Abstract

Background

Sepsis is a common complication of severe wound injury and infection, with a very high mortality rate. The P2Y12 receptor inhibitor, cangrelor, is an antagonist antiplatelet drug.

Methods

In our study, we investigated the protective mechanisms of cangrelor in CLP-induced pulmonary injury in sepsis, using mouse models.

Results

TdT-mediated dUTP Nick-End Labeling (TUNEL) and Masson staining showed that apoptosis and fibrosis in lungs were alleviated by cangrelor treatment. Cangrelor significantly promoted surface expression of CD40L on platelets and inhibited CLP-induced neutrophils in Bronchoalveolar lavage fluid (BALF). We also found that cangrelor decreased the inflammatory response in the CLP mouse model and inhibited the expression of inflammatory cytokines, IL-1β, IL-6, and TNF-α. Western blotting and RT-PCR showed that cangrelor inhibited the increased levels of G-protein-coupled receptor 17 (GPR17) induced by CLP.

Conclusion: Our study indicated that cangrelor repressed the levels of GPR17, followed by a decrease in the inflammatory response and a rise of neutrophils in BALF, potentially reversing CLP-mediated pulmonary injury during sepsis.

Background

Sepsis is a serious disease and will lead a high death rate in all over the world. It has several features like out of controlled inflammatory response, Coagulation disorder, and immune dysfunctions[1]. The cause of sepsis is complex, and its main cause is a response caused by the host's immune response to the pathogen [1, 2]. Overall, the physiological and pathological mechanisms of sepsis are well-researched. A lot of mediators like cytokines, chemokines, and free radicals participate in the development of sepsis [3]. The lung is the initial target organ of the systemic inflammatory response caused by sepsis, leading to alveolar or capillary epithelial cell injury, diffuse pulmonary interstitial edema, and inflammatory cell exudation (i.e., acute lung injury/respiratory distress syndrome, progressive respiratory distress, and hypoxemia) [4, 5]. Despite numerous treatment strategies, drugs that effectively improve the treatment of sepsis remain to be developed. Antibiotics are the key method for clinical treatment, but the death rate of sepsis still reaches an astonishing number of 30%~40% [6].

In the past few years, the treatment of sepsis-related coagulopathy has been widely investigated. Recent studies have found that there is a coagulation-inflammation cross-reaction system with platelet-leukocyte aggregates as the core pathogenesis of sepsis [7]. With inhibition of platelet activation by antiplatelet drugs being used to treat sepsis/acute lung injury, the high risk of patients could be reduced organ
damage and alleviated conditions [8, 9]. Former studies have found that P2Y12 receptor antagonists such as clopidogrel and ticagrelor treat sepsis and lung damage through anti-platelet aggregation effects [10–12]. Their main mechanism is to prevent the formation of neutrophil-platelet aggregates by inhibiting the recruitment of neutrophils, significantly reducing thrombocytopenia, and also reducing lung damage caused by sepsis, although the therapeutic mechanism of cangrelor on sepsis has not been reported. Our research aims were to characterize the potential effect of cagrelor on sepsis and to identify its mechanism of action.

**Materials And Methods**

**Drugs and reagents**

Cangrelor (98% pure) was obtained from Vcare PharmaTech Co., Ltd (Shanghai, China). Myeloperoxidase (MPO) kit were obtained from Nanjing Jiancheng (Jiangsu, China). BCA Protein Assay was obtained from Thermo Fisher (MA, USA). anti-CD40L (#15094, 1:1000) and β-actin (#4970, 1:1000) were obtained from Cell Signalling Technology (MA, USA). Anti-GPR17 (ab75553, 1:500) was obtained from Abcam (Shanghai, China). Enzyme-linked immunosorbent assay (ELISA) kits were obtained from RapidBio (CA, USA). TRIzol reagent was obtained from Life Technology (CA, USA). PrimeScript® RT Master Mix and SYBR® Premix Ex Taq™ were purchased from Takara (Dalian, China). All other reagents were obtained from Sigma-Aldrich (Shanghai, China).

