}_2 b \oplus \mathbb{F}_2 c / \mathbb{F}_2(a + b + c) = \langle \overline{a}, \overline{b}, \overline{c} \rangle \cong \mathbb{F}_2^{1 \times 2} \]

resp.

\[ \text{CH}_1(7) := H_1(N_7, L_7) \cong \mathbb{F}_2 d \oplus \mathbb{F}_2 e \oplus \mathbb{F}_2 f / \mathbb{F}_2(d + e + f) = \langle \overline{d}, \overline{e}, \overline{f} \rangle \cong \mathbb{F}_2^{1 \times 2} \]

The \( \mathbb{F}_2 \)-basis of \( \bigoplus_{p \in P} \text{CH}_1(p) = \text{CH}_1(0) \oplus \text{CH}_1(7) \) is \( \mathbb{F}_2^{1 \times 2} \oplus \mathbb{F}_2^{1 \times 2} \cong \mathbb{F}_2^{1 \times 4} \) which was chosen to write down the above matrices is \( \langle \overline{a}, \overline{b}, \overline{d}, \overline{e} \rangle \).

Next we define the generating set of relations for >:

\[ \text{rel} := [[1, 0], [0, 2]] ; \]

\[ \text{rel} := [[1, 0], [0, 2]] \]

The orbits of these relations under the given symmetry group are obtained as follows:
Next we provide the homology indices. Note that since 0 and 7 are non-hyperbolic, their homology is not of rank 1.

\begin{verbatim}
> Chp := [[0, 2], 2, 0, 2, 0, 2, 0, [0, 2]];

CHp := [[0, 2], 2, 0, 2, 0, 2, 0, [0, 2]]
\end{verbatim}
For the given homology Conley indices respecting the symmetry group $Γ$ generated by $D_6C_2$, where the action of $Γ$ on $\bigoplus_{p \in P} CH_i(p)$ for $i = 0, 1, 2$ by the matrices defined above is taken into account. The optional string "std notation" means that the matrix $Δ_i : \bigoplus_{p \in P} CH_i(p) \to \bigoplus_{p \in P} CH_{i-1}(p)$ is a $d_i \times d_{i-1}$-matrix, where $d_j := \dim_{F_2} \bigoplus_{p \in P} CH_j(p)$.

We conclude that there is exactly one connection matrix which is compatible with the given data. It is given by the list containing the matrices which represent the boundary maps from $\bigoplus_{p \in P} CH_1(p)$ to $\bigoplus_{p \in P} CH_0(p)$ resp. from $\bigoplus_{p \in P} CH_2(p)$ to $\bigoplus_{p \in P} CH_1(p)$. Here we extract the information about connecting orbits between points in $P$ which is provided by the computed connection matrix:

