(October 23, 1996)

The Bethe ansatz equation is solved to obtain analytically the leading finite-size correction of the spectra of the asymmetric XXZ chain and the accompanying isotropic 6-vertex model near the antiferromagnetic phase boundary at zero vertical field. The energy gaps scale with size \(N\) as \(N^{-1/2}\) and their amplitudes are obtained in terms of level-dependent scaling functions. Exactly on the phase boundary, the amplitudes are proportional to a sum of square-root of integers and an anomaly term. By summing over all low-lying levels, the partition functions are obtained explicitly. Similar analysis is performed also at the phase boundary of zero horizontal field in which case the energy gaps scale as \(N^{-2}\). The partition functions for this case are found to be that of a non-relativistic free fermion system. From symmetry of the lattice model under \(\pi/2\) rotation, several identities between the partition functions are found. The \(N^{-1/2}\) scaling at zero vertical field is interpreted as a feature arising from viewing the Pokrovsky-Talapov transition with the space and time coordinates interchanged.

I. INTRODUCTION

Spectral properties of the asymmetric XXZ chain and its associated lattice model, the asymmetric 6-vertex model, have been of much interest recently [1, 2]. The asymmetric XXZ chain is a non-hermitian generalization of the standard spin 1/2 XXZ chain [3] and is the anisotropic limit of the row-to-row transfer matrix of the asymmetric 6-vertex model, i.e. the general 6-vertex model in horizontal and vertical fields [4]. Both models are solvable by the Bethe ansatz for arbitrary interaction parameter \(\Delta\), horizontal field \(H\) and vertical field \(V\), and for the lattice model, also for arbitrary anisotropy parameter.

When the interaction parameter \(\Delta\) is less that \(-1\), the asymmetric XXZ chain and the asymmetric 6-vertex model are antiferromagnetically ordered for small values of \(H\) and \(V\). (We use the term antiferromagnetic phase to denote the antiferroelectric phase of the lattice model.) The ordered phase in the \(H-V\) plane is bounded by the antiferromagnetic phase boundary beyond which the systems are disordered. The disordered phase is critical in that excitations are massless and correlation lengths decay algebraically. For still larger values of fields, complete ferromagnetic ordering sets in. The free energy of the 6-vertex model as a function of the two fields can be interpreted as the equilibrium crystal shape [5] and the antiferromagnetically ordered region of fields corresponds to the flat facet, and the antiferromagnetic phase boundary to the facet boundary. On the facet boundary, the curvature of the free energy surface is universal [6]. The nature of phase transitions at the facet boundary can be understood from the view point of domain wall excitations and is that of the Pokrovsky-Talapov (PT) transition [7].

Within the critical phase and on the phase boundaries, there exist infinite number of massless excitations in the thermodynamic limit. When the system size, i.e. the number of spins in the chain \(N\), is finite, the degeneracies are lifted producing energy gaps. Finite-size scaling of these energy gaps gives valuable information on the properties of the system [8]. Throughout the critical phase of the asymmetric XXZ chain and the asymmetric 6-vertex model, the energy gaps scale as \(N^{-1}\), and as shown in [9], the finite-size scaling amplitudes can be accounted for by the central charge \(c=1\) conformal field theory [10], with suitable modifications to account for incommensurate arrow densities. All finite-size scaling information are encoded in the \(O(1)\) part of the partition function which is covariant under the modular transformations and, for the case of the asymmetric 6-vertex model, is given by the modified Coulombic partition function.

When \(\Delta > 1\) and \(V = 0\), the critical phase is bounded by the so-called stochastic line where the asymmetric XXZ chain Hamiltonian describes time evolution of the single-step model [11] which is one of the simplest realization of the Kardar-Parisi-Zhang (KPZ) universality class of non-equilibrium growth models [12], and also of the driven lattice gas [13]. On the stochastic line, the \(N^{-1}\) scaling crossovers to the KPZ type \(N^{-3/2}\) scaling where the exponent \(3/2\) is the dynamic exponent for the 1+1 dimensional KPZ class. This has been shown first in [14] for a special limit, and numerically in [15] for other cases. More recently, it was shown in [16] which will be denoted as I in this work, that the energy gaps for general cases can be systematically expanded in power series of \(N^{-1/2}\) and the scaling amplitudes are...
given by level-dependent, but universal, scaling functions.

Recently, the finite-size scaling on the antiferromagnetic phase boundary of \( V = 0 \) is discussed by Albertini et al. \[1\]. In their work, it was shown analytically that the low-lying excitations satisfy the energy-momentum relation \( \varepsilon \sim \sqrt{k} \) in the thermodynamic limit which in turn indicates the \( N^{-1/2} \) scaling of energy gaps. That the energy gaps scale as \( N^{-1/2} \) was then confirmed by numerical solutions of the Bethe ansatz equations for finite \( N \).

In this work, we present analytic solutions for the finite-size scaling at the antiferromagnetic phase boundary using the method developed in I. It is seen that the \( N^{-1/2} \) scaling of energy gaps for \( V = 0 \) phase boundary arises from the same mathematical origin as in the case of the stochastic line. The scaling amplitudes for general levels are given in terms of a scaling variable \( u \sim (H - H_c)N \) where \( H_c \) is the position of the phase boundary at \( V = 0 \). Their crossover behaviors enable one to identify the class of levels which become degenerate at the phase boundary of \( |H| < H_c \). At \( H = H_c \), the energy gap amplitudes are found to be proportional to a sum of square-root of integers and an anomaly term. Furthermore, the \( O(1) \) part of the partition function in the scaling limit, which is simply called the partition function in this work, is also obtained for both the chain and the lattice model in terms of several infinite products involving non-integer powers of nome. Similar analysis is also carried out at the phase boundary of \( H = 0 \). Here, the energy gaps scale as \( N^{-2} \) which is a characteristic of the PT transition. Also the corresponding partition functions are evaluated and shown to be that of the non-relativistic free fermion system with dispersion relation \( \varepsilon \sim k^2 \). Using physical requirement of invariance of the partition function of the lattice model under exchange of rows and columns, i.e. under \( \pi/2 \) rotation of the lattice, we find interesting mathematical identities between infinite products. We also argue that the \( N^{-1/2} \) scaling at the \( V = 0 \) phase boundary is a feature arising from viewing the standard PT transition of the \( H = 0 \) phase boundary after \( \pi/2 \) rotation.

This paper is organized as follows. In Section II, we set notations and review the Bethe ansatz method for bulk properties. Then we discuss classifications of low-lying excitations. In Section III, the formalism for calculating finite-size corrections in energy is developed in line with I and the leading order solution is expressed in terms of level-dependent scaling functions with the scaling variable \( u \). In Section IV, the crossover behaviors of the energy gaps for \( H > H_c \) and \( H < H_c \) are discussed. From this, the class of excitations which remain massless at the facet boundary of \( |H| < H_c \) is identified. In Section V, the spectra and the partition functions at \( H = H_c \) are derived. We discuss in Section VI the spectra and the partition functions at the antiferromagnetic phase boundary of \( H = 0 \). From this, we obtain several identities between infinite products. Finally, we summarize and discuss our results in Section VII. Some mathematical details are relegated to Appendices. Appendix A proves some properties of the scaling function, Appendix B shows the details of derivations for the partition function at the \( V = 0 \) phase boundary, while Appendices C and D derive the spectra and the partition function, respectively, at the \( H = 0 \) phase boundary.

II. BETHE ANSATZ AND ENERGY LEVELS

We consider the asymmetric XXZ chain of \( N \) sites whose Hamiltonian is given by

\[
\mathcal{H} = (2\sinh \lambda)^{-1} \sum_{i=1}^{N} \left( \cosh \frac{\lambda}{2} (\sigma_i^z \sigma_{i+1}^z - 1) - e^{2H} \sigma_i^+ \sigma_{i+1}^- + e^{-2H} \sigma_i^- \sigma_{i+1}^+ \right) \tag{1}
\]

where \( \sigma_i^a \) are the Pauli spin operators, \( \sigma_i^{a_+} = \sigma_i^a \), and \( H \) is the horizontal field. The standard interaction parameter \( \Delta \) has been parametrized as \( \Delta = - \cosh \lambda \) with \( \lambda > 0 \) since we are interested in the region \( \Delta < -1 \). The front factor is included for later conveniences. Below we use the short notation

\[
\alpha = \exp(-2\lambda). \tag{2}
\]

We also use the notation for the magnetization as

\[
\sum_{i=1}^{N} \sigma_i^z = N - 2Q = 2r \tag{3}
\]

where \( Q \) is the number of down spins and use

\[
q = Q/N = \frac{1}{2} - \frac{r}{N} \tag{4}
\]

so that \( 0 \leq q \leq 1 \) and \( r \) takes the integer (half-integer) values for \( N \) even (odd). We work in sectors of general but finite \( r \) as \( N \to \infty \). Since the spectra of Eq. (1) is symmetric with respect to \( H \) and \( r \), we work in the region of \( H \geq 0 \)
and \( r \geq 0 \). When a vertical field \( V \) is present, it contributes an additional energy \(-2rV\) in Eq. (3) but we set \( V = 0 \) except in Section VI where the spectra of the \( H = 0 \) phase boundary are discussed.

The eigenvalues \( E \) of \( \mathcal{H} \) in the sector \( Q \) are given by

\[
E = \sum_{j=1}^{Q} f_E(x_j)
\]  

(5)

where

\[
f_E(x) = \frac{x}{x - 1} - \frac{\alpha x}{1 - \alpha x}
\]  

(6)

and \( \{x_j\} \) are the solution of the Bethe ansatz equation

\[
\left( e^{2H - \lambda} \frac{x_i - 1}{1 - \alpha x_i} \right)^N = (-1)^{Q-1} \prod_{j=1}^{Q} \frac{x_i - \alpha x_j}{x_j - \alpha x_i} \quad (i = 1, 2, \ldots, Q).
\]  

(7)

(The roots \( \{x_j\} \) are related to the \( \{\alpha_j\} \) notation of [1,7,8] by \( x_j = \exp(\lambda - i\alpha_j) \).)

