Abstract

Orofacial clefts (OFC; MIM 119530) are among the most common major birth defects. Here, we carried out mutation screening of the PVR and PVRL2 genes, which are both located at an OFC linkage region at 19q13 (OFC3) and are closely related to PVRL1, which has been associated with both syndromic and non-syndromic cleft lip and palate (nsCLP). We screened a total of 73 nsCLP patients and 105 non-cleft controls from the USA for variants in PVR and PVRL2, including all exons and encompassing all isoforms. We identified four variants in PVR and five in PVRL2. One non-synonymous PVR variant, A67T, was more frequent among nsCLP patients than among normal controls, but this difference did not achieve statistical significance.

Key words: PVR, PVRL2, cleft lip and palate, mutation, SSCP.

Orofacial clefts (OFC) are common birth defects, occurring in approximately 1 per 800 North American Caucasian infants and varying in incidence among patients of different geographical origins (Vanderas, 1987). Most cases of OFC (70%) occur sporadically, and may include isolated cleft lip, cleft lip with or without palate (CLP) and isolated cleft palate. Such ‘non-syndromic’ OFC appear to be polygenic in origin, a number of loci each exerting a relatively modest effect against a multi-factorial background (Spritz, 2001; Murray, 2002; Cobourne, 2004).

A role for one or more genes at chromosome 19q involved in non-syndromic CLP (nsCLP) has been supported by multiple lines of evidence. Genetic linkage studies defined OFC3, a region of genetic linkage to nsCLP on chromosome 19q13 (Stein et al., 1995; Warrington et al., 2006). Initial studies of candidate genes in the OFC3 region focused on BCL3, a number of genetic association studies finding conflicting evidence of association with nsCLP in various populations (Stein et al., 1995; Amos et al., 1996; Maestri et al., 1997; Gaspar et al., 2002; Blanco et al., 2004). Other genes studied in the OFC3 region include APOC2 (Marazita et al., 2002), CLPTM1 (Yoshiura et al., 1998; Turhani et al., 2005; Warrington et al., 2006), and TOMM40 (Warrington et al., 2006), each yielding, at best, inconsistent evidence for involvement in nsCLP.

Recent attention has turned to two other candidate genes in 19q13, PVR and PVRL2, which are paralogous to PVRL1, in which homozygous mutations result in a rare autosomal recessive CLP syndrome, CLPED1 (Suzuki et al., 2000), and in which variants have been genetically associated with nsCLP in northern Venezuela (Sözen et al., 2001) and perhaps other populations (Avila et al., 2006; Scapoli et al., 2006; Tongkobpetch et al., 2008). PVR, PVRL1, and PVRL2 respectively encode Necl-5/CD155, nectin-1 and nectin-2, cell adhesion molecules present at adherens junctions and other ectoplasmic specializations at cell-cell contacts (Young et al., 2009), and are widely expressed during development. Warrington et al. (2006) reported genetic association of a rare intronic variant in PVR, C__1828143_10 (rs35385129), with nsCLP in patients from several different populations, and by direct sequencing identified 7 variants in PVR and 16 in PVRL2, none of which appeared to be causal for nsCLP. A subsequent study found marginal association of nsCLP in Italian patients with PVR SNP rs35385129, but no association with a single intronic PVRL2 SNP analyzed (Pezzetti et al., 2007).
In the present study, we carried out mutation analyses of \(PVR\) and \(PVRL2\) in USA Caucasian (CEU) patients with nsCLP and non-cleft controls. We obtained genomic DNA samples with informed consent from USA patients with nsCLP but with no other physical or cognitive abnormalities, and from unaffected controls. We initially screened all 8 exons of \(PVR\) and 10 exons of \(PVRL2\) (encompassing all known mRNA isoforms, except the last 21 nt of \(PVRL2\) exon 1) in 73 unrelated USA CEU nsCLP patients and 105 unrelated USA CEU controls. Subsequently, an additional 28 unrelated USA CEU nsCLP patients were specifically analyzed for the \(PVR\) rs1058402 (A67T) variant. The \(PVR\) and \(PVRL2\) PCR primers used are given in Table 1. PCR products were screened for variation by simultaneous single-stranded conformation polymorphism (SSCP)/heteroduplex analysis by electrophoresis in 0.5X MDE gels (Biowhittaker Molecular Applications) containing 10% glycerol (Lee et al., 1995), followed by DNA sequence analysis of those amplicons exhibiting aberrant SSCP/heteroduplex patterns.

As shown in Table 2, we identified a total of four variants in \(PVR\): rs11540085 (-1C > T), rs1058402 (A67T), rs203710 (I340M), and one novel variant, 19:49856876G > A (E404E). Similarly, we identified a total of five variants in \(PVRL2\): rs41290128 (D496N), rs283814 (P409P) and three novel variants, 19:50077328 G > A (A355T), 19:50081289T > C (F440F) and 19:50073660_50073661insAGG (R461-462ins). Most variants were observed in both patients and controls, except for the rare variant \(PVR\) 19:49856876G > A (E404E), which was observed in only one control, \(PVRL2\) 19:50077328G > A (A355T) and 19:50081289T > C (F440F), which we only observed in one and two patients, respectively, and 19:50073660_50073661insAGG (R461-462ins), which was observed in two controls. The allele frequency of the non-synonymous \(PVR\) variant, rs1058402 (A67T), in spite of being somewhat greater among nsCLP patients (0.039) than among controls (0.014), did not achieve statistical significance (\(p = 0.098\)). Likewise, genotype frequency distribution of the rs1058402 variant was not significantly different between nsCLP patients and controls.

The etiology of orofacial clefts is complex, most likely involving many different genetic and environmental factors, most of which remain unknown. Genetic association and linkage, besides studies, have implicated a region in chromosome 19q13, termed OFC3. Warrington et al. (2006) reported genetic association between nsCLP and a rare intronic variant in \(PVR\), rs35385129, in two distinct populations, although no association was found in two other patient groups (Warrington et al., 2006; Pezzetti et al., 2007). In spite of the statistically non-significant results here reported, our data suggest that \(PVR\) may bear further investigation.

Table 1 - Oligonucleotide primers for PCR amplification of the exons of \(PVR\) and \(PVRL2\).

| Amplicon | Primer sequences | Amplicon size (bp) |
