Diffusive relaxation to equilibria for an extended reaction–diffusion system on the real line

THIERRY GALLAY and SINIŠA SLIJEPČEVIĆ

Abstract. We study the longtime behavior of the solutions of a two-component reaction–diffusion system on the real line, which describes the basic chemical reaction $A \rightleftharpoons 2B$. Assuming that the initial densities of the species $A$, $B$ are bounded and nonnegative, we prove that the solution converges uniformly on compact sets to the manifold $E$ of all spatially homogeneous chemical equilibria. The result holds even if the species diffuse at very different rates, but the proof is substantially simpler for equal diffusivities. In the spirit of our previous work on extended dissipative systems (Gallay and Slijepčević, J Dyn Differ Equ 27:653–682, 2015), our approach relies on localized energy estimates, and provides an explicit bound for the time needed to reach a neighborhood of the manifold $E$ starting from arbitrary initial data. The solutions we consider typically do not converge to a single equilibrium as $t \to +\infty$, but they are always quasiconvergent in the sense that their $\omega$-limit sets consist of chemical equilibria.

1. Introduction

Reaction–diffusion systems satisfying a detailed or complex balance condition provide interesting examples of evolution equations where the qualitative behavior of the solutions can be studied using entropy methods. Such systems typically describe reversible chemical reactions of the form

$$
\alpha_1 A_1 + \cdots + \alpha_n A_n \rightleftharpoons \frac{k}{k'} \beta_1 A_1 + \cdots + \beta_n A_n ,
$$

where $A_1, \ldots, A_n$ denote the reactant and product species, $k, k' > 0$ are the reaction rates, and the nonnegative integers $\alpha_i, \beta_i (i = 1, \ldots, n)$ are the stoichiometric coefficients. According to the law of mass action, the concentration $c_i(x, t)$ of the species $A_i$ satisfies the reaction–diffusion equation

$$
\partial_t c_i = d_i \Delta c_i + (\beta_i - \alpha_i) \left( k \prod_{j=1}^{n} c_j^{\alpha_j} - k' \prod_{j=1}^{n} c_j^{\beta_j} \right), \quad i = 1, \ldots, n ,
$$

where $\Delta$ is the Laplace operator acting on the space variable $x$, and $d_i > 0$ denotes the diffusion coefficient of species $A_i$. We refer the reader to Horn and Jackson [27], van der Schaft et al. [43], Desvillettes et al. [9] and Mielke [31] for a more detailed mathematical modeling of chemical reactions, including the realistic situation where
several reactions occur at the same time. For general kinetic systems, there is a notion of detailed balance, which asserts that all reactions are reversible and individually in balance at each equilibrium state, and a weaker notion of complex balance, which only requires that each reactant or product complex is globally at equilibrium if all reactions are taken into account. In the present paper, we focus on a particular example of the single-reaction system (1.2), for which the detailed balance condition is automatically satisfied.

In recent years, many authors investigated the longtime behavior of solutions to reaction–diffusion systems with complex or detailed balance, assuming that the reaction takes place in a bounded domain $\Omega \subset \mathbb{R}^N$ and using an entropy method that we briefly explain in the case of system (1.2) with $k = k'$. If $c(t) = (c_1(t), \ldots, c_n(t))$ is a solution of (1.2) in $\Omega$ satisfying no-flux boundary conditions on $\partial \Omega$, we have the entropy dissipation law $\frac{d}{dt} \Phi(c(t)) = -D(c(t))$, where $\Phi$ is the entropy function defined by

$$
\Phi(c) = \sum_{i=1}^{n} \int_{\Omega} \phi(c_i(x)) \, dx, \quad \phi(z) = z \log(z) - z + 1,
$$

and $D$ is the entropy dissipation

$$
D(c) = \sum_{i=1}^{n} d_i \int_{\Omega} \frac{\left| \nabla c_i(x) \right|^2}{c_i(x)} \, dx + k \int_{\Omega} \log\left( \frac{B(x)}{A(x)} \right) \left( B(x) - A(x) \right) \, dx,
$$