The asymmetric XXZ Hamiltonian is the logarithmic derivative of the asymmetric 6-vertex model row-to-row transfer matrix at the extreme anisotropic limit [5]. The eigenvalues \( \Lambda \) of the latter are also expressed in terms of \( \{x_j\} \). In this work, we consider the isotropic 6-vertex model, or the F model, in external fields whose six Boltzmann weights are given as \( \omega_{1,2} = \exp(\pm(H + V)) \), \( \omega_{3,4} = \exp(\pm(H - V)) \) and \( \omega_{5,6} = 2 \cosh(\lambda/2) \), respectively. The transfer matrix eigenvalues of the F model are given as

\[
-\ln \Lambda = -HN - 2rV - \sum_{j=1}^{Q} f_F(x_j)
\]  

(8)

where

\[
f_F(x) = \ln \frac{x - \exp(-\lambda)}{1 - \exp(-\lambda)x}
\]  

(9)

for \( H > 0 \). Following discussions can be easily extended to the anisotropic 6-vertex model but we consider only the isotropic case for simplicity. We define the phase function or the counting function \( Z_N(x) \) by

\[
iZ_N(x) = 2H - \lambda + (1 - q) \ln x + \ln \frac{1 - x^{-1}}{1 - \alpha x} + \frac{1}{N} \sum_{j=1}^{Q} f_Z(x, x_j)
\]  

(10)

with

\[
f_Z(x, x') = \ln x' - \ln \frac{1 - \alpha x'/x}{1 - \alpha x/x'} = \ln x' + \sum_{|n| \neq 0} \frac{\alpha^{|n|}}{n} \left( \frac{x' - x}{x} \right)^n
\]  

(11)

and the root density function \( R_N(x) \) by the derivative of \( Z_N \) as

\[
R_N(x) = i x Z'_N(x)
\]  

\[
= -q + \frac{x}{x - 1} + \frac{\alpha x}{1 - \alpha x} + \frac{1}{N} \sum_{j=1}^{Q} f_R(x, x_j)
\]  

(12)

where

\[
f_R(x, x') = -\sum_{|n| \neq 0} \alpha^{|n|} \left( \frac{x' - x}{x} \right)^n
\]  

(13)

with \( \sum_{n \neq 0} \) denoting the sum over all integers except 0. In terms of \( Z_N \), the Bethe ansatz equation can be rewritten as
\[ Z_N(x_j) = \frac{2\pi}{N} I_j \]  

where \( I_j \) are half-integers (integers) for \( Q \) even (odd). The ground state for each \( Q \) is obtained if one chooses \( I_j \) as

\[ \frac{2\pi}{N} I_j = \frac{2\pi}{N} \left( -\frac{Q+1}{2} + j \right) \equiv \phi_j, \]  

for \( j=1,2,\ldots,Q \). In the thermodynamic limit, \( \{x_j\} \) for the ground state form a continuous curve given by the locus \( x = Z^{-1}_N(\phi) \) for \(-\pi q \leq \phi \leq \pi q\) where \( Z^{-1}_N(\phi) \) denotes the inverse function of \( Z_N(x) \).

The simplifying feature for the case of \( q = 1/2 \) and \(|H| \leq H_c\) is that the root contour becomes closed in the \( x\)-plane as for the case of the stochastic line. Here, \( H_c \) is the antiferromagnetic transition point to be given in Eq. (21).

To find actual form of \( R_\infty(x) \) for \( q = 1/2 \) and \(|H| < H_c\), one may evaluate the sum in Eq. (10) by a contour integration over the circle \(|x| = \exp(\lambda - b)|\) with \(-\lambda < b < \lambda\) using the known expression

\[ R_\infty(x) = \sum_n \frac{\alpha^n}{1 + \alpha^n} x^n \]  

with \( \sum_n \) denoting the sum over all integers and \( 1 < |x| < 1/\alpha \). The result is

\[ iZ_\infty(x) = 2H - \lambda + \frac{1}{2} \ln x + \frac{1}{2} \ln |x_0| + \sum_{n \neq 0} \frac{\alpha^n}{n(1 + \alpha^n)} (x^n + x^n_0) \]  

where \( x_0 \equiv \exp(\lambda - b + \pi i) \) is the end point of the contour. The conditions \( Z_\infty(\exp(\lambda - b \pm \pi i)) = \pm \pi/2 \) are met if \( H \) is related to \( x_0 \) or \( b \) by

\[ 2H = \lambda - \ln |x_0| - 2\sum_{n \neq 0} \frac{\alpha^n}{n(1 + \alpha^n)} x^n_0. \]  

It is convenient to use the real function \( \Xi(b) \) defined by

\[ \Xi(b) = \frac{b}{2} + \sum_{n=1}^{\infty} \frac{(-1)^n \sinh nb}{n \cosh n\lambda} \]

\[ = \ln \frac{\cosh(\lambda + b)/2}{\cosh(\lambda - b)/2} - \frac{b}{2} - \sum_{n=1}^{\infty} \frac{(-1)^n \alpha^n \sinh nb}{n \cosh n\lambda}. \]  

Eq. (18) is then the same as

\[ H = \Xi(b) \]  

while \( R_\infty(x_0) = \Xi'(b) \) with ‘ denoting the derivative with respect to \( b \).

As \( b \) varies from 0 to \( \lambda \), \( x_0 \) moves from \(-e^\lambda \) to \(-1\) and \( H \) increases from 0 to

\[ H_c = \Xi(\lambda). \]  

It turns out that the critical value \( H_c \) is indeed the value of the antiferromagnetic phase boundary at \( V = 0 \). Moreover the entire antiferromagnetic phase boundary of the lattice model is described by the \( H \)-dependent critical vertical field \( V_c \) given by

\[ V_c = \Xi(\lambda - b) \]  

(lattice)

with \(-2\lambda < b < 2\lambda\). That of the asymmetric XXZ chain with normalization as given in Eq. (1) is given by (See Appendix C)

\[ V_c = \Xi'(b) \]  

(chain).

Typical phase diagrams in the \( H-V \) plane are shown in Fig. 1.

The bulk ground state energy per site for \(|H| \leq H_c\) is given as

\[ e_\infty \equiv \lim_{N \to \infty} E/N = -e_0 \]  

where
\[ c_0 = \frac{1}{2} + 2 \sum_{n=1}^{\infty} \frac{\alpha^n}{1 + \alpha^n}, \] (24)

and the bulk free energy of the F model is \( f_\infty \equiv \lim_{N \to \infty} (N - \ln \Lambda)/N = -\lambda/2 - \sum_{n=1}^{\infty} n^{-1} \alpha_n^{n/2} \tanh n\lambda. \)

In the antiferromagnetic phase, finite mass gaps appear in the energy spectra. But these mass gaps are offset by fields and at the antiferromagnetic phase boundary, infinite number of other levels become degenerate with the ground state in the thermodynamic limit. These degeneracies are lifted for finite but large \( N. \) Our aim here is to find these finite-size corrections for arbitrary energy levels. We denote these energy gaps as \( \Delta E \) and \( \Delta F, \) respectively: \( \Delta E = E - e_\infty N \) and \( \Delta F = -\ln \Lambda - f_\infty N. \)

The ground state characterized by Eq. (13) corresponds to a Fermi sea as depicted in Fig. 2(a) for \( r=0. \) Other energy levels are obtained if other sets of \( \{I_j\} \) are chosen. An important class of levels is the \( m \)-shifted levels where \( \{I_j\} \) are shifted by an integer \( m \) from that of the ground state, i.e. \( 2\pi I_j/N = \phi_{j+m}. \) These states are denoted as \( (r,m,0). \) Fig. 2(b) shows the 1-shifted level \( (0,1,0). \) Further excitations are obtained by creating from the \( m \)-shifted states an equal numbers of particles and holes near the two ends of the Fermi sea. Excited levels are then characterized by their particle and hole positions. The particle (hole) positions near the right-hand side of the Fermi sea can be specified by a set of integers \( \{p_k\}, \) \( \{h_k\} \) which are related to the index \( j \) in \( \phi_j \) as \( j = Q + m + p_k (Q + m + 1 - h_k), \) for \( k=1,2,\ldots,n_+, \) \( n_+ \) being the number of particle-hole pairs, and \( 1 \leq p_1 < p_2 < \cdots < p_{n_+} \) \( (1 \leq h_1 < h_2 < \cdots < h_{n_+}). \) Particles (holes) near the left-hand side may be labeled similarly by \( \{p_k\} \) \( \{h_k\} \) with \( j = 1 + m - p_k (m + h_k), \) for \( k=1,2,\ldots,n_- \) and \( 1 \leq p_1 < p_2 < \cdots < p_{n_-} \) \( (1 \leq h_1 < h_2 < \cdots < h_{n_-}) \). Such excitation configurations are denoted collectively by \( \mathcal{P}. \) General levels are then labeled as \( (r,m, \mathcal{P}). \) Fig. 2(c) shows a level obtained by creating \( n_+ = 2 \) particle-hole pairs at the right-end and \( n_- = 1 \) pair at the left-end from the 1-shifted level of Fig. 2(b). In \( \mathcal{P}, \) it was shown for the critical region that levels obtained in this way account for all the low-lying excitations which are expected to appear from the central charge \( c = 1 \) conformal field theory. Here, we also assume that all the low-lying excitations are generated in this manner.