Hence, there are connecting orbits from 0 to 2, to 4, to 6, and from 7 to 2, to 4, and to 6.

```plaintext
> Con:=ConnectionMatrices(P,rel,CH,var,"Symmetry"=D6C2_rep,"std_notatio n";

Con := 
\[
\begin{bmatrix}
    0 & 1 & 1 \\
    1 & 0 & 1 \\
    0 & 1 & 1 \\
    1 & 0 & 1
\end{bmatrix},
\begin{bmatrix}
    0 & 1 & 0 & 1 \\
    1 & 1 & 1 & 1 \\
    1 & 0 & 1 & 0
\end{bmatrix}
\]

> ConnectionSubmatrix(Con[1],P,[0,2],CHp,var),
> ConnectionSubmatrix(Con[1],P,[0,4],CHp,var),
> ConnectionSubmatrix(Con[1],P,[0,6],CHp,var);
> ConnectionSubmatrix(Con[1],P,[7,2],CHp,var),

    1 & 0
\end{bmatrix},
\begin{bmatrix}
    1 & 0
\end{bmatrix}
\]

> ConnectionSubmatrix(Con[1],P,[1,0],CHp,var),
> ConnectionSubmatrix(Con[1],P,[1,7],CHp,var);
> ConnectionSubmatrix(Con[1],P,[3,0],CHp,var),
> ConnectionSubmatrix(Con[1],P,[3,7],CHp,var);
> ConnectionSubmatrix(Con[1],P,[5,0],CHp,var),
> ConnectionSubmatrix(Con[1],P,[5,7],CHp,var);
```

```plaintext
\[
\begin{bmatrix}
    0 \\
    1
\end{bmatrix},
\begin{bmatrix}
    0 & 1
\end{bmatrix},
\begin{bmatrix}
    1 & 0
\end{bmatrix}
\]

> ConnectionSubmatrix(Con[1],P,[1,0],CHp,var),
> ConnectionSubmatrix(Con[1],P,[1,7],CHp,var);
> ConnectionSubmatrix(Con[1],P,[3,0],CHp,var),
> ConnectionSubmatrix(Con[1],P,[3,7],CHp,var);
> ConnectionSubmatrix(Con[1],P,[5,0],CHp,var),
> ConnectionSubmatrix(Con[1],P,[5,7],CHp,var);
```

```plaintext
\[
\begin{bmatrix}
    0 & 1 \\
    1 & 0
\end{bmatrix},
\begin{bmatrix}
    1 & 1
\end{bmatrix}
\]

> ConnectionSubmatrix(Con[1],P,[1,0],CHp,var),
> ConnectionSubmatrix(Con[1],P,[1,7],CHp,var);
> ConnectionSubmatrix(Con[1],P,[3,0],CHp,var),
> ConnectionSubmatrix(Con[1],P,[3,7],CHp,var);
> ConnectionSubmatrix(Con[1],P,[5,0],CHp,var),
> ConnectionSubmatrix(Con[1],P,[5,7],CHp,var);
```

```plaintext
\[
\begin{bmatrix}
    0 \\
    1
\end{bmatrix},
\begin{bmatrix}
    0 & 1
\end{bmatrix},
\begin{bmatrix}
    1 & 0
\end{bmatrix}
\]
```
Similarly, there are connecting orbits from 1 to 0 and 7, from 3 to 0 and 7, and from 5 to 0 and 7.

7.3. The Cahn-Hilliard equation. In this example we consider a $D_8$-symmetric flow with nine hyperbolic equilibria studied in [MPMW, 2.2, 4.2]. We stick to the notation of the equilibria of that reference:

\[
\text{restart;}
\]
\[
\text{with(conley): with(PIR): with(homalg):}
\]
\[
\text{‘homalg/default’:=’PIR/homalg‘:}
\]
\[
\text{var:=[2];}
\]
\[
\text{Pvar(var);}
\]
\[
\text{[“Z/pZ”, 2]}
\]
\[
\text{P:=[x0, x1, x2, x3, d0, d1, d2, d3, m];}
\]
\[
\text{P := [x0, x1, x2, x3, d0, d1, d2, d3, m]}
\]
\[
\text{CHp:=[0,0,0,0,1,1,1,1,2];}
\]
\[
\text{CHp := [0, 0, 0, 0, 1, 1, 1, 1, 2]}
\]
\[
\text{rel:=DefinePartialOrderByPotential(P,CHp,P);} 
\]
\[
\text{rel := [[d0, x0], [d1, x0], [d2, x0], [d3, x0], [m, x0], [d0, x1], [d1, x1], [d2, x1], [d3, x1], [m, x1], [d0, x2], [d1, x2], [d2, x2], [d3, x2], [m, x2], [d0, x3], [d1, x3], [d2, x3], [d3, x3], [m, x3], [m, d0], [m, d1], [m, d2], [m, d3]]}
\]
\[
\text{ord:=GeneratePartialOrder(P,rel);} 
\]
\[

\]

We obtain two connection matrices. The full flow diagram above would give a unique \( D_3 \) symmetric connection matrix, but this diagram was derived in [MPMW] using dynamical arguments. Here we demonstrated that the lack of the dynamical arguments produces ambiguities. This is the point of departure in a joint work in progress with MAIER-PAAPE.

### 7.4. An example for a \( C \)-connection matrix.

Here we demonstrate on a tiny example the advantage of a \( C \)-connection matrix over a connection matrix. The aim is to look at the two equilibria 0 and 1 of the flow visualized in

\[ \begin{array}{c}
\bullet & \bullet & \bullet \\
0 & 1 & 2
\end{array} \]

as a black box. Then the flow can also be depicted as follows:

\[ \begin{array}{c}
\bullet & \bullet \\
1 & 2
\end{array} \]

Here we named the black box equilibrium again by 1.