where $A(x) = \prod c_j(x)^{\alpha_j}, B(x) = \prod c_j(x)^{\beta_j}$. It is clear from (1.4) that the entropy dissipation $D(c)$ is nonnegative and vanishes if and only if the concentrations $c_i$ are spatially homogeneous ($\nabla c_i = 0$) and the system is at chemical equilibrium ($A = B$). The entropy is therefore a Lyapunov function for (1.2), and using LaSalle’s invariance principle one deduces that all bounded solutions converge to homogeneous chemical equilibria as $t \to +\infty$ [23,42]. In addition, under appropriate assumptions, the entropy dissipation $D(c)$ can be bounded from below by a multiple of the entropy $\Phi(c)$, or more precisely of the relative entropy $\Phi(c \mid c^*)$ with respect to some equilibrium $c^*$. Such lower bound can be established using a compactness argument [22,24], or invoking functional inequalities such as the logarithmic Sobolev inequality [7–9,15,16,31,37]. This leads to a first-order differential inequality for the relative entropy, which implies exponential convergence in time to equilibria. In its constructive form, this entropy dissipation approach even provides explicit estimates of the convergence rate and of the time needed to reach a neighborhood of the final equilibrium [7,8]. It is also worth mentioning that the reaction–diffusion system (1.2) is actually the gradient flow of the entropy function (1.3) with respect to an appropriate metric based on the Wasserstein distance for the diffusion part of the system [28,30,32]. Finally, we observe that Lyapunov functions such as the entropy (1.3) were also useful to prove global existence of solutions to reaction–diffusion systems; see [4,5,13,14,17,25,35,36,44].

Much less is known about the dynamics of the reaction–diffusion system (1.2) in an unbounded domain such as $\Omega = \mathbb{R}^N$. For bounded solutions, the entropy (1.3) is
typically infinite, and it is known that (1.2) is no longer a gradient system. Solutions such as traveling waves, which exist in many examples, do not converge to equilibria as $t \to +\infty$, at least not in the topology of uniform convergence on $\Omega$. In fact, the best we can hope for in general is quasiconvergence, namely uniform convergence on compact subsets of $\Omega$ to the family of spatially homogeneous equilibria. That property is not automatic at all, and has been established so far only for relatively simple scalar equations where the maximum principle is applicable [11,29,33,34,38–40]. On the other hand, it is important to mention that entropy is still locally dissipated under the evolution defined by (1.2), in the sense that the entropy density $e(x,t)$, the entropy flux $f(x,t)$ and the entropy dissipation $d(x,t)$ satisfy the local entropy balance equation $\partial_t e = \text{div} f - d$. We have the explicit expressions

$$e(x,t) = \sum_{i=1}^{n} \phi(c_i(x,t)),$$

$$f(x,t) = \sum_{i=1}^{n} d_i \log(c_i(x,t))(\nabla c_i(x,t)),$$

$$d(x,t) = \sum_{i=1}^{n} d_i \left| \frac{\nabla c_i(x,t)}{c_i(x,t)} \right|^2 + k \log\left( \frac{B(x,t)}{A(x,t)} \right) \left( B(x,t) - A(x,t) \right),$$

from which we deduce the pointwise estimate $|f|^2 \leq C e \log(2+e)$ for some constant $C > 0$; see Appendix A. This precisely means that the reaction–diffusion system (1.2) is an extended dissipative system in the sense of our previous work [20]. If $N \leq 2$, the results of Gallay and Slijepčević [20] show that all bounded solutions of (1.2) in $\mathbb{R}^N$ converge uniformly on compact subsets to the family of spatially homogeneous equilibria for “almost all” times, i.e., for all times outside a subset of $\mathbb{R}_+$ of zero density in the limit where $t \to +\infty$. In particular, the $\omega$-limit set of any bounded solution, with respect to the topology of uniform convergence on compact sets, always contains an equilibrium. It should be mentioned, however, that extended dissipative systems in the sense of our previous work [20] may have non-quasiconvergent solutions, even in one space dimension. A typical phenomenon that prevents quasiconvergence is the coarsening dynamics that is observed, for instance, in the one-dimensional Allen–Cahn equation [12,38].