When the particle-hole configurations differ from the ground state only at finite distances away from the two ends of the Fermi sea, finite-size corrections in energies are determined by the analytic property of \( Z_\infty(x) \) near \( x = x_0. \) However, the root density vanishes at \( x = x^0_\epsilon = e^{\pi i} \) which is the end point of the root contour for \( H = H_c. \) Therefore \( Z_\infty^{-1}(\phi) \) exhibits a square root singularity at \( \phi = \pm \pi/2. \) The same phenomenon was the origin of the unusual \( N^{-3/2} \) scaling of the energy gaps along the stochastic line and one can expect similar mechanism produces \( N^{-1/2} \) scaling in the present case. On the other hand, for \( |H| < H_c \) \( O(N^{-1}) \) variations in \( \phi \) near \( \phi = \pm \pi/2 \) cause, via \( Z_\infty^{-1}(\phi), \) \( O(N^{-1}) \) variations in \( x \)-plane and hence the finite-size corrections take the form of power series in \( N^{-1}. \) What is special at the antiferromagnetic phase boundary is that the real parts of the energy gaps scale as \( N^{-2} \) which is the characteristic of the PT transition. These features are born out explicitly below.

### III. ENERGY GAPS FOR \( H \) NEAR \( H_C \)

In this section, we derive the leading order finite-size correction of the energy gaps \( \Delta E \) and \( \Delta F \) for general levels with \( (H - H_c)N \) as a scaling variable. Readers not interested in details may skip to Eqs. (12) and (14) which are the main results of this section.

To find the energy gaps for \( H \) near \( H_c, \) we employ the method of I. Thus, for finite but large \( N \) and for levels whose energies are close to that of the ground state, we assume, following I, that there exists in the complex \( x \)-plane a point \( x_c \) near \( x^0_\epsilon = e^{\pi i} \) such that \( Z_N(x_c) = 0, \) \( Z_N(x) \) itself having a branch cut passing through \( x_c, \) and that near \( x_c, \) \( Z_N(x) \) has the expansion of the form

\[ iZ_N(x) = \pm i\pi q + y_\pm \frac{\pi}{N} + \frac{1}{a_1^2}(x - x_c)^2 + O((x - x_c)^3) \] (25)

where the upper (lower) sign refers to the assumed value of \( iZ_N(x) \) at \( x = x_c \) \( (x = x_c e^{-2\pi i}). \) This amounts to assuming

\[ Z_N^{-1}(\pm \pi q + \frac{\pi}{N} \xi) = x_c^\pm \pm i a_1 \sqrt{y_\pm - i \xi} \sqrt{\frac{\pi}{N}} + O(N^{-1}) \] (26)

for \( \xi \sim O(1) \) with \( x^+_c = x_c \) and \( x^-_c = x_c e^{-2\pi i}. \)

The constants \( x_c, a_1, y_\pm, \) etc. are all level dependent and should be determined self-consistently. But, first we assume they are known and evaluate the finite sums of the form
to $O(1/\sqrt{N})$ for $f(x')$ given in Eqs. (31), (32), (11) and (13). Following the same steps as in I, but generalizing to levels with $m \neq 0$, we find

$$S[f] = \sum_{j=1}^{Q} f(x_j) = \sum_{j=1}^{Q} f(Z_N^{-1}(2\pi N I_j))$$ \hfill (27)

where the integral is over a closed contour in the annulus $1 < |x| < 1/\alpha$ and $Y_1(y_+, y_-)$ is defined below. To define $Y_1$, we first introduce two functions $J_+(y)$ and $J_-(y)$ of complex variable defined for $\Re y > 0$ and $\Im y < 0$, respectively, as

$$J_\pm(y) = \frac{1}{2i} \int_{0}^{\infty} \frac{\sqrt{y + t} - \sqrt{y - t}}{e^{\pi t} - 1} \, dt \pm \frac{i}{2} y^{1/2} - \frac{1}{3} y^{3/2}$$ \hfill (29)

with the branch cut of the square roots at the negative real axis. As shown in Appendix A, $J_\pm(y)$ satisfy the recursion relations

$$J_\pm(y \pm 2i) = J_\pm(y) \mp i\sqrt{y}.$$ \hfill (30)

Thus, we may extend the definition of $J_+(y)$ ($J_-(y)$) into the half plane $\Re y \leq 0$ ($\Re y \geq 0$) using the relation Eq. (30) recursively. Having defined $J_\pm(y)$, we then give the expression of $Y_1$ for general level $(r, m, P)$:

$$Y_1(y_+, y_-) = J_+(y_+ + i - 2im) + J_-(y_- - i - 2im)$$

$$+ i \sum_{k=1}^{n_+} \left( \sqrt{y_+ + i(1 - 2m - 2p_k)} - \sqrt{y_+ - i(1 + 2m - 2h_k)} \right)$$

$$- i \sum_{k=1}^{n_-} \left( \sqrt{y_- - i(1 + 2m - 2p_k)} - \sqrt{y_- + i(1 - 2m - 2h_k)} \right).$$ \hfill (31)

The first two terms in Eq. (31) are contributions for the $m$-shifted levels and the sums in the second (third) line accounts for particle-hole pairs created at the right- (left-) end of the Fermi sea. When $m = 0$ and $y_+ = y_- = Y_1(y, y)$ reduces to minus of $Y_1(y)$ defined in I.

Applying Eq. (28) to Eq. (12), we then obtain the solution for $R_N$ as

$$R_N(x) = R_\infty(x) + \frac{r}{N} + \frac{1}{N} \sum_{n \neq 0} \frac{a^{n}}{(1 + a^{n})^{n}} \left( \frac{x}{x_c} \right)^{n} \left( \frac{y_+ - y_-}{2i} \right) + \frac{n}{x_c} a_1 Y_1(y_+, y_-) \sqrt{\frac{\pi}{N}} + O(N^{-2}).$$ \hfill (32)

Having obtained $R_N(x)$ to $O(N^{-3/2})$, we can evaluate $S[f]$ to $O(N^{-1/2})$ for any $f(x)$. In particular, applying the general sum formula to $f(x') = f_Z(x, x')$, $Z_N(x)$ can be evaluated to $O(N^{-3/2})$. Evaluating the latter at $x = x_c$ and $x = x_c \exp(-2\pi i)$, we obtain two self-consistency equations (See Eq. (22).)

$$\pm i\pi q + \frac{\pi}{N} y_\pm = \pm i(1 - q)\pi + 2H - \lambda + 2 \sum_{n \neq 0} \frac{\alpha^n}{1 + \alpha^n} \frac{x_c^n}{n}$$

$$+ \left( 1 + \frac{2r}{N} - \frac{y_+ - y_-}{2N} \right) (\ln x_c - \pi i) + \frac{(2im - y_+ + y_-)}{2} \frac{\pi}{N}$$

$$+ 2\pi^{1/2} a_0 a_1 x_c^{-1} Y_1(y_+, y_-) N^{-3/2} + O(N^{-2})$$ \hfill (33)

where $c_0$ is given in Eq. (24). From Eq. (33), one first obtains $y_+ - y_- = 4ir$. Next, evaluating $R_N(x)$ and $R'_N(x)$ at $x_c$, we obtain two more self-consistency equations as

$$0 = R_\infty(x_c) + \frac{2c_0 r}{N} + O(N^{-2}),$$

$$\frac{2x_c}{a_1} = R'_\infty(x_c) + O(N^{-3/2})$$ \hfill (34)

(35)
where \( y_+ - y_- = 4i\pi \) has been used in Eq. (34). Solving Eqs. (34) and (33) perturbatively, we have

\[
x_c = e^{\pi i} + \frac{2r e_0}{e_1} - \frac{1}{N} + O(N^{-2}),
\]

\[
a_1 = \frac{\sqrt{2}}{e_1} + O(N^{-1})
\]

where \( e_1 \) is a positive real constant defined as

\[
e_1 \equiv (-R'_\infty (-1))^{1/2} = (-\Xi''(\lambda))^{1/2} = \left( \frac{1}{4} + 2 \sum_{n=1}^{\infty} \frac{n(-1)^n}{\alpha^n + 1} \right)^{1/2}.
\]

Using Eqs. (36) and (37) in Eq. (33), we find the leading order solution of \( y_{\pm} \) as

\[
y_{\pm} = (\pm 2r + m)i + u + O(N^{-1/2})
\]

where \( u \) is the scaling variable

\[
u = (H - H_c)N/\pi
\]

which is assumed fixed as \( N \to \infty \). Having determined \( y_{\pm}, x_c \) and \( a_1 \) to necessary orders, we are now in a position to evaluate \( \Delta E \) and \( \Delta F \). Applying Eq. (28) together with Eq. (32) to Eq. (6), we find

\[
E = -e_0 N - r + \frac{y_+ - y_-}{2i} + \sum_{n \neq 0} \frac{\min(1, \alpha^n)}{1 + \alpha^n} \left( \frac{y_+ - y_-}{2i} + N x_c^{-1} a_1 Y_1(y_+, y_-) \sqrt{\frac{\pi}{N}} \right) + O(N^{-1}).
\]

Inserting the solutions Eqs. (36), (37) and (39), to Eq. (41), the \( O(1) \) terms in Eq. (41) cancel out and we finally have, for \( V = 0 \),

\[
\Delta E \equiv E - e_\infty N = e_1 \frac{\sqrt{2\pi}}{N} + O(N^{-1})
\]

where \( e_\infty = -e_0, e_1 \) is given in Eq. (38) and \( Y_1^{(r,m,P)} \) is the value of \( Y_1(y_+, y_-) \) at \( y_{\pm} = u + (\pm 2r + m)i \):

\[
Y_1^{(r,m,P)} = J_+(u + i(2r - m + 1)) + J_-(u - i(2r + m + 1)) + i \sum_{k=1}^{n_+} \left( \sqrt{u + i(2r - m + 1 - 2p_k)} - \sqrt{u + i(2r - m + 1 + 2h_k)} \right) - i \sum_{k=1}^{n_-} \left( \sqrt{u - i(2r + m + 1 - 2p_k)} - \sqrt{u - i(2r + m + 1 + 2h_k)} \right).
\]

