RESEARCH ARTICLE

Phosphorylated Akt Protein at Ser473 Enables HeLa Cells to Tolerate Nutrient-Deprived Conditions

Moustafa Fathy¹,², Suresh Awale³, Toshio Nikaido¹*

Abstract

Background: Despite angiogenesis, many tumours remain hypovascular and starved of nutrients while continuing to grow rapidly. The specific biochemical mechanisms associated with starvation resistance, austerity, may be new biological characters of cancer that are critical for cancer progression. Objective: This study aim was to investigate the effect of nutrient starvation on HeLa cells and the possible mechanism by which the cells are able to tolerate nutrient-deprived conditions. Methods: Nutrient starvation was achieved by culturing HeLa cells in nutrient-deprived medium (NDM) and cell survival was estimated by using cell counting kit-8. The effect of starvation on cell cycle distribution and the quantitative analysis of apoptotic cells were investigated by flow cytometry using propidium iodide staining. Western blotting was used to detect the expression levels of Akt and phosphorylated Akt at Ser473 (Ser⁴⁷³p‐Akt) proteins. Results: HeLa cells displayed extremely long survival when cultured in NDM. The percentage of apoptotic HeLa cells was significantly increased by starvation in a time-dependent manner. A significant increase in the expression of Ser⁴⁷³p‐Akt protein after starvation was also observed. Furthermore, it was found that Akt inhibitor III molecule inhibited the cells proliferation in a concentration- and time-dependent manner. Conclusion: Results of the present study provide evidence that Akt activation may be implicated in the tolerance of HeLa cells for nutrient starvation and may help to suggest new therapeutic strategies designed to prevent austerity of cervical cancer cells through inhibition of Akt activation.

Keywords: HeLa cells- starvation- austerity- Akt-Akt inhibitor III molecule

Introduction

Rapidly growing solid tumours are often inherently hypovascular, thus exhibiting reduced oxygen and nutrient supply (Sutherland, 1988; Vaupel et al., 1989). Rather than impeding cancer progression, such poor metabolic conditions can contribute to genomic instability, impaired cellular repair, mutagenesis, and resistance to chemotherapy, thus worsening prognoses for patients (Yun et al., 1995; Reynolds et al., 1996; Tomida et al., 1996; Yuan et al., 2000). These rapidly growing tumour cells outgrow their blood supply resulting in a reduced nutrients microenvironment. Tumour cells by altering metabolic strategies and inducing angiogenesis can adapt to this stressful environment, thus ensuring survival and proliferation (Izuishi et al., 2000; Awale et al., 2006; Awale et al., 2008; Wek and Staschke, 2010; Calastretti et al., 2014; Jones et al., 2014; Md Tohid et al., 2014; Kim et al., 2015; Farley et al., 2016). Therefore, angiogenesis is regarded as the key step in progression of tumor, and antiangiogenic therapy is the most promising cancer treatment, with extensive studies conducted to prevent tumor angiogenesis (Bergers et al., 1999).

Despite considerable evidence of angiogenesis (Fisher and Berger, 2003; Fleming and Brekken, 2003; Thorpe, 2004; Masamune et al., 2008), many tumours remain hypovascular, and starved of nutrients while continuing to grow rapidly. The therapeutic strategies of angiogenesis inhibition and vascular targeting (Richard et al., 1999; Thorpe, 2004) endeavour to kill tumour cells by selectively depriving them of nutrients. In this light, aggressive tumours, that thrive despite being chronically nutrient-deprived, present a serious therapeutic challenge.

It is well known that tumor cells have high glycolytic activity (Dang and Semenza, 1999). This is because the multiple steps of carcinogenesis expose the tumor cells to insufficient nutrient supply because of increasing demand and insufficient vascularization. Even after the size of tumor increases, the cancer cells’ immediate environment often becomes heterogeneous. In addition, microenvironmental niches often present in some regions of large tumors, displaying a significant gradient of critical metabolites including oxygen, glucose, other nutrients, and growth factors (Helmlinger et al., 1997; Dang and

HeLa Cells Austerity Through Ser⁴⁷³p-Akt
Because normal tissues are rarely exposed to extreme nutrient-deprived conditions or not. These conditions may acquire a tolerance for nutrient deficiency (Calastretti et al., 2014; Jones et al., 2014; Farley et al., 2016).