In the present paper, we consider a very simple particular case of the reaction–diffusion system (1.2), for which we can prove that all positive solutions converge uniformly on compact sets to the family of spatially homogeneous equilibria. In that example, we only have two species $A, B$ which participate to the simplistic reaction

$$A \xrightleftharpoons[k]{k} 2B. \quad (1.6)$$

Denoting by $u, v$ the concentrations of $A, B$, respectively, we obtain the system

$$u_t(x,t) = au_{xx}(x,t) + k(v(x,t)^2 - u(x,t)),$$

$$v_t(x,t) = bv_{xx}(x,t) + 2k(u(x,t) - v(x,t)^2), \quad (1.7)$$
which is considered on the whole real line $\Omega = \mathbb{R}$. The parameters are the diffusion coefficients $a, b > 0$ and the reaction rate $k > 0$, but scaling arguments reveal that the ratio $a/b$ is the only relevant quantity. It is not difficult to verify that, given bounded and nonnegative initial data $u_0, v_0$, the system (1.7) has a unique global solution that remains bounded and nonnegative for all positive times; see Proposition 2.1 for a precise statement. Our goal is to investigate the longtime behavior of those solutions, using the local form of the entropy dissipation and some additional properties of the system.

As a warm-up, we consider the case of equal diffusivities $a = b$, which is considerably simpler because the function $w = 2u + v$ then satisfies the one-dimensional heat equation $w_t = aw_{xx}$. Using that observation, it is easy to prove the following result:

**Proposition 1.1.** Assume that $a = b$. For any nonnegative initial data $u_0, v_0 \in L^\infty(\mathbb{R})$, the solution of (1.7) satisfies, for all $t > 0$,

$$t \|u_x(t)\|_{L^\infty}^2 + t \|v_x(t)\|_{L^\infty}^2 + (1 + t) \|u(t) - v(t)\|_{L^\infty}^2 \leq C,$$

(1.8)

where the constant only depends on the parameters $a, k$ and on $\|u_0\|_{L^\infty}, \|v_0\|_{L^\infty}$.

Proposition 1.1 implies that all nonnegative solutions converge, uniformly on compact intervals $I \subset \mathbb{R}$, to the manifold of spatially homogeneous equilibria defined by

$$E = \{(\bar{u}, \bar{v}) \in \mathbb{R}^2_+ ; \bar{u} = \bar{v}^2\};$$

(1.9)

see Corollary 1.3 for a precise statement. In other words, the $\omega$-limit set of any solution, with respect to the topology of uniform convergence on compact sets, is entirely contained in $E$. The proof shows that the decay rates given by (1.8) cannot be improved in general. Moreover, it is clear that the $\omega$-limit set is not always reduced to a single equilibrium, because examples of nonconvergent solutions can be constructed even for the linear heat equation on $\mathbb{R}$; see [6].

The proof Proposition 1.1 heavily relies on the simple evolution equation satisfied by the auxiliary function $w = 2u + v$, which is specific to the case of equal diffusivities. The analysis becomes much more challenging when $a \neq b$, because system (1.7) does not reduce to a scalar equation. Our result in the general case is slightly weaker and can be stated as follows:

**Proposition 1.2.** For any nonnegative initial data $u_0, v_0 \in L^\infty(\mathbb{R})$, the solution of (1.7) satisfies, for all $t > 0$,

$$\|u_x(t)\|_{L^\infty} + \|v_x(t)\|_{L^\infty} \leq \frac{C}{t^{1/2}} \log(2 + t), \quad \|u(t) - v(t)\|_{L^\infty} \leq \frac{C}{(1 + t)^{1/2}},$$

(1.10)

where the constant only depends on the parameters $a, b, k$ and on $\|u_0\|_{L^\infty}, \|v_0\|_{L^\infty}$.  

The decay rates of the derivatives \( u_x, v_x \) in (1.10) agree with (1.8) up to a logarithmic correction, but the estimate of the difference \( u - v^2 \), which measures the distance to the local chemical equilibrium, is substantially weaker in the general case. We conjecture that the discrepancy between the conclusions of Propositions 1.1 and 1.2 is of technical nature and that the optimal estimates (1.8) remain valid when \( a \neq b \). At this point, it is worth mentioning that the bounds (1.10) are actually derived from a uniformly local estimate which fully agrees with the decay rates given in (1.8). Indeed, we shall prove in Sect. 4 that any bounded nonnegative solution to (1.7) satisfies, for any \( t > 0 \),

\[
\sup_{x_0 \in \mathbb{R}} \int_{x_0 - \sqrt{t}}^{x_0 + \sqrt{t}} \left( |u_x(x, t)|^2 + |v_x(x, t)|^2 + |u(x, t) - v(x, t)|^2 \right) \, dx \leq Ct^{-1/2},
\]

(1.11)

where the constant depends only on the parameters \( a, b, k \) and on the initial data. It is obvious that (1.8) implies (1.11), but the converse is not quite true and the best we could obtain so far is the weaker estimate (1.10).