Here, \( J_\pm(y) \) and \( u \) are given in Eq. (29) and (40), respectively. \( Y_1^{(r,m,P)} \) regarded as a function of the scaling variable \( u \) is then the scaling function. Similar calculation for the F model leads, for \( V = 0 \),

\[
\Delta F \equiv -\ln \Lambda - f_\infty N = -i\pi m + e_2 \frac{\sqrt{2\pi}}{N} + O(N^{-1})
\]

where the constant \( e_2 \) is given as

\[
e_2 \equiv \Xi'(0) = \frac{1}{2} + \sum_{n=1}^{\infty} \frac{(-1)^n}{\cosh n\lambda}.
\]

Note that \( \Delta F \) has an imaginary term due to \( \Lambda \) being negative for \( m \) odd. Apart from this, all energy gaps scale as \( N^{-1/2} \) and all the level dependences are encoded in the scaling function \( Y_1^{(r,m,P)} \). Higher order corrections which come as a power series in \( N^{-1/2} \) can be calculated perturbatively using the method similar to that of I.
IV. CROSSOVER BEHAVIORS FOR $H \neq H_C$

Eqs. (42) and (44) are obtained with the scaling variable $u$ fixed. By considering the limits $u \to \pm \infty$, we can derive how the spectra crossover to those of the critical and massive phases. First consider the case $H > H_c$ where $u \to \infty$ as $N \to \infty$. From Eq. (23), one can show that, as $u \to \infty$,

$$J_{\pm}(u \pm ia) = -\frac{1}{3}u^{3/2} + \left(\frac{a}{8} - \frac{1}{4}\right)u^{-1/2} + O(u^{-3/2}).$$  \hspace{1cm} (46)

Using this in Eq. (43), $Y_1^{(r,m,p)}$ becomes,

$$Y_1^{(r,m,p)} = \frac{2}{3}u^{3/2} + imu^{1/2} + \left(\frac{m^2}{4} + r^2 - \frac{1}{12} + \tilde{N} + \overline{\tilde{N}}\right)u^{-1/2} + O(u^{-3/2})$$  \hspace{1cm} (47)

with $\tilde{N} = \sum_{k=1}^{n_u}(p_k + \hat{h}_k - 1)$ and $\overline{\tilde{N}} = \sum_{k=1}^{n_F}(\hat{p}_k + \hat{h}_k - 1)$. The first term in Eq. (47) contributes a bulk energy term proportional to $(H - H_c)^{3/2}N$ to $\Delta E$ and $\Delta F$, the second an $O(1)$ imaginary term and the third a real one proportional to $(H - H_c)^{-1/2}N^{-1}$. These are exactly those which appear in the critical phase as shown in [2] and show the complete operator content of the Gaussian model. In the Coulomb gas picture, $m$ and $r$ are the spin wave and vortex quantum numbers, characterizing primary operators of the $c = 1$ conformal field theory whose Gaussian coupling constant $g$ is 2, and $\tilde{N}$ and $\overline{\tilde{N}}$ account for the conformal towers generated from the primary operators. Higher order corrections in Eqs. (22) and (44) not discussed here would give terms which are higher orders in $(H - H_c)$.

Next consider the case $H < H_c$. Now $u \to -\infty$ as $N \to \infty$ and one has to be careful about the branch cut of the square root. We find

$$J_{\pm}(u \pm ia) = \pm\frac{i}{3}u^{3/2} + G_{\pm}|u|^{1/2} + O(|u|^{-1/2})$$  \hspace{1cm} (48)

with $G_{\pm} = |a|^{-1}/2$ for $a > 0$ or for $a$ negative odd integers but, for $a \leq 0$ and even integers, $G_+ = (|a| - 1)/2$ while $G_- = (|a| + 3)/2$. Using this, we find the leading order of $Y_1^{(r,m,p)}$ for levels $(r,m,0)$ as $Y_1^{(r,m,0)} = max(2r, |m|)|u|^{1/2}$ if $(2r + m)$ is even and $Y_1^{(r,m,0)} = max(2r, |m - 1|)|u|^{1/2}$ if $(2r + m)$ is odd. Thus, when $m$ is in the range $-(2r + 1) < m \leq (2r + 1)$, $Y_1^{(r,m,0)} = 2r|u|^{1/2} + O(|u|^{-1/2})$. As to the contributions from particle-hole excitations in Eq. (43), we note that, for $-(2r + 1) < m \leq (2r + 1)$, particles at positions satisfying the conditions $2r - m + 1 - 2\hat{p}_k \geq 0$ or $2r + m + 1 - 2\hat{p}_k > 0$ contribute $-|u|^{1/2}$ but those violating the conditions and all holes contribute $|u|^{1/2}$. Thus when all particle positions satisfy the conditions, or equivalently, when the last positions satisfy the condition

$$- (2r + 1) < m \leq (2r + 1), \hspace{1cm} 2p_{n+} \leq 2r - m + 1, \hspace{1cm} 2\bar{p}_{n-} < 2r + m + 1,$$  \hspace{1cm} (49)

then all particle contributions are cancelled by holes. Thus, for such levels, $Y_1^{(r,m,p)} = 2r|u|^{1/2} + O(|u|^{-1/2})$ and $\Delta E$ becomes

$$\Delta E = 2\sqrt{2}\epsilon_1(H_c - H)^{1/2}r$$  \hspace{1cm} (50)

as $H \to H_c$ in the thermodynamic limit. This is the mass gap of the antiferromagnetic phase of the asymmetric XXZ chain. The mass gap for general $H$ is derived in [1] for levels $(r,0,0)$ and in agreement with Eq. (50). It is also derived for general $H$ implicitly in Eq. (C12) and is in accord with Eq. (23). Corresponding mass gap for the lattice model is

$$\Delta F = -i\pi m + 2\sqrt{2}\epsilon_2e_1^{-1}(H_c - H)^{1/2}r.$$  \hspace{1cm} (51)

For levels which do not satisfy Eq. (49), the mass gap becomes higher by $O(1)$. Eqs. (50) and (51) are valid for $r \geq 0$; they are valid for general $r$ if $r$ is replaced by $|r|$. When the vertical field $V$ is applied, both the chain and lattice model energy acquire a trivial term $-2rV$. When $2V$ is equal to the mass gap given in Eq. (50) and (51) for the chain and lattice model, respectively, all levels $(r,m,p)$ satisfying Eq. (49) and $r \geq 0$ become degenerate with the ground state energy in the thermodynamic limit. Finite-size corrections for these states will be discussed in Section V.

A special mention is needed for $r = 0$ which is the half-filled sector for $N$ even. Here, only two levels $(0,0,0)$ and $(0,1,0)$ satisfy Eq. (49). The latter which has momentum $\pi$ is the exponentially degenerate second largest eigenvalue of the transfer matrix as discussed in [22]. Such exponential degeneracy is reflected in the large $u$ behaviour of $Y_1^{(r,m,p)}$. When expanded as a power series in $|u|^{-1}$, both $Y_1^{(0,0,0)}$ and $Y_1^{(0,1,0)}$ have vanishing coefficients to all orders in the series.
V. SPECTRA AND PARTITION FUNCTIONS AT \( H_C \)

Now we consider the case \( H = H_C \) (The points A in Fig. 1). Since \( u = 0 \) in this case, one needs to evaluate \( J_{\pm}(ia) \) for integer values of \( a \). Successive application of the recursion relation Eq. (30) yields,

\[
J_{+}(ia) = \begin{cases} 
\sqrt{-1}\sum_{j=0}^{(a-3)/2} \sqrt{1+2j} - \sqrt{-ic_1} & \text{if } a > 0 \text{ and odd} \\
\sqrt{i}\sum_{j=0}^{(a+1)/2} \sqrt{1+2j} - \sqrt{-ic_1} & \text{if } a < 0 \text{ and odd} \\
\sqrt{-1}\sum_{j=0}^{(a-3)/2} \sqrt{2j} + \sqrt{-ic_2} & \text{if } a > 0 \text{ and even} \\
\sqrt{i}\sum_{j=0}^{(a+1)/2} \sqrt{2j} + \sqrt{-ic_2} & \text{if } a \leq 0 \text{ and even}
\end{cases}
\tag{52}
\]

and \( J_-(ia) = J_+(ia)^* \) where the positive numbers \( c_1 \) and \( c_2 \), called anomaly, are given as

\[
c_1 \equiv -J_{+}(i) / \sqrt{-1} = \frac{1}{6} \sum_{j=0}^{\infty} \frac{\sqrt{1+it} - \sqrt{1-it}}{e^{\pi t} - 1} dt
\tag{53}
\]

\[
c_2 \equiv J_{+}(0) / \sqrt{-1} = \zeta(3/2) / (2\sqrt{2}\pi) = 0.293 995 52 \ldots
\tag{54}
\]

with \( \zeta(z) \) the Riemann zeta function. We will see later in an indirect way that \( c_1 = (\sqrt{2} - 1)\zeta(3/2) / (4\pi) = 0.086 109 29 \ldots \) (Eq. (52)).

Using Eq. (52) in Eq. (43) with \( u = 0 \), one can read off \( Y_1^{(r,m,p)} \) for arbitrary levels. It is a sum of square-root of integers and the anomaly term. We give a few examples:

(i) Ground state in each sector \( r \) for \( N \) even:

\[
Y_1^{(r,0,0)} = \sqrt{2} \left( \sum_{j=0}^{r-1} \sqrt{1+2j} - c_1 \right).
\tag{55}
\]

(ii) \( m \)-shifted levels in sector \( r = 0 \):

\[
Y_1^{(0,m,0)} = \begin{cases} 
2\sqrt{3}\left(1 + \sqrt{3} + \cdots + \sqrt{m-1}\right) - \sqrt{2}c_1 & \text{for } m > 0 \text{ even} \\
2\sqrt{3}\left(\sqrt{2} + \sqrt{4} + \cdots + \sqrt{m-1}\right) + \sqrt{2}c_2 & \text{for } m > 0 \text{ odd.}
\end{cases}
\tag{56}
\]

For \( m < 0 \), \( Y_1^{(0,m,0)} \) is the complex conjugate of \( Y_1^{(0,|m|,0)} \).