> restart;
> with(conley): with(PIR): with(homalg):
> 'homalg/default' := 'PIR/homalg':
> We set up the field of coefficients to be \( \mathbb{F}_2 := \mathbb{Z}/2\mathbb{Z} \):
> var:=[2];
var := [2]

> Pvar(var);
> P := [0, 1, 2];

The potential values/or the indices:

> CHp := [1, 0, 1];

> rel := [[0, 1], [2, 1]];

> ord := GeneratePartialOrder(P, rel);

> I1 := GenerateIntervals(P, rel);

> #I123 := GenerateAdjacentIntervals(P, rel);

> CH := [op(zip((x, y) -> x = y, P, CHp)), [0, 1] = [], [1, 2] = [], P = 1];

> Con := ConnectionMatrices(P, rel, CH, var, "full_notation");

Now we consider [0, 1] as one point which we call 1:

> Q := [1, 2];

This means, we take \( C(1) := C_0(1) \oplus C_1(1) = \mathbb{F}_2 \oplus \mathbb{F}_2 \) and \( C(2) := C_0(2) \oplus C_1(2) = 0 \oplus \mathbb{F}_2 \):

> Cp := [1 = [1, 1], 2 = 1];

> Crel := [[2, 1]];

The homology CONLEY index of the black box 1 is \( CH(1) = 0 \):

> CCH := [1 = [], Q = 1];

The procedure CConnectionMatrices reads off the missing CONLEY indices from its third argument Cp, so the complete data will be \( CH(1) = 0, CH(2) = CH_0(2) \oplus CH_1(2) = 0 \oplus \mathbb{F}_2 \) and \( CH([1, 2]) = CH_0([1, 2]) \oplus CH_1([1, 2]) = 0 \oplus \mathbb{F}_2 \):

> CCon := CConnectionMatrices(Q, Crel, Cp, CCH, var, "full_notation");
\[ C_{Con} := \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} 1 & 0 \\ 1 & 0 \end{bmatrix} \]

Since \( C(0) \) was chosen to be different from \( CH(0) \) the corresponding diagonal entry of the \( C \)-connection matrix does not vanish:

\[ \map{\text{ConnectionSubmatrix}}{C_{Con}}{Q}{[1,1]}{\map{\text{rhs}}{Cp}}{\text{var}}; \]
\[ \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \begin{bmatrix} 1 \\ 0 \end{bmatrix} \]

\[ \map{\text{ConnectionSubmatrix}}{C_{Con}}{Q}{[2,2]}{\map{\text{rhs}}{Cp}}{\text{var}}; \]
\[ \begin{bmatrix} 0 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 0 \end{bmatrix} \]

\[ \map{\text{ConnectionSubmatrix}}{C_{Con}}{Q}{[1,2]}{\map{\text{rhs}}{Cp}}{\text{var}}; \]
\[ \begin{bmatrix} 0 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 0 \end{bmatrix} \]

For the specified data there exist two compatible \( C \)-connection matrices. The second connection matrix would imply a connecting orbit from 2 to 1:

\[ \map{\text{ConnectionSubmatrix}}{C_{Con}}{Q}{[2,1]}{\map{\text{rhs}}{Cp}}{\text{var}}; \]
\[ \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \end{bmatrix} \]

In particular, computations with \( C \)-connection matrices allow one to consider Morse decompositions with Morse sets having trivial homology Conley indices, i.e. with \( CH(p) = 0 \).

8. Conclusion

We noticed during the implementation that the braid condition usually appearing in the definition of \( (C) \)-connection matrices is, due to Franzosa’s result in Prop. 3.7, automatically satisfied and does not impose any further restrictions on the matrices. This led us to the simplified Definition 2.7. We adapted the classical definitions to the modern language of derived categories and introduced triangles and octahedra. Since sufficiently many of the examples studied in dynamical systems are symmetric, we gave a precise definition of a symmetric \( C \)-connection matrix and studied an example with non-hyperbolic equilibria, where the symmetry group acts non-trivially on the homology Conley indices of the non-hyperbolic equilibria.

The purpose of the package conley [BR07] is to automatize long computations and free the user from lots of technical details, by this allowing him to deal with large (generic) examples, which can hardly be processed by hand. We hope that the package eliminates some of the difficulties one might encounter while entering this, in our opinion, very interesting area of dynamical systems.

Larger and more interesting examples than in Section 7 will be studied in future joint work with Maier-Paape. There conley’s ability to compute transition matrices will be another essential ingredient.