As before, we can conclude that all solutions converge uniformly on compact sets to the manifold \( \mathcal{E} \) as \( t \to +\infty \).

**Corollary 1.3.** Under the assumptions of Proposition 1.2, the solution of (1.7) satisfies, for any time \( t > 0 \) and any bounded interval \( I \subset \mathbb{R} \) of length \( |I| \geq 1 \),

\[
\inf \left\{ \|u(t) - \bar{u}\|_{L^\infty(I)} + \|v(t) - \bar{v}\|_{L^\infty(I)} : (\bar{u}, \bar{v}) \in \mathcal{E} \right\} \leq \frac{C|I|}{|I| + t^{1/2}} \log(2 + t),
\]

(1.12)

where the constant only depends on the parameters \( a, b, k \) and on \( \|u_0\|_{L^\infty}, \|v_0\|_{L^\infty} \).

**Remark 1.4.** It is important to keep in mind that the conclusions of Propositions 1.1 and 1.2 are restricted to nonnegative solutions. As a matter of fact, the dynamics of system (1.7) is completely different if we consider solutions for which the second component \( v \) may take negative values. For instance, if \( a = b = k = 1 \), we can look for solutions of the particular form

\[
\begin{align*}
u(x, t) &= 1 - \frac{3z(x, t)}{4}, \quad v(x, t) = -1 + \frac{3z(x, t)}{2},
\end{align*}
\]

in which case (1.7) reduces to the Fisher-KPP equation \( z_t = z_{xx} + 3z(1 - z) \). That equation has a pulse-like stationary solution given by the explicit formula

\[
\tilde{z}(x) = 1 - \frac{3}{2} \frac{1}{\cosh^2(\sqrt{3}x/2)}, \quad x \in \mathbb{R},
\]

which provides an example of a steady state \((\bar{u}, \bar{v})\) for (1.7) that is not spatially homogeneous nor at chemical equilibrium, in the sense that \( \bar{u} \neq \bar{v}^2 \). Moreover, for any speed \( c > 0 \), the Fisher-KPP equation has traveling wave solutions of the form \( z(x, t) = \varphi(x - ct) \) where the wave profile \( \varphi \) satisfies \( \varphi(-\infty) = 1 \) and \( \varphi(+\infty) = 0 \).
For the corresponding solutions of (1.7), the quantities $\|u_x(t)\|_{L^\infty}$, $\|v_x(t)\|_{L^\infty}$, and $\|u(x) - v(t)^2\|_{L^\infty}$ are bounded away from zero for all times, in sharp contrast with (1.8).

**Remark 1.5.** Our results also apply to the situation where system (1.7) is considered on a bounded interval $I = [0, L]$, with homogeneous Neumann boundary conditions, because the solutions $u, v$ can then be extended to even and $2L$-periodic functions on the whole real line. In that case, the total mass $M = \int_0^L (2u(x,t) + v(x,t)) \, dx$ is a conserved quantity, and the solution necessarily converges to the unique equilibrium $(u_\infty, v_\infty) \in \mathcal{E}$ satisfying $2u_\infty + v_\infty = M/L$. As in (1.12), we have the bound

$$\|u(t) - u_\infty\|_{L^\infty(I)} + \|v(t) - v_\infty\|_{L^\infty(I)} \leq \frac{CL}{L + t^{1/2}} \log(2 + t), \quad t \geq 0,$$

which is far from optimal because, in that particular case, it is known that convergence occurs at exponential rate; see [7] for accurate estimates with explicitly computable constants. However, the conclusion of Proposition 1.2 remains interesting in that situation. In particular, the second estimate in (1.10) shows that the time needed for a solution to enter a neighborhood of the manifold $\mathcal{E}$ depends on the $L^\infty$ norm of the initial data, but *not* on the length $L$ of the interval. In contrast, all estimates obtained in [7] and related works necessarily involve the size of the spatial domain, because they use as a Lyapunov function the total entropy which is an extensive quantity in the thermodynamical sense.