(iii) \( m \)-shifted levels with \( -(2r+1) < m \leq (2r+1) \):

\[
Y_1^{(r,m,0)} = -\sqrt{2}c_1 + \sqrt{-i} \sum_{j=0}^{r-m/2-1} \sqrt{1+2j} + \sqrt{i} \sum_{j=0}^{r+m/2-1} \sqrt{1+2j}
\tag{57}
\]

for \((2r+m)\) even and

\[
Y_1^{(r,m,0)} = \sqrt{2}c_2 + \sqrt{-i} \sum_{j=0}^{r-(m+1)/2} \sqrt{2j} + \sqrt{i} \sum_{j=0}^{r+(m-1)/2} \sqrt{2j}
\tag{58}
\]

for \((2r+m)\) odd.

(iv) One particle-hole pair excitation from \((0,0,0)\):

\[
Y_1^{(0,0,p)} = -\sqrt{2}c_1 + \sqrt{i} \sqrt{2p_1 - 1} + \sqrt{-i} \sqrt{2h_1 - 1}
\tag{59}
\]

with the positive integers \( p_1 \) (\( h_1 \)) being the position of the particle (hole).

We have compared above predictions with existing numerical data of \( \Delta E \) obtained by solving the Bethe ansatz equation for finite \( N \) [23]. Extrapolations of available data \( (N \leq 80 \text{ for levels } (0,0,0) \text{ and } (1,0,0), N \leq 68 \text{ for } (0,2,0), N \leq 56 \text{ for } (2,0,0)) \) all show excellent convergence to the expected exact values.

Having obtained the leading finite-size corrections for arbitrary levels, one can go further to evaluate the partition functions in the scaling limit. We consider the partition function of the asymmetric XXZ chain at temperature \( T \) (in units of the Boltzmann constant) and the lattice model on \( N \times M \) lattice with periodic boundary conditions defined by \( \mathcal{Z}_E = \sum \exp(-\Delta E/T) \) and \( \mathcal{Z}_F = \sum \exp(-M\Delta F) \), respectively, where the sums are over all states and
the bulk part \( \exp(-Ne_\infty/T) \) for the chain and \( \exp(-MNf_\infty) \) for the lattice model has been taken out. To obtain a non-trivial limit, we take the thermodynamic limit with \( \sqrt{NT} \) or \( MN^{-1/2} \) fixed. In this scaling limit, the \( O(N^{-1/2}) \) part of the energy gaps produces finite contributions while levels which are not degenerate with the ground state in the thermodynamic limit need not be considered.

Considering \( Z_F \) first, and we can write from Eq. (44),

\[
Z_F = \sum \exp(-M\Delta F) = \sum (-1)^m M \exp(-\frac{c_2 M}{c_1} \sqrt{\frac{2\pi}{N}} \chi_j(r,m,p)).
\]

The sum is conveniently expressed in terms of a complex parameter \( q \) which we call nome:

\[
q = \exp(-\pi \sqrt{i\tau})
\]

where

\[
\tau = 2e^2 M^2 / (\pi e^2 N).
\]

Derivation of the partition function is relegated to Appendix B. Our final result for \( Z_F \) is

\[
Z_F(q) = \begin{cases} 
Z_1(q) \pm Z_2(q) + Z_3(q) & \text{for } M \text{ even} \\
\pm Z_1(q) + Z_2(q) \mp Z_3(q) & \text{for } M \text{ odd}
\end{cases}
\]

where the upper (lower) sign is for \( N \) even (odd) and \( Z_i(q) \) are defined as

\[
Z_1(q) = \frac{1}{2} (q\bar{q})^{-c_1} \prod_{j=-\infty}^{\infty} \left( 1 + q^{\sqrt{1+2j}} \right) \left( 1 + \bar{q}^{\sqrt{1+2j}} \right)
\]

\[
Z_2(q) = \frac{1}{2} (q\bar{q})^{-c_1} \prod_{j=-\infty}^{\infty} \left( 1 - q^{\sqrt{1+2j}} \right) \left( 1 - \bar{q}^{\sqrt{1+2j}} \right)
\]

\[
Z_3(q) = \frac{1}{2} (q\bar{q})^{c_2} \prod_{j=-\infty}^{\infty} \left( 1 + q^{\sqrt{3j}} \right) \left( 1 + \bar{q}^{\sqrt{3j}} \right)
\]

with \( c_1 \) and \( c_2 \) given in Eqs. (53) and (54), respectively, and \( \bar{q} \) denoting the complex conjugate of \( q \).

For the asymmetric XXZ chain, we have

\[
Z_E = \sum_{(r,m,p)} \exp\left(-\frac{e_1}{T} \sqrt{\frac{2\pi}{N}} \chi_j(r,m,p)\right).
\]

In this case, we can simply use the result of \( Z_F \) for \( M \) even by redefining the nome as

\[
q' = \exp(-\frac{e_1}{T} \sqrt{\frac{2\pi i}{N}})
\]

Using this, we then have

\[
Z_E = Z_1(q') \pm Z_2(q') + Z_3(q')
\]

where the + (−) sign is for \( N \) even (odd).

VI. SPECTRA AND PARTITION FUNCTIONS AT \( H = 0 \) AND \( V = V_C \)

The partition function of the isotropic lattice model on \( N \times M \) lattice should be invariant under rotation of the lattice by 90°. After the rotation, roles of \( H \) and \( V \) are also interchanged. Thus we expect an invariance of the partition functions under \( N \leftrightarrow M \) and \( H \leftrightarrow V \). When the system is in the critical phase, this symmetry is manifest by the
modular covariance of the partition function. Modular invariance plays an important role in classifying the conformal invariant theories and in revealing their mathematical structures. Present system is in a way a non-relativistic limit of the CFT and it is of interest to find the analog of the modular transformation. For this purpose, we have also calculated the energy spectra of the two models at $|H| \leq H_c$ for those which are low-lying near $V = V_c$ where $V_c$ is the $H$-dependent critical vertical field. The method employed is similar to the case of $H = H_c$ and $V = 0$ except that the ansatz for $Z_N^{-1}(\phi)$ takes a different form and that only those levels satisfying the condition Eq. (13) and $r \geq 0$ come into the working. Details of the derivations are given in Appendix [3]. To compare the result with that of the $V = 0$ phase boundary (the points A in Fig. 1), we consider only the $H = 0$ phase boundary (the points B in Fig. 1). Our result for the F model at $H = 0$ is

$$\Delta F = -\pi i m - 2r(V - H_c) + \frac{e_1^2}{2e_2} Y_4(r,m,p)(\pi/N)^2 + O(N^{-3})$$  \hspace{1cm} (70)$$

where $H_c$, $e_1$ and $e_2$ are given in Eqs. (12), (18) and (19), respectively, and $Y_4(r,m,p)$ is given by

$$Y_4(r,m,p) = \frac{8}{3} r^3 - \frac{2}{3} r + 2r m^2 - \sum_{k=1}^{n_r} \left( (2r - m + 1 - 2p_k)^2 - (2r - m - 1 + 2h_k)^2 \right) - \sum_{k=1}^{n_r} \left( (2r + m + 1 - 2\bar{p}_k)^2 - (2r + m - 1 + 2\bar{h}_k)^2 \right),$$

while that for the chain at $H = 0$ is

$$\Delta E = 2re_2 + \frac{e_4}{2e_2} Y_4(r,m,p)(\pi/N)^2 + O(N^{-3})$$  \hspace{1cm} (72)$$

where $e_4 \equiv -\Xi''(0) = \sum_{n=1}^{\infty} (-1)^{n+1} n^2 / \cosh n \lambda$. Note that $V_c$ at $H = 0$ is the same as $H_c$ for the lattice due to isotropy, but it is $e_2 = \Xi'(0)$ for the chain. For $H$ not equal to zero, imaginary $O(N^{-1})$ terms appear in $\Delta E$ and $\Delta F$. However, the real parts are $O(N^{-2})$ for all $|H| < H_c$.

From the result of the energy gaps, we are able to calculate the partition functions as in the previous section. We consider the lattice case first since it is more general. To compare with Eq. (23), we interchange $M$ and $N$ in Eq. (70) and offset the mass gap by setting $V = H_c$. Then the partition function of a $M \times N$ lattice at the phase boundary is

$$Z_F = \sum_{(r,m,p)} (-1)^{mN} \exp(-\frac{\pi}{\tau} Y_4(r,m,p))$$  \hspace{1cm} (73)$$

with $\tau = 2e_2^2 M^2 / (\pi e_2^2 N)$ as was given previously in Eq. (12). This quantity should be the same as that defined in Eq. (60) by symmetry. To express the partition function in a compact way, we define the new nome as

$$p = \exp(-\pi/\tau).$$  \hspace{1cm} (74)$$

This is analogous to the nome corresponding to the conjugate modulus in elliptic functions [1]. After performing the sums over the levels, we find $Z_F$ as

$$Z_F = \begin{cases} \tilde{Z}_1(p) \pm \tilde{Z}_2(p) + \tilde{Z}_3(p) & \text{for } M \text{ even} \\ \pm \tilde{Z}_1(p) + \tilde{Z}_2(p) \mp \tilde{Z}_3(p) & \text{for } M \text{ odd} \end{cases}$$  \hspace{1cm} (75)$$

where the upper (lower) sign is for $N$ even (odd) and $\tilde{Z}_i$ are defined as

$$\tilde{Z}_1(p) = \frac{1}{2} \prod_{j=-\infty}^{\infty} (1 + p^{1+2j})$$

$$\tilde{Z}_2(p) = \frac{1}{2} \prod_{j=-\infty}^{\infty} (1 + p^{4j^2})$$

$$\tilde{Z}_3(p) = \frac{1}{2} \prod_{j=-\infty}^{\infty} (1 - p^{1+2j}).$$  \hspace{1cm} (76), (77), (78)
Derivation of Eq. (73) is sketched in Appendix D. The corresponding partition function \( \tilde{Z}_E \) for the asymmetric XXZ chain with \( M \) sites at temperature \( T \) can be obtained from the \( N \) even result of Eq. (73) with \( p \) replaced by \( p' = \exp(-\epsilon_4 \pi^2/(2e^2 \pi^2 M^2 T)) \):

\[
\tilde{Z}_E = \tilde{Z}_1(p') \pm \tilde{Z}_3(p') + \tilde{Z}_2(p')
\]

(79)

with the + (−) sign for \( M \) even (odd).