**Animal Treatment**

C57BL/6 mice (20 ± 2 g) were purchased from Shanghai Laboratory Animal Center (Shanghai, China) and fed according to guidelines approved by the Experimental Animal Ethical Committee of Pudong New Area Gongli Hospital. They were raised in a constant temperature and humidity room (22 ± 1 °C, 65 ± 5% humidity) with standard diet and water. For the survival study, 58 mice were were randomly separated into four groups: (1) sham (n=8), (2) cecal ligation and double puncture (CLP) (n=18), (3) CLP + cangrelor (5 mg/kg) (n=18), and (4) CLP + cangrelor (20 mg/kg) (n=18). Another 32 mice were randomly separated into four groups: (1) sham(n=8), (2) cecal ligation and double puncture (CLP) (n=8), (3) CLP + cangrelor (5 mg/kg) (n=8), and (4) CLP + cangrelor (20 mg/kg) (n=8). The CLP was performed on isoflurane-anesthetized mice as previously described [13, 14]. Sham control animals underwent a laparotomy without ligation or double puncture. Mice were orally administrated with cangrelor (5 or 20 mg/kg) 2 h before surgery. After surgery but prior to emergence, mice were fluid-resuscitated (1 mL/mouse of sterile saline, subcutaneously). Mice were sacrificed 24 h after induction of CLP, plasma and lung were saved.

**Masson staining of the lung**
Paraffin sections of lung tissues were analyzed after several methods containing dewaxing rehydration, Ponceau S Fuchs in acid solution staining for 300 seconds, by washing in 1% phosphomolybdic acid differentiation solution for 5 min, aniline blue solution counterstaining for 300 seconds, with 1% glacial acetic acid for 1 min, alcohol gradient dehydration, transparency production using dimethylbenzene and xylene, and mounting.

**Flow cytometry**

For detect of surface CD40L expression on platelets, plasma were placed for 10 min at 36.5°C that blocked FcγIII/II receptors in order to decrease nonspecific labeling, next incubated with fluorescein isothiocyanate-conjugated anti-CD41. Immobilization of cells with 1% formaldehyde; erythrocytes were lysed with fluorescence-activated cell sorting lysing solution (BD Biosciences, Shanghai, China), and neutrophils and platelets were then recovered by centrifugation at 300 × g for 10 min. Platelet activation was analyzed by using PE-conjugated JON/A antibody (Emfret Analytics, Wuerzburg, Germany), which bound to the high affinity conformation of mouse affini.

**RNA isolation and quantitative real-time PCR (QRT-PCR)**

mRNA was obtained using TRIzol, respectively. cDNA was synthesised using M-MLV reverse transcriptase and Sangon reverse transcription primers. Relative transcript abundance was determined by the 2−ΔΔCt method and mRNA expression was normalised against β-actin. All amplification analyses were completed on QuantStudio™ 6 Flex Real-Time PCR System.

**Protein extraction and western blot analysis**

Lung tissues were lysed by RIPA buffer and protein concentrations were assessed by the BCA protein assay. About 20 μg of protein from each example was divided by a 10% SDS-polyacrylamide gel and transferred to polyvinylidene fluoride membranes. Membranes were blocked with 10% skim milk in TBST and incubated with primary antibodies overnight at 4°C. Membranes were incubated with the corresponding secondary antibody for 1 h at room temperature and washed in TBST. Protein signals were detected using the Super ECL Plus Detection Reagent.

**Enzyme-linked immunosorbent assay (ELISA)**

Concentrations of the inflammatory cytokines in mice serum were measured with an ELISA kit following to manufacture protocols.
Statistical Analysis

The effects of Cang on the survival of mice were analyzed using the Kaplan–Meier curve and log-rank test. All other results were analyzed using one-way ANOVA analysis by SPSS statistical software for Windows, version 22.0 (SPSS, Chicago, IL, USA). The measurement data are expressed as the mean ± SD. A value of $p < 0.05$ was deemed statistically significant.

Results

Cangrelor alleviates CLP-induced pulmonary injury.

First, as shown in Fig. 1, the survival rate was 72.22% on the first 24 h, decreased to 55.56% on the next 24 h, and decreased a stable level of 38.89% on 72 h after CLP. Treating with 5 mg/kg Cangrelor did not enhance the survival rate compared with CLP group, while treating with 20 mg/kg Cangrelor significantly improved the survival rate compared with CLP group. Next, HE staining showed noticeable histopathologic changes including congestion, inflammatory cell infiltration, necrosis and degeneration while treating with 20 mg/kg Cangrelor significantly ameliorate the histopathologic changes induced by CLP (Fig. 2A). What’s more, we assessed the levels of apoptosis in mice lung tissues, using a TUNEL assay. The results showed that in the CLP group, lung tissues had a higher level of apoptotic cells, but cangrelor (20 mg/kg) reversed this result (Fig. 2B). Next, we assessed the anti-inflammatory effect of cangrelor. Masson staining showed that CLP mice had fibrotic changes, while there was significantly less damage in the CLP + cangrelor (20 mg/kg) group, as showed by blue staining (Fig. 2C).

