(Dated: August 25, 2007)

We propose a lower bound on bulk viscosity of strongly coupled gauge theory plasmas. Using explicit example of the $\mathcal{N} = 2^*$ gauge theory plasma we show that the bulk viscosity remains finite at a critical point with a divergent specific heat. We present an estimate for the bulk viscosity of QGP plasma at RHIC.

PACS numbers: 11.25.Tq, 47.17.+e

Recently, a holographic link between finite temperature gauge theories and string theory black holes emerged [1, 2, 3, 4]. While the precise holographic dual to QCD is still missing, a progress in study of string theory black holes made it possible to compare the thermodynamics of strongly coupled QCD-like gauge theories [5, 6] with lattice results [7]. The dual holographic approach has been successful to address dynamical properties of QGP such as the shear viscosity [8] and the parton jet quenching [9, 10], where few alternative techniques are available. Intriguingly, dual string theory studies reveal certain universal features of gauge theory plasma dynamics. A notable examples is the ratio of the shear viscosity $\eta$ to the entropy density $s$. It was shown in [11, 12, 13, 14] that

$$\frac{\eta}{s} = \frac{1}{4\pi} \rightarrow \frac{\hbar}{4\pi k_B} \approx 6.08 \times 10^{-13} \text{ K s},$$

(1)

in any gauge theory plasma at infinite ’t Hooft coupling, irrespectively of the dimensionality of the space, the microscopic scales of the theory, and chemical potentials for the conserved quantities. The universality of the shear viscosity ratio [11] in strongly coupled gauge theories at finite temperature led Kovtun, Son and Starinets (KSS) to conjecture a shear viscosity bound [15]

$$\frac{\eta}{s} \geq \frac{1}{4\pi},$$

(2)

for all physical systems in Nature. Empirically, the KSS bound indeed appears to be satisfied by all common substances [12]; moreover, it is correct at large (but finite) ’t Hooft coupling in $\mathcal{N} = 4$ Yang-Mills theory plasma [16, 17].

We believe that it is such universal features of dual holographic models of gauge theories that might have some relevance to QCD. Thus, it is imperative to ask what are other generic properties of strongly coupled gauge theories. The question is complicated as neither the bulk viscosity [18] nor the quenching of parton jets [19] is universal for different gauge theory plasmas.

It this Letter we propose a lower bound on bulk viscosity $\zeta$ of strongly coupled gauge theories. Based on holographically dual computations, we conjecture that a bulk viscosity in a strongly coupled gauge theory plasma in $p$-space dimensions satisfies

$$\frac{\zeta}{\eta} \geq 2 \left( \frac{1}{p} - c_s^2 \right),$$

(3)

where $c_s$ is the speed of sound. Notice that unlike the shear viscosity bound (2), our bound (3) is dynamical: as the temperature varies, generically both the speed of sound and the ratio of bulk-to-shear viscosities will change. Our claim is that the bound (3) is correct over all range of temperatures.

In the following we present evidence in support of the bulk viscosity bound (3). First, we observe that the bound is saturated by the $p + 1$ space-time dimensional gauge theory plasma holographically dual to a stack of near-extremal flat D$p$-branes [20], as well as in the hydrodynamics of Little String Theory [20, 21]. Second, we point out that the bound (3) remains saturated once above $p$-space dimensional gauge theory plasma is compactified on a $k < p$ space-dimensional torus [20, 22]. Third, we observe that the bound is satisfied (but in general not saturated) in certain $3 + 1$ strongly coupled non-conformal plasma at high temperature [18, 23]. Finally, we present results [24] for the bulk viscosity of the $\mathcal{N} = 2^*$ gauge theory plasma [5, 22, 26, 24, 28, 29] over a wide range of temperatures, and for various mass deformation parameters. We find that the bulk viscosity of the $\mathcal{N} = 2^*$ plasma satisfies the bound (3). As observed in [5], the $\mathcal{N} = 2^*$ plasma with zero fermion masses undergoes an interesting phase transition with vanishing speed of sound. A detailed analysis of the critical point [24] reveals that at the transition point the specific heat diverges as $c_V \sim |1 - T_c/T|^{-1/2}$. We find that despite the divergent specific heat the bulk viscosity at criticality re-
mains finite. We use results for the $\mathcal{N} = 2^*$ gauge theory plasma to estimate the bulk viscosity of QGP at RHIC.