Equating Eq. (63) and (73) for the 4 cases of parity of \( M \) and \( N \), we find

\[
Z_i(q) = \tilde{Z}_i(p)
\]

(80)

for all \( i = 1, 2, 3 \), and for any \( \tau \) where \( q \) and \( p \) are related to \( \tau \) by Eq. (63) and (73), respectively. This is an analog of the conjugate modulus transformation of the elliptic functions. These identities are obtained by calculating the physically same quantity in two independent ways and are confirmed numerically. However, we are not able to prove them directly. A byproduct of the identities is the analytic expression of \( c_1 \) mentioned below Eq. (64). Taking the \( \tau \to \infty \) limit in \( \ln \tilde{Z}_1(\exp(-\pi/\tau)) \), and evaluating the leading order contributions using Eq. (83), one easily obtains

\[
\ln \tilde{Z}_1(\exp(-\pi/\tau)) \longrightarrow \frac{1}{2}(\sqrt{2} - 1)\zeta(3/2)\sqrt{\tau/2}.
\]

(81)

Comparing this with \( Z_1(\exp(-\pi\sqrt{i\tau})) \), one obtains the alternate result for \( c_1 \) as

\[
c_1 = (\sqrt{2} - 1)\zeta(3/2)/(4\pi).
\]

(82)

Similar steps using \( \tilde{Z}_3(\exp(-\pi/\tau)) \) confirm the leading order behavior of \( Z_3(q) \) for small \( q \).

VII. DISCUSSIONS

In this paper, we have presented Bethe ansatz solutions for the finite-size corrections of the energy gaps at the antiferromagnetic phase transition for both the asymmetric XXZ chain and the isotropic 6-vertex model or the F model. Furthermore, all the low-lying levels are summed to obtain explicit expressions for partition functions. As a byproduct, interesting identities between several infinite products are found. Main results of this paper are Eqs. (63) and (64) for energy gaps at \( V = 0 \) phase boundary, Eqs. (72) and (70) for the same at \( H = 0 \) phase boundary, Eqs. (63) and (64) for the partition functions and the identities Eq. (80)

The finite-size corrections of the energy gaps are calculated using the method developed in I (73). Here, the phase function appearing in the Bethe ansatz solution is assumed to take certain form and is determined self-consistently. At \( H = H_c \) and \( V = 0 \), the finite-size corrections take the form of power series in \( N^{-1/2} \) because of the fact that the density of roots for the ground state vanishes at the end points of the root contour. The same is true on the stochastic line treated in I but, in the latter case, the leading \( O(N^{-1/2}) \) term is absent resulting in the \( N^{-3/2} \) scaling of energy gaps. For \( |H| < H_c \) and \( V = V_c \), the finite-size corrections come out as a power series in \( N^{-1} \). The leading \( O(N^{-1}) \) term is imaginary and the real contribution appears from \( O(N^{-2}) \). This \( N^{-2} \) scaling is the characteristic of the PT transition and is more generic. The points \( H = \pm H_c \) and \( V = 0 \) of the phase boundary are special in that the direction of the ‘time’ of the Hamiltonian Eq. (1) and the row-to-row transfer matrix of the lattice model is orthogonal to the direction of the field and tangential to the facet boundary in the \( H-V \) plane.

The partition function at \( H = 0 \) and \( V = V_c \) given in Eq. (63) is actually that of an one-dimensional non-relativistic free fermions with dispersion relation \( \varepsilon = Ak^2 \), \( A \) being a constant. To make exact correspondence with Eq. (63), we simply require the momenta \( k \) be even or odd integer multiple of \( \pi/L \), \( L \) being the length of the system, depending on the parity of the total number of fermions. Thus the effective theory on the \( H = 0 \) antiferromagnetic phase boundary is that of non-relativistic free fermions with the inverse temperature or the number of rows playing the role of imaginary time. This is also true at \( q = 0 \) or \( q = 1 \) (the dashed lines in Fig. 1) where the transition can be viewed as the PT-type commensurate-incommensurate transition [13, 24]. For such effective theory, the single particle wave function is \( \exp(ikx - ct) \) where \( t \) is the imaginary time. Now we consider the effect of rotation in \( x-t \) plane. Such transformation is not covered in the Schrödinger group [27] but makes sense in the context of lattice models. When the coordinates are rotated by an angle \( \theta \), in order for the wave function to remain invariant, the dispersion relation of the rotated system must change to \( \varepsilon' = ik' \tan \theta + A(\cos \theta)^{-1}k'^2 + O(k'^4) \) when \( \theta \neq \pm \pi/2 \) but to \( \varepsilon' = \sqrt{\pm ik'}/A \) when \( \theta = \pm \pi/2 \). Since the lattice model at \( H = H_c \) and \( V = 0 \) is obtained by rotating that at \( H = 0 \) and \( V = V_c \) by \( \pi/2 \), one naturally has excitations with \( \sqrt{\pm i}k' \) dispersion at the \( V = 0 \) phase boundary. From this, we can interpret the \( N^{-1/2} \) scaling at \( H = H_c \) and \( V = 0 \) as the feature arising from viewing the ordinary PT transition with space-time coordinate interchanged. However, the anomalies \( c_1 \) and \( c_2 \) in the rotated system are not explained by such simple effective theory.

APPENDIX A: RESURSION RELATION OF $J_{\pm}$

To show the recursion relation Eq. (A2), we introduce an auxiliary function defined for $\Re y > 0$ as

$$\tilde{J}(y) = \frac{1}{2i} \int_0^\infty \frac{\sqrt{y + it} - \sqrt{y - it}}{e^{\pi t} - 1} dt - \frac{1}{2} y^{1/2} + \frac{1}{3} y^{3/2}. \quad (A1)$$

$\tilde{J}(y)$ is related to $J_{\pm}(y)$ by $J_+(y) = \sqrt{-1} \tilde{J}(-iy)$ for $\Im y > 0$ and $J_-(y) = \sqrt{-1} \tilde{J}(iy)$ for $\Im y < 0$. Eq. (A2) follows from the recursion relation for $\tilde{J}(y)$ which is

$$\tilde{J}(y + 2) = \tilde{J}(y) + \sqrt{y} \quad (A2)$$

for $\Re y > 0$. To show Eq. (A2), we employ the general sum formula

$$\sum_{j=0}^n f(j) = \int_0^n f(x)dx + \frac{f(n) + f(0)}{2} + 2 \int_0^\infty \frac{\tilde{f}(n,t) - \tilde{f}(0,t)}{e^{2\pi t} - 1} dt \quad (A3)$$

where $\tilde{f}(x,t) = (f(x+it) - f(x-it))/2i$. This formula is valid if $f(x)$ is analytic and satisfies $\lim_{|t| \to \pm \infty} e^{-2\pi|t|} f(x+it) = 0$ in the strip $-\delta < \Re x < n + \delta$ for some $\delta > 0$. Applying Eq. (A3) to a trivial sum $\sum_{j=0}^1 \sqrt{y + 2j}$, one then obtains Eq. (A2).

APPENDIX B: PARTITION FUNCTION AT $H = H_0$ AND $V = 0$

In this appendix, we evaluate the partition function of the lattice model at the $V = 0$ phase boundary. That of the asymmetric XXZ chain follows simply redefining the nome and using the result of the lattice model for $M$ even. For simplicity, we consider the case of $M$ even and mention the other case at the end. Since $M$ is even, from Eq. (60), we are to evaluate

$$Z_F = \sum_{(r,m,p)} \exp(-\pi \sqrt{\tau} \gamma_{1}^{(r,m,p)}), \quad (B1)$$

where $\tau$ is given in Eq. (B2).

First consider the case $(2r + m)$ even. Further, if $m$ is in the range $-(2r + 1) < m \leq (2r + 1)$, $\gamma_{1}^{(r,m,0)}$ is given in Eq. (B1) and we have

$$\exp(-\pi \sqrt{\tau} \gamma_{1}^{(r,m,0)}) = (q\bar{q})^{-c_1} \prod_{j=0}^{r-m/2-1} q^{\sqrt{1+2j}} \prod_{j=0}^{r+m/2-1} q^{\sqrt{1+2j}} \quad (B2)$$

where $q = \exp(-\pi \sqrt{i\tau})$ and $\bar{q} = \exp(-\pi \sqrt{-i\tau})$. From Eq. (43), one notes that $\exp(-\pi \sqrt{\tau} \gamma_{1}^{(r,m,p)})$ is a product of $\exp(-\pi \sqrt{\tau} \gamma_{1}^{(r,m,0)})$ and factors coming from particle and hole excitations. A particle at position $p_k$ with $2p_k < (2r - m + 1)$ contributes a factor $\bar{q}^{\sqrt{1+2j}}$ where $j = r - m/2 - p_k = 0, 1, \ldots, (r - m/2 - 1)$, while that with $2p_k \geq (2r - m + 1)$ a factor $q^{\sqrt{1+2j}}$ where $j = p_k - r + m/2 - 1 = 0, 1, \ldots, \infty$. A hole at $h_k$ gives $q^{\sqrt{1+2j}}$ where $j = h_k - r - m/2 + 1 = r - m/2, r - m/2 + 1, \ldots, \infty$. Summing over all particle-hole configurations at the right-end of the Fermi sea corresponds to evaluating a free fermion grand-canonical partition function under the constraint that the total number of particles should be the same as that of holes. If we denote the fugacity of each particle (hole)
by \( z (z^{-1}) \), the desired sum is obtained by projecting out the \( z^0 \) term of the free fermion grand-canonical partition function which is

\[
\Xi_1(z) = \prod_{j=0}^{r-m/2-1} (1 + zq^{\sqrt{1+2j}}) \prod_{j=0}^{\infty} (1 + zq^{\sqrt{1+2j}}) \prod_{j=r-m/2}^{\infty} (1 + z^{-1}q^{\sqrt{1+2j}}),
\]