Since its discovery, the phosphoinositol-3-kinase (PI3K)-Akt pathway has been found to have key regulatory roles in many cellular processes, including proliferation, cell survival and differentiation (Wymann and Marone, 2005). PI3Ks are heterodimeric lipid kinases composed of catalytic and regulatory subunits. The main function of PI3Ks is to phosphorylate the second messenger phosphotyidylinositol-4,5-bisphosphate (P1-4,5-P2) to phosphotyidylinositol-3,4,5-trisphosphate (P1-3,4,5-P3). Through this enzymatic function, PI3K signaling pathway plays an important role in regulating cell responses to external stimuli. Accordingly, PI3K and signaling regulated by PI3K has been targets of therapeutic strategies for a wide range of diseases (Van Meter et al., 2006).

Akt is involved in the pathways responsible for cellular survival through the inhibition of apoptotic processes. It can induce protein synthesis pathways, so it is considered as a key signaling protein in the cellular pathways that lead to general tissue growth. Since it can promote cell survival, Akt has been implicated in many types of cancer as a major factor. It plays a role in the cell cycle and regulates cellular survival by regulating many effectors, e.g. Nuclear Factor-kappa B (NFkB). Under various circumstances, cell cycle arrest can be overcome by the activation of Akt. Moreover, Akt has also been implicated in tumor development and angiogenesis. Although deficiency of Akt in mice inhibited angiogenesis, its activation enhanced tumor growth and pathological angiogenesis associated with matrix abnormalities in blood vessels and skin (Soroceanu et al., 2007). High expression of Akt was demonstrated in the metabolic adaptation of pancreatic, gastric and colorectal cancer cells subjected to extreme nutrient deprivation (Calastretti et al., 2014; Jones et al., 2014).

Affecting women worldwide, cervical cancer is the fourth most common malignancy. In developing countries, it remains a leading cause of cancer-related death for women (Forouzanfar et al., 2011; Siegel et al., 2016). In this study, HeLa cells, human cervical carcinoma cells, were examined if they are able to survive even under complete nutrient deficiency conditions or not. These investigations raise the possibility that, in addition to angiogenesis, the tolerance for nutrient deficiency might be critical for cancer progression and a new biological character of cancer. Recent advances in identification of molecular signals that mediate the tolerance of cancer cells to nutrient deprived conditions are necessary for the development of new anticancer strategies. In addition, because normal tissues are rarely exposed to extreme deficiency of nutrients, tolerance for nutrient deprived conditions might serve as a new goal for anticancer drugs.

Materials and Methods

Cell lines and nutrient starvation

HeLa cells, obtained from the American Type Culture Collection (ATCC, Manassas, VA, USA), were maintained in fresh Dulbecco’s Modified Eagle’s Medium (DMEM, Sigma-Aldrich Co., St Louis, MO, USA) supplemented with 10% Fetal Bovine Serum (FBS, Biosolutions International, Melbourne, Australia), 1% L-glutamine (Sigma-Aldrich Co.), and 1% Penicillin-Streptomycin mixture (Invitrogen, Grand Island, NY, USA). Nutrient starvation was achieved by using NDM which was prepared following the method of Kim et al., (2015).

NDM was composed of 265 mg/L CaCl2·(2H2O), 0.1 mg/L Fe(NO3)3·(9H2O), 400 mg/L KCl, 200 mg/L MgSO4·(7H2O), 6400 mg/L NaCl, 3500 mg/L NaHCO3, 125 mg/L NaH2PO4, 15 mg/L phenol red, and 25 mmol/L HEPES buffer (pH 7.4), supplemented with MEM vitamin solution (Life Technologies. Rockville, MD, USA). Cells were plated on microplates or culture dishes using either of both media and incubated at 37 °C in a 5% CO2 humidified incubator.

Cell viability assay

Cell viability assay was done with cell counting kit-8 from Dojindo Molecular Technologies (Dojindo Co., Kumamoto, Japan). Briefly, the cells were seeded in sextuplicate at a density of 5×104 cells per well in 96-well plates and allowed to grow in fresh DMEM medium for 24 h. The cells were then washed with Phosphate Buffered Saline (PBS, pH = 7.4, Sigma-Aldrich, Inc) and the medium was changed to either DMEM or NDM. After the specified time of incubation, the cells were washed again with PBS, then 100 µL of DMEM medium with 10% WST-8 (2-(2-methoxy-4-nitrophenyl)-3-(4-nitrophenyl)-5-(2,4-disulfophenyl)-2H-tetrazolium) solution was added to the wells, and the plate was incubated for a further 2 hours. Then, the absorbance of the wells at 450 nm was measured using HTS Multi-Mode Microplate Reader (BioTek Instruments, Winooski, VT). The absorbance is proportional to the number of viable cells in the medium. Cell viability at different time points was expressed as percentage relative to that at the start of starvation (0 hr) which is considered as 100%.