**Bulk viscosity of Dp-brane gauge theory plasma.** $\mathcal{N} = 4$ Yang-Mills plasma at strong coupling is holographically dual to near-extremal stack of D3 branes. In this case conformal invariance of the theory implies that

$$c_s^2 = \frac{1}{3}, \quad \zeta = 0. \quad (4)$$

Eq. (4) was verified in supergravity approximation in $[30]$ and beyond the supergravity approximation in $[17]$. Notice that $\mathcal{N} = 4$ plasma trivially satisfies the bound $[33]$. In $[20]$ the authors generalized computation of $[30]$ to $p+1$ space-time dimensional gauge theory plasma holographically dual to near-extremal stack of Dp branes. They found the following dispersion relation for the sound waves

$$\omega = \sqrt{\frac{5-p}{9-p}} q - i \frac{2}{9-p} q^2 + \cdots , \quad (5)$$

where

$$w = \frac{\omega}{2\pi T}, \quad q = \frac{q}{2\pi T}. \quad (6)$$

Hydrodynamics of a fluid with shear and bulk viscosities $\{\eta, \xi\}$ in $p$-space dimensions predicts the following sound wave dispersion

$$\omega = c_s q - i \frac{\eta}{sT} \left( \frac{p-1}{p} + \frac{\zeta}{2\eta} \right) q^2 + \cdots . \quad (7)$$

Using the universality of the shear viscosity $[11]$, one can verify that the bound $[33]$ is saturated $[20]$ in the hydrodynamics of the flat Dp branes. It is saturated as well in the hydrodynamics of Little String Theory $[20, 21]$.

We point out now that the bound $[33]$ is saturated as well for above strongly coupled gauge theory plasmas compactified on a $k$-dimensional torus ($k < p$) $[32]$. Indeed, upon such a compactification the dispersion relation $[7]$ will not change — much like an equation of state it is sensitive only to the local properties of the background geometry:

$$w_{k<p} = \sqrt{\frac{5-p}{9-p}} q - i \frac{2}{9-p} q^2 + \cdots . \quad (8)$$

On the other hand, the hydrodynamics relation $[7]$ is sensitive to the number of macroscopic (infinitely extended) directions:

$$\omega_{k<p} = c_s q - i \frac{\eta_{k<p}}{s_{k<p} T} \left( \frac{p-k}{p-k} - \frac{1}{2\eta_{k<p}} \right) q^2 + \cdots . \quad (9)$$

Again, using the universality of the shear viscosity $[11]$ we find (see also Eq. (5.2) of Ref. $[20]$)

$$\frac{\zeta_{k<p}}{\eta_{k<p}} = 2 \left( \frac{1}{p-k} - c_s^2 \right) . \quad (10)$$

It is precisely for the stated reason the bound $[33]$ is saturated in Sakai-Sugimoto model in the quenched approximation $[22]$, even though

$$\frac{\zeta}{\eta}_{\text{Sakai–Sugimoto}} = \frac{4}{15} \neq \frac{1}{10} = \frac{\zeta}{\eta}_{D4} . \quad (11)$$

**Bulk viscosity of non-conformal plasma at high temperatures.** A much more nontrivial example is the bulk viscosity of non-conformal gauge theory plasma in four dimensions. The computation in the cascading gauge theory $[31, 33]$ produced $[23]$

$$\frac{\zeta}{\eta}_{\text{cascading}} = 2 \left( \frac{1}{3} - c_s^2 \right) + \mathcal{O} \left( \left[ \frac{1}{3} - c_s^2 \right]^2 \sim \ln^{-2} \frac{T}{\Lambda} \right), \quad (12)$$

where $\Lambda$ is the strong coupling scale of the cascading gauge theory.