(B3)

\( \Xi_n(z) \) of this Appendix and Appendix D are not to be confused with \( \Xi(b) \) defined in Eq. (B9). We introduce a function \( A(z) \) by

\[
A(z) = \prod_{j=0}^{\infty} (1 + zq^{\sqrt{1+2j}}) \prod_{j=0}^{\infty} (1 + z^{-1}q^{\sqrt{1+2j}}),
\]

(B4)

and denote its Fourier coefficients by \( A_n; A(z) = \sum_n A_n z^n \). Then multiplying and dividing by a factor \( \prod_{j=0}^{r-m/2-1} (1 + z^{-1}q^{\sqrt{1+2j}}) \) on the right-hand side of Eq. (B3), we can put \( \Xi_1 \) in the form

\[
\Xi_1(z) = z^{r-m/2} A(z) \prod_{j=0}^{r-m/2-1} q^{-\sqrt{1+2j}}.
\]

(B5)

Thus the coefficient of \( z^0 \) of \( \Xi_1(z) \) is \( A_{r+m/2} \prod_{j=0}^{r-m/2-1} q^{-\sqrt{1+2j}} \). Note that the product over \( j \) in Eq. (B5) is cancelled by that in Eq. (B3). Summation over particle-hole configurations at the left-end of the Fermi sea proceeds in exactly the same way with \( m \) replaced by \(-m\) and \( q \) by \( \bar{q} \). Thus, the partition function after summation over all excitations from each \( m \)-shifted state is given as

\[
\sum_p \exp(-\pi\sqrt{r} \mathcal{Y}_1^{(r,m,p)}) = (q\bar{q})^{-c} A_{r+m/2} A_{-r-m/2}.
\]

(B6)

for \(-2(r+1) < m \leq 2(r+1)\) where \( A_n \) stands for the complex conjugate of \( A_n \). Similar calculations for each case of \( m > 2(r+1) \) and \( m \leq -(2r+1) \) show that Eq. (B6) holds for all \( m \), provided \( 2r+m \) is even. We then sum the right-hand side of Eq. (B6) over all even (odd) \( m \)'s for \( 2r \) even (odd). However, we note that \( \sum_m A_{-r+m/2} A_{r-m/2} \) is simply the coefficient of \( z^{-2r} \) in \( |A(z)|^2 \). To obtain the partition function in the \( 2r+m \) even sector, we finally sum over all integer (half integer) values of \( r \) if \( N \) is even (odd). Even though above derivations assumed \( r \geq 0 \), we may sum over negative \( r \)'s by the symmetry, \( |A(z)|^2 = |A(z^{-1})|^2 \). Since the sum over \( r \) is equivalent to summing over all coefficients of \( |A(z)|^2 \) and \( |A(z^{-1})|^2 \), it can be written as \( (A(1)^2 + A(-1)^2)/2 \) for \( N \) even (odd). Noting that \( (q\bar{q})^{-c} A(1)^2/2 = Z_1(q) \) and \( (q\bar{q})^{-c} A(-1)^2/2 = Z_2(q) \), we have the partition function in the \( 2r+m \) even sector as \( Z_1(q) \pm Z_2(q) \) with \(+\) (−) sign for \( N \) even (odd).

Next consider the case of \( 2(r+m) \) odd. If \( m \) is in the range \(-2(r+1) < m \leq 2(r+1)\), \( \mathcal{Y}_1^{(r,m,0)} \) is given in Eq. (B8) and we have

\[
\exp(-\pi\sqrt{r} \mathcal{Y}_1^{(r,m,0)}) = (q\bar{q})^{c_2} \prod_{j=0}^{r-(m+1)/2} \bar{q}^{-\sqrt{2j}} \prod_{j=0}^{r+(m-1)/2} q^{-\sqrt{2j}}.
\]

(B7)

A particle at position \( p_k \) with \( 2p_k \leq (2r - m + 1) \) contributes a factor \( \bar{q}^{-\sqrt{2j}} \) where \( j = r - (m-1)/2 - p_k \) = 0, 1, ..., \( r - (m+1)/2 \), while that with \( 2p_k > (2r - m + 1) \) a factor \( q^{\sqrt{2j}} \) where \( j = p_k - r - (m-1)/2 = 1, 2, ..., \infty \). A hole at \( h_k \) gives \( q^{\sqrt{2j}} \) where \( j = h_k + r - (m-1)/2 = r - (m-1)/2, r - (m-1)/2 + 1, \ldots \infty \). Thus the free fermion grand-canonical partition function for excitations at the right-hand side is

\[
\Xi_2(z) = \prod_{j=0}^{r-(m+1)/2} (1 + zq^{-\sqrt{2j}}) \prod_{j=1}^{\infty} (1 + zq^{\sqrt{2j}}) \prod_{j=r-(m-1)/2}^{\infty} (1 + z^{-1}q^{\sqrt{2j}}).
\]

(B8)

In line with the \( 2r+m \) even sector, we introduce a function \( B(z) \) by

\[
B(z) = \prod_{j=1}^{\infty} (1 + zq^{\sqrt{2j}}) \prod_{j=0}^{\infty} (1 + z^{-1}q^{\sqrt{2j}}),
\]

(B9)
and denote its Fourier coefficients by $B_n; B(z) = \sum_n B_n z^n$. Then $\Xi_2$ becomes

$$\Xi_2(z) = z^{r-(m-1)/2} B(z) \prod_{j=0}^{r-(m+1)/2} \bar{q}^{-\sqrt{2j}}$$

(B10)

and one sees that contribution from particle-hole excitations at the right-end is proportional to $B_{-r+(m-1)/2}$. Adding that of the left-end, we have the intermediate partition function as

$$\sum_{\ell} \exp(-\pi \sqrt{2} y_1^{(r,m,\ell)}) = (q\bar{q})^{r/2} B_{-r+(m-1)/2} \tilde{B}_{-r-(m+1)/2}$$

(B11)

for $-2(r+1) < m \leq (2r+1)$ and $(2r+m)$ odd. Similar calculations for each case of $m > (2r+1)$ and $m \leq -(2r+1)$ again show that Eq. (B11) holds for all $m$ provided $(2r+m)$ is odd. Proceeding as above, we sum over $m$ and $r$ in Eq. (B11) using the symmetry $z[B(z)]^2 = z^{-1}[B(z^{-1})]^2$ and finally find the partition function in $(2r+m)$ odd sector as $(q\bar{q})^{r/2} (B(1)^2 + B(-1)^2)/2$ for $2r$ even and $(q\bar{q})^{r/2} (B(1)^2 - B(-1)^2)/2$ for $2r$ even. But $B(-1) = 0$ so that it becomes $(q\bar{q})^{r/2} B(1)^2/2 = Z_\delta(q)$ for both parity of $N$. Adding this to that of $(2r + m)$ even sector, we have Eq. (B3) for $M$ even.

When $M$ is odd, we need to insert a factor $(-1)^m$ to Eqs. (B4) and (B11). This does not complicate the sums since the sums over $m$ in each sector are in steps of 2 and the sign factor is equivalent to $(-1)^{2r}$ for the case of Eq. (B4) and $(-1)^{2r+1}$ for the case of Eq. (B11). These extra sign factors then give the full partition function as given in Eq. (B3) for $M$ odd.

**APPENDIX C: SPECTRA AT $H = 0$ AND $V = V_C$**

In this section, we derive $\Delta E$ and $\Delta F$ at the phase boundary of $H = 0$. Although our main interest is for $H = 0$, discussions up to Eqs. (112) and (114) hold for general $0 \leq H < H_c$.

When $|H| < H_c$, $Z_\infty$ given by Eq. (17) has non-vanishing first derivative at $x_0 \equiv \exp(\pi i + \lambda - b)$, the end point of the root distribution in bulk limit, which is related to $H$ by Eq. (20). Thus our starting ansatz for $Z_N^{-1}(x)$ is, instead of Eq. (20),

$$Z_N^{-1}(\pm \pi q + \pi \xi/N) = x_0^+ + a_2 \pi (y_\pm - i \xi)/N + a_4 \pi^2 (y_\pm - i \xi)^2/N^2 + \cdots$$

(C1)

where $x_0^+ = x_0$ and $x_0^- = x_0 e^{-2\pi i}$. Here, $y_\pm$, $a_2$ and $a_4$ are to be determined self-consistently. We then follow the same line of steps as in Section III. However, as we have seen in Section IV, the levels not satisfying the condition Eq. (12) become higher in energy by $O(1)$ than those which do. This is because the roots of the Bethe ansatz equation, $x_j$ or $x_{Q-j}$, for $j$ finite, may not remain close to $x_0^\pm$. So, Eq. (C1) is useless only to the levels which do satisfy Eq. (12). Repeating the algebra, the sum Eq. (27) is then found to take the form

$$S[f] = \frac{N}{2\pi i} \int f(x) R_N(x) \frac{dx}{x} = (m + iy_+)/2 f(x_0^+) - (m + iy_-)/2 f(x_0^-)$$

$$+ f'(x_0) \Phi + f''(x_0) \Psi + O(N^{-3})$$

(C2)

where $\Phi$ and $\Psi$ are short notations for

$$\Phi = a_2 \pi Y_2(y_+, y_-)/N + a_4 \pi^2 Y_4(y_+, y_-)/N^2,$$

(C3)

$$\Psi = \frac{1}{2} a_2^2 \pi^2 Y_4(y_+, y_-)/N^2$$

(C4)

with

$$Y_{2n}(y_+, y_-) = -i J_+^{(n)}(y_+ + i - 2m_i) + i J_-^{(n)}(y_- - i - 2m_i)$$

$$+ \sum_{k=1}^{n_+} \left\{ (y_+ + i(1 - 2m - 2\tilde{p}_k))^n - (y_+ - i(1 + 2m - 2\tilde{h}_k))^n \right\}$$

$$+ \sum_{k=1}^{n_-} \left\{ (y_- - i(1 + 2m - 2\tilde{h}_k))^n - (y_- + i(1 - 2m - 2\tilde{p}_k))^n \right\}.$$  