Assessment of cell cycle and apoptosis by flow cytometry

The cells were seeded in triplicate at a density of 2×104 cells per well in 6-well plates and allowed to grow in fresh DMEM medium for 24 h. The cells were then washed with PBS and the medium was changed to either DMEM or NDM. The protocol for the flow cytometric analysis of cell cycle distributions using propidium iodide was used (Sophonithiprasert et al., 2017). At different time points (24 hr, or 48 hr) of incubation, the whole cells (Pooled, free and adherent cells) were collected, fixed and permeabilized with cold 70% ethanol. The fixed cells were washed with PBS and resuspended in RNase A (180 μg/mL) and incubated at room temperature for 30 min.
The cells were then washed with PBS (pH=7.4, Sigma-Aldrich, Inc) and the medium was changed to NDM containing different concentrations (0, 6.25, 12.5, or 25 μM) of Akt inhibitor III molecule (Calbiochem, CA, USA). After the specified time of incubation, the cells were washed again with PBS, then 100 μL of DMEM medium with 10% WST-8 solution was added to the wells, and the plate was incubated for a further 2 hours. Then, the absorbance of the wells at 450 nm was measured using HTS Multi-Mode Microplate Reader (BioTek Instruments). The absorbance is proportional to the number of viable cells in the medium.

Cell viability was expressed as percentage relative to cells treated with 0 μM of Akt inhibitor III molecule.

### Statistical analysis

All results were obtained from at least three independent experiments and were expressed as mean ± standard deviation. Statistical comparison was conducted using Student’s t-test after one-way analysis of variance (ANOVA) using GraphPad Prism 5 statistical software (GraphPad, La Jolla, CA) and Excel software (Microsoft, Redwood, WA). The results were considered to be significant when the probability values (P) were less than 0.001.

## Results

### Survival of HeLa cells under nutrient-deprived conditions

To examine the tolerance for nutrient deprivation, cell survival under extreme nutrient starvation was examined by using medium containing only vitamins and electrolytes for culturing. After 24 hr of starvation more than 84% of the cells could survive under these extreme conditions, as shown in Figure 1. More interestingly, more than 12% of the cells tolerated the starvation for 48 hr.

### Effect of starvation on cell cycle and apoptosis of HeLa cells

The effect of starvation on cell cycle distribution and the quantitative analysis of apoptotic cells were investigated using propidium iodide staining to observe DNA content in the cells, as shown in Figure 2. The

---

**Figure 1. Survival of HeLa Cells under Nutrient-Deprived Conditions.** Survival of cells after different time points of culturing the cells in fresh DMEM or NDM was expressed as percentage relative to that at 0 hr which is considered as 100%. Data represent mean ± SD. DMEM, Dulbecco’s Modified Eagle’s Medium; NDM, nutrient-deprived medium.
results showed that starvation, when compared to cells cultured in DMEM, significantly increased (P < 0.001) the percentage of apoptotic HeLa cells (sub-G1 phase) to 20 ± 0.77% and 67.3 ± 4.29% after 24 hr and 48 hr of starvation, respectively, indicating apoptosis in a time-dependent manner.

Effect of starvation on Akt protein expression

To check the relationship between adaptation of cancer cells to starvation and the level of Akt activation, Akt activation was examined, by immunoblotting with Ser473-p-Akt antibody, in HeLa cells after nutrient deprivation. As shown in Figure 3, there is a significant increase (P < 0.001) in the expression of Ser473-p-Akt protein after starvation in a time-dependent manner when compared to that of cells cultured in normal medium (DMEM). This effect of starvation on Ser473 phospho-Akt protein expression in HeLa cells might explain the high percentage of cell survival.

Effect of Akt inhibitor III molecule on survival of HeLa cells under nutrient-deprived conditions

To clarify the involvement of Akt activation in tolerance, HeLa cells were treated with different concentrations of Akt inhibitor III in NDM for 24 hr and the percentage of viable cells compared to cells cultured in NDM only (untreated cells) was determined by cell counting kit-8 assay. It was found that Akt inhibitor III,
in a concentration-dependent manner, inhibited the cells proliferation, as shown in Figure 4A. The number of viable cells was decreased to 90 ± 4%, 30.3 ± 2.5%, and 0.4 ± 0.05% when treated with 6.25, 12.5, and 25 µM of Akt inhibitor III molecule, respectively, for 24 hr.