Likewise, for $\mathcal{N} = 2^*$ gauge theory plasma with bosonic and fermionic mass deformation parameters $m_b \ll T$ and $m_f \ll T$,

$$\frac{\zeta}{\eta}_{m_f=0} = \frac{\beta_f^*}{16} \left( \frac{1}{3} - c_s^2 \right) + \mathcal{O} \left( \left[ \frac{1}{3} - c_s^2 \right]^2 \right), \quad (13)$$

where $\beta_f^* \approx 0.66666$ $[34]$.

In all cases above we find that the viscosity bound $[33]$ remains true — in general, it is no longer saturated.

**Bulk viscosity of $\mathcal{N} = 2^*$ plasma.** The strongest support for the bulk viscosity bound $[33]$ comes from study of the $\mathcal{N} = 2^*$ bulk viscosity over the wide range of temperatures. Such analysis is a direct extension of the framework presented in $[18]$. The computations are extremely technical and will be detailed elsewhere $[24]$. Here, we report only the results of the analysis $[35]$. Fig. $[1]$ represents the ratio $\frac{c_s}{c}$ versus the speed of sound in $\mathcal{N} = 2^*$ gauge theory plasma with $m_f = 0$. This model reaches a critical point with vanishing speed of sound at $\frac{T}{\Lambda} \approx 2.32591$ $[3]$. Although near the critical point the specific heat diverges as $c_V \sim \left| 1 - T_c/T \right|^{-1/2}$ $[24]$ (also
Estimates for the viscosity of QGP at RHIC. It is tempting to use the $\mathcal{N} = 2^*$ strongly coupled gauge theory plasma results to estimate the bulk viscosity of QGP produced at RHIC. For $c_s^2$ in the range $0.27 - 0.31$, as in QCD at $T = 1.5 T_{deconfinement}$ [36, 37], we find

$$\frac{\zeta}{\eta} \bigg|_{m_f = 0} \approx 0.17 - 0.61, \quad \frac{\zeta}{\eta} \bigg|_{m_b = m_f = m} \approx 0.07 - 0.15.$$  

(15)

Since RHIC produces QGP close to its criticality, we believe that $m_f = 0$ $\mathcal{N} = 2^*$ gauge theory model would reflect physics more accurately. If so, it is important to reanalyze the hydrodynamics models of QGP with nonzero bulk viscosity in the range given by (15).

In this Letter we presented some evidence in support of the bulk viscosity bound in strongly coupled gauge theory plasmas. It would be interesting to examine other holographic models and test the bound. As in [12], it would be interesting to study applicability of the bound in common substances realized in Nature. It appears that common liquids, like water, satisfy the bound [38]. While the bound is generically satisfied in polyatomic gases [39], it is violated in monoatomic gases [40]. The bound also appears to be violated in high-temperature...
QCD at weak coupling [41]. In fact, experimental study of the bulk viscosity in argon at different densities [42] demonstrates that its ratio of bulk-to-shear viscosities violates/satisfies the bound at small/large densities. All this indicates the relevance of the bulk viscosity bound [3] to strongly coupled systems only.

We demonstrated that the bulk viscosity in the $\mathcal{N} = 2^*$ plasma with vanishing fermionic masses has a finite viscosity at the critical point with divergent specific heat. The corresponding critical exponent $\alpha = 0.5 \ (c_v \sim [1 - T_c/T]^{-\alpha})$ coincides with the mean-field universal value at the tricritical point [43]. Such a tricritical point is realized experimentally in solids [44]. It would be interesting to find a fluid with such a universal tricritical point and compare its bulk viscosity with that of the $\mathcal{N} = 2^*$ plasma at criticality.

I would like to thank Colin Denniston, Javier Mas, Rob Myers, Chris Pagnutti, Jim Sethna and Andrei Starinets for valuable discussions. My research at Perimeter Institute is supported in part by the Government of Canada through NSERC and by the Province of Ontario through MEDT. I gratefully acknowledges further support by an NSERC Discovery grant.

[34] There is a mistake in Eq. (4.37) in [18]: correspondingly to the connection coefficient of $dZ^\alpha / dx$ in Eq. (4.35), the connection coefficient of $dZ^\beta / dx$ in Eq. (4.37) must be $12x^2 (x^2 - 1)^2$. Fixing this mistake leads to the value of $\beta^1$ presented [24].