Cangrelor regulates platelet aggregation and neutrophil recruitment.

The platelets surface level of CD40L was measured (Fig. 3A). The mean fluorescence intensity (MFI) was 72 in the sham group and 41 in the CLP group. After the administration of cangrelor, the MFI was 46 when treated with 5 mg/kg cangrelor and 91 when treated with 20 mg/kg cangrelor. Western blotting also presented that the level of platelet CD40L was meaningfully decreased in the CLP group in contrast to the sham group, while cangrelor (20 mg/kg) increased this reduction (Fig. 3B). A cell assay of the bronchoalveolar lavage fluid (BALF) indicated the neutrophils in the bronchoalveolar was 0.26 × 10⁶ in the sham mice while it was 1.76 × 10⁶ when induced by CLP. After cangrelor treatment, the number of neutrophils decreased to 0.87 × 10⁶ (Fig. 3C). In addition, the pulmonary wet/dry ratio in the CLP group increased, which indicated the formation of pulmonary edema. However, treatment with 20 mg/kg cangrelor significantly reversed this edema (Fig. 3D).

Cangrelor ameliorates the inflammatory response through GPR17.

CLP-induced levels of MPO in mice lung tissues were significantly increased, whereas they decreased significantly in the presence of cangrelor (Fig. 4A). Using an ELISA, the concentrations of TNF-α, IL-1β,
and IL-6 in mice serum were meaningfully raised in the presence of CLP; however these levels were reduced by cangrelor (20 mg/kg) (Fig. 4B). Former research has reported that cangrelor is the antagonist of GPR17 [15]. As shown in Fig. 4C and D, western blotting and RT-PCR results indicated CLP upregulated GPR17 level in lung tissues, whereas the administration of cangrelor (20 mg/kg) decreased its expression.

**Discussion**

In our research, we demonstrated that cangrelor alleviated CLP-induced lung injury in abdominal sepsis by regulating platelet aggregation and the inflammatory response.

Platelets have a very important function in hemostasis, and are recognized for their capability to regulate immune responses [16]. The P2Y12 receptor belongs to a protein-coupled receptor and is one of two receptors on platelets. The P2Y12 receptor is also the initiation channel for platelet activation, and the receptor strongly amplifies signal activation. This amplification is displayed not only in the magnification of the platelet aggregation signal, as well as in subsequent multi-step signaling, including the release of platelet particles and the enhancement of platelet-promoting activity [17, 18]. Therefore, this it is an ideal therapeutic target.

Previous studies reported that P2Y12 receptor antagonists such as clopidogrel and ticagrelor alleviate sepsis and lung damage through anti-platelet aggregation [10–12]. In addition, increasing evidence has shown that P2Y12 receptor antagonists decrease the inflammatory response in cardiovascular events, thrombosis, and atherosclerosis [19, 20], which indicates that P2Y12 regulation can affect inflammation through mechanisms that have not yet been fully clarified. Cangrelor is a second-generation P2Y12 antagonist, and a clinically used thienopyridine antiplatelet drug. However, previous studies have not yet fully clarified it mechanisms of action. Cangrelor is a second-generation P2Y12, and past studies have found that cangrelor alleviates the inflammatory response in lung fibrosis [21], chronic inflammatory pain [22], and neuropathic pain [23]. In the present study, we found that cangrelor decreased CLP-induced pulmonary injury by modulating the inflammatory response.

Previous studies have also reported the release of soluble CD40L from platelets in sepsis-regulated platelet-dependent neutrophil lung accumulation [24, 25]. However, the mechanism for modulating CD40L platelet shedding in sepsis is not clear. In our study, CLP induced a decrease of surface CD40L, which was significantly increased after treatment with cangrelor. In addition, the increase of neutrophils in BALF was attenuated by cangrelor treatment. Cangrelor has been confirmed to effectively inhibit the expression of GPR17 [15, 26, 27]. There is increasing evidence that the modulation of GPR17 could ameliorate inflammatory responses and injury, which suggested that GPR17 plays an important role in injury reparation [28]. For example, inhibiting GPR17 repressed the activation of microglia and alleviated inflammation induced by ischemic in rats [26, 29]. Inhibition of GPR17 also protects against myocardial fibrosis caused by cardiac ischemia [30], and we further confirmed that the administration of cangrelor reversed the rise of GPR17 induced by CLP, as well as ameliorating the inflammatory response.
Conclusion

Our study suggested that cangrelor inhibited the expression of GPR17, thus alleviating the inflammatory response and the rise of neutrophils in BALF, to reverse CLP-mediated pulmonary injury during sepsis.