For more clarification of the involvement of Akt activation in tolerance, the cells were treated with 0 and 12.5 µM of Akt inhibitor III in NDM and the percentage of viable cells compared to cells treated with 0 µM of Akt inhibitor III was determined at different time intervals, Figure 4B. The number of viable cells was decreased in a time-dependent manner. These results suggest that the decay of viable cells number and the increase of the percentage of apoptotic cells following starvation might be dependent on Akt activation status.

**Discussion**

Because of their intrinsic unregulated growth program due to genetic alterations, tumors continuously grow. In general, tumors are always exposed to poor nutrition because of insufficient vascularization (Helmlinger et al., 1997; Dang and Semenza, 1999). Generally without neovascularization or angiogenesis, tumor size is limited (Helmlinger et al., 1997). Metabolic stress triggers gene expression and signal transduction, causing the synthesis of vascular endothelial growth factors and angiogenic factors, resulting in greater metastatic potential, neovascularization, invasion and tumor growth (Holash et al., 1999; Rofstad and Danielsen, 1999; Shaheen et al., 1999). This is the reason why angiogenesis is considered one of the indicators for tumor progression. There are two ways of adaptation to nutrient insufficiency that could be interlinked but distinct from each other. The first way, widely accepted, is by increasing the supply. The second way is austerity, tolerating insufficiency. By angiogenesis, tumors grow beyond their ability to improve nutrient supplies. That is why necrotic foci are often associated with tumors. The tumor cells that have the ability to survive unfavorable conditions might be malignant.

Although neovascularization is important for tumor progression as suggested by most studies, less attention has been directed to the tolerance for poor nutritional conditions. It was observed that short periods of glucose and glutamine starvation for breast cancer cells made the cells rounded and induced apoptosis by mitochondrial dysfunction and generation of reactive oxygen species (Visagie et al., 2015). Also, it was found that Warburg effect was increased in cancer cells, cultured under low nutrient conditions, through activation of pyruvate dehydrogenase kinase (Wu et al., 2013). Our results showed that HeLa cells had acquired tolerance for nutrient deprivation and could survive for long periods, more than 48 hours, even under extremely nutrient-starved conditions.

In the present work, tolerance was closely associated with the expression of high levels of Ser\(^{473}\)p-Akt protein. Recent investigations suggested that Akt is highly expressed in pancreatic and ovarian cancers, and the high level of expression was associated with increased tumorigenicity, poor prognosis and tolerance to nutrient-deprived conditions (Cheng et al., 1996; Miwa et al., 1996; Moore et al., 1998; Ruggeri et al., 1998; Shayesteh et al., 1999; Izuishi et al., 2000; Awale et al., 2006; Awale et al., 2008; Calastretti et al., 2014; Jones et al., 2014). Moreover, expression of constitutively active forms of Akt could prevent cell death upon growth factors removal (Song et al., 2005). Furthermore, it was reported that a site-specific phosphorylation of Akt, Ser\(^{473}\)p-Akt and Thr\(^{308}\)p-Akt, was observed in ovarian, breast, lung, colon, and kidney cancer cell lines subjected to transient and prolonged glucose deprivation, respectively (Gao et al., 2014). These observations lead us to hypothesize that HeLa cells sensitivity to starvation is, in part, dependent on Akt activation status as tolerance for nutrient starvation was found to be associated with high levels of p-Akt.

In addition, the tolerance to nutrient starvation, as shown in the present study, can remarkably be inhibited by Akt inhibitor III in a concentration-dependent as well as time-dependent manner. These results are consistent with others who used MK-2206, an AKT inhibitor, to inhibit the tolerance and decrease the survival of cancer cells subjected to glucose deprivation (Gao et al., 2014). In conclusion, the modulation of Akt activity was found to affect the ability of HeLa cells to tolerate nutrient starvation. Our present findings might be able to provide a possible understanding and may help to suggest new approaches designed to prevent cancer cells' metabolic adaptation. We believe that our results have important implications for new cancer therapies and open a new area of research on the biological nature of cervical cancer. Further understanding of these stress pathways and their regulation is necessary to provide new therapeutic strategies preventing austerity.