(C5)
Applying Eq. (C2) with Eqs. (C7) and (C11) to Eqs. (5) and (8), we then obtain after some algebra,

$$x_n$$

for the lattice model where

$$O_g = 0$$

implies that the critical field

$$O_o = 0$$

when

$$O_o = 0$$

and the self-consistency equations for

$$y_+$$, $$a_2$$ and $$a_4$$ as

$$\pm i\pi q + y_+ \frac{\pi}{N} = \pm i(1-q)\pi + 2H - \lambda + 2 \sum_{n \neq 0} \frac{\alpha^n}{1 + \alpha^n} \frac{x_0^n}{n}$$

$$+(1 + \frac{2r}{N} - \frac{y_+ - y_-}{2Ni}) \ln |x_0| + (2im - \frac{y_+ + y_-}{2}) \frac{\pi}{N}$$

$$+ 2e_0x_0^{-1}(\Phi - \Psi/x_0)N^{-1} + O(N^{-4}),$$

$$- a_2^{-1} = iZ_{\infty}'(x_0) + 2re_0x_0^{-1}N^{-1} + O(N^{-3}),$$

$$2a_4a_2^{-3} = iZ_{\infty}''(x_0) + O(N^{-1})$$

where $Z_{\infty}(x)$ is given in Eq. (17) and $y_+ - y_- = 4ir$ which follows from Eq. (C8) has been used in Eq. (C9). From Eq. (C8), one gets, after using Eq. (18),

$$y_\pm = (\pm 2r + m)i + \pi^{-1}e_0(\Phi/x_0 - \Psi/x_0^2) + O(N^{-3}).$$

Applying Eq. (C2) with Eqs. (C7) and (C11) to Eqs. (3) and (8), we then obtain after some algebra,

$$\Delta E = 2r\Xi'(b) + \Xi''(b)(x_0^{-1}\Phi - x_0^{-2}\Psi) - \Xi'''(b)x_0^{-2}\Psi + O(N^{-3})$$

for the chain and

$$\Delta F = -\pi im - 2r(V - \Xi(\lambda - b)) - \Xi'(\lambda - b)(x_0^{-1}\Phi - x_0^{-2}\Psi) - \Xi''(\lambda - b)x_0^{-2}\Psi + O(N^{-3})$$

for the lattice model where $x_0 = -\exp(\lambda - b)$ and $\Xi(b)$ is defined in Eq. (21). The $O(1)$ terms in Eqs. (C12) and (C13) imply that the critical field $V_C$ as a function of $H$ is given by $\Xi(b)$ for the chain and by $\Xi(\lambda - b)$ for the lattice. These $O(1)$ terms are offset by the vertical field at the phase boundary. Eqs. (C12) and (C13) contain, through $\Phi$, an $O(N^{-1})$ term proportional to $Y_2(y_\pm = \pm 2ri + mi)$ which is purely imaginary. Thus the real parts of the energy gaps at the antiferromagnetic phase boundary are $O(N^{-2}).$

Up to here $H$ is general. For simplicity, we now specialize to $H = 0$ at corresponding values of the critical vertical field. When $H = 0, x_0 = -e^\lambda, b = 0$ and $a_2 = e^\lambda/e_2 + O(N^{-1}).$ Setting $b = 0$ in Eqs. (C12) and (C13), one notes that the imaginary $O(N^{-1})$ terms all vanish simplifying the results considerably. Final expression for $\Delta E$ and $\Delta F$ then becomes as given in Eqs. (72) and (74), respectively, where $Y_4(r,m,p)$ is the value of $Y_4(y_+, y_-)$ evaluated at the zeroth order solution for $y_\pm$, i.e. $Y_4(y_\pm = i(\pm 2r + m)).$

**APPENDIX D: PARTITION FUNCTIONS AT $H = 0$ AND $V = V_C$**

In this Appendix, we derive Eq. (74). Consider the lattice model on $M \times N$ lattice with $M$ and $N$ even. Then from Eqs. (73) and (74), we have

$$Z_F = \sum_{(r,m,p)} p^{2r, m, p}$$

with $p^{2r, m, p}$ given in Eq. (71) and the sum is for $r = 0, 1, \ldots$ under the restriction Eq. (79). Considering first $(2r + m)$ even sector, from Eq. (71), one sees that a particle (hole) at position $p_k$ ($h_k$) contributes $p^{-(1+2j)^2} (p^{1+2j})^2$ with
0 \leq j \leq r - m/2 - 1 \ (j \geq r - m/2). Thus the free fermion grand-canonical partition function for the right-hand side excitation is

\[ \Xi_3(z) = \prod_{j=0}^{r-m/2-1} (1 + zp^{-(1+2j)^2}) \prod_{j=r-m/2}^{\infty} (1 + z^{-1}p^{(1+2j)^2}) \]

\[ = z^{r-m/2} C(z) \prod_{j=0}^{r-m/2-1} p^{-j^2} \]  

where

\[ C(z) = \prod_{j=0}^{\infty} (1 + z^{-1}p^{(1+2j)^2}) = \sum_{n=0}^{\infty} C_n z^{-n}. \]  

Thus the coefficient of \( z^0 \) in \( \Xi_3(z) \) can be written as \( C_{r-m/2} \prod_{j=0}^{r-m/2-1} p^{-(1+2j)^2} \). The left-hand side excitations give the same result with \( m \to -m \). Using the fact that \( \sum_{j=0}^{r-m/2-1} (1+2j)^2 + \sum_{j=0}^{r+m/2-1} (1+2j)^2 = 8r^3/3 - 2r/3 + 2rm^2 \), we note that the product in the second line of Eq. (D2) is cancelled by that coming from the first terms of \( \gamma_4(r.m,p) \). Thus we have

\[ \sum_p \gamma_4(r.m,p) = C_{r-m/2} C_{r+m/2}. \]  

Summing Eq. (D4) over \( m \) from \(-2r \) to \(+2r \) in steps of 2 and over \( r \geq 0 \), we find the partition function in the \((2r+m)\) even sector as \( (C(1)^2 + C(-1)^2)/2 = \Xi_3(p) \).

Next consider the \((2r+m)\) odd sector. In this case the free fermion grand-canonical partition function for the right-hand side excitations is

\[ \Xi_4(z) = \prod_{j=1}^{r-(m+1)/2} (1 + zp^{-4j^2}) \prod_{j=r-(m-1)/2}^{\infty} (1 + z^{-1}p^{4j^2}) \]  

while that for the left-hand side is

\[ \tilde{\Xi}_4(z) = \prod_{j=1}^{r+(m+1)/2} (1 + zp^{-4j^2}) \prod_{j=r+(m-1)/2}^{\infty} (1 + z^{-1}p^{4j^2}). \]  

Note that the \( j = 0 \) term is excluded in Eq. (D6) due to the strict inequality in Eq. (D3). Defining

\[ D(z) = \prod_{j=0}^{\infty} (1 + z^{-1}p^{4j^2}) = \sum_{n=0}^{\infty} D_n z^{-n} \]  

\[ \tilde{D}(z) = \prod_{j=1}^{\infty} (1 + z^{-1}p^{4j^2}) = \sum_{n=0}^{\infty} \tilde{D}_n z^{-n} \]  

we can write

\[ \sum_p \gamma_4(r.m,p) = D_{r-(m-1)/2} \tilde{D}_{r+(m-1)/2} \]  

where \( \sum_{j=0}^{r-m/2-1/2} (2j)^2 + \sum_{j=1}^{r+m/2-1/2} (2j)^2 = 8r^3/3 - 2r/3 + 2rm^2 \) has been used. We then sum Eq. (D9) over \( m \) from \(-2r+1 \) to \(2r+1 \) in steps of 2 and finally over \( r \geq 0 \) to obtain the remaining piece of the partition function as \( (D(1)\tilde{D}(1) + D(-1)\tilde{D}(-1))/2 = \Xi_3(p) \). We thus arrive at Eq. (D3) for \( M \) and \( N \) even. For other parities of \( M \) and \( N \), we repeat above steps with only minor changes and find Eq. (D3).

FIG. 1. (a) Phase diagram in fields of the asymmetric XXZ chain for $\lambda = 2.5$. The solid curve is the antiferromagnetic phase boundary and the dashed ones are the ferromagnetic phase boundary. The region between the curves is the critical phase. The point A (B) is the $H = H_c, V = 0$ ($H = 0, V = V_c$) phase boundary discussed in Section V (VI). (b) The same as in (a) for the isotropic 6-vertex model (F-model).

FIG. 2. Examples of energy levels for $N = 20$ and $Q = 10$ ($r = 0$). Filled circles denotes integers included in $\{I_j\}$. (a) The ground state (0,0,0) (b) The 1-shifted level (0,1,0) (c) An excited level from (b) which has two particle-hole pairs at the right-end of the Fermi sea (with positions $p_1=2, p_2=3, h_1=1$ and $h_2=2$) and one particle-hole pair at the left-end (with $\tilde{p}_1=1$ and $\tilde{h}_1=1$).