The proof of our main result, Proposition 1.2, is based on localized energy (or entropy) estimates in the spirit of our previous works [19–21]. It turns out that the Boltzmann-type entropy density introduced in (1.5) is not the only possibility. Quite on the contrary, there exist a large family of nonnegative quantities that are locally dissipated under the evolution defined by the two-component system (1.7); see Sect. 3 for a more precise discussion. For simplicity, we chose to use the energy density $e(x,t)$, the energy flux $f(x,t)$, and the energy dissipation $d(x,t)$ given by the following expressions:

$$e = \frac{1}{2} u^2 + \frac{1}{6} v^3, \quad f = a u u_x + \frac{b}{2} v^2 v_x, \quad d = au_x^2 + b u v_x^2 + k(u - v^2)^2.$$  

(1.13)

If $(u, v)$ is any nonnegative solution of (1.7), one readily verifies that the local energy balance $\partial_t e = \partial_x f - d$ is satisfied, as well as the estimate $f^2 \leq Cer$ where $C = \max(2a, 3b/2)$. Altogether, this means that (1.7) is an “extended dissipative system” in the sense of Gallay and Slijepčević [20]. As was already mentioned, our results in [20] provide useful information on the gradient-like dynamics of (1.7), but this is far from sufficient to prove Proposition 1.2. For instance, extended dissipative systems may have traveling wave solutions which, obviously, do not satisfy uniform decay estimates of the form (1.10).
To go beyond the general results established in [20], we follow the same approach as in our previous work [21], where energy methods were developed to study the longtime behavior of solutions for the Navier–Stokes equations in the infinite cylinder \( \mathbb{R} \times \mathbb{T} \). The main idea is to show that the energy dissipation in (1.13) is itself locally dissipated under the evolution defined by (1.7). More precisely, we look for another triple \((\tilde{e}, \tilde{f}, \tilde{d})\) satisfying the local balance \(\partial_t \tilde{e} = \partial_x \tilde{f} - \tilde{d}\), and such that the flux \(|\tilde{f}|\) can be controlled in terms of \(\tilde{e}, \tilde{d}\). We also require that \(\tilde{d} \geq 0\) and that \(\tilde{e} \approx d\), where \(d\) is as in (1.13). We can then use localized energy estimates as in [20,21] to prove that, on any compact interval \([x_0, x_0 + L] \subset \mathbb{R}\), the dissipation \(d(x, t)\) becomes uniformly small for all times \(t \gg L^2\). We even get an explicit upper bound depending only on \(L\) and on the initial data, so that taking the supremum over \(x_0 \in \mathbb{R}\) we arrive at estimate (1.11), which is the crucial step in the proof of Proposition 1.2. In contrast, we emphasize that the bounds one can obtain using the dissipative structure (1.13) alone only show that the supremum of \(d(x, t)\) over \([x_0, x_0 + L]\) becomes small for “almost all” (sufficiently large) times, thus leaving space for non-gradient transient behaviors such as traveling wave propagation or coarsening dynamics.

The existence of a second dissipative structure on top of (1.13) is obviously an important property of system (1.7), which is related to the convexity of the energy density with respect to the metric that turns (1.7) into a gradient system; see [28, 31] for a more detailed discussion of gradient structures and convexity properties of reaction–diffusion systems. This geometric characterization is in turn connected to the Bakry–Émery condition for linear diffusions; see [3,28]. As investigated in [31,32], the convexity methods seem to apply to reaction–diffusion systems of the form (1.2) only under some restrictions on the parameters, and furthermore they do not extend in a straightforward way to unbounded domains. It would be interesting to determine if the existence of the second dissipative structure still holds for other systems of the form (1.2), such as those considered in Sect. 6, and to establish a more explicit connection with the convexity of the gradient structure in bounded domains, but so far we have no general result in that direction. We mention that the idea of studying the variation of the entropy dissipation, or equivalently the second variation of the entropy, is quite common in kinetic theory, see [10], as well as in fluid mechanics, see [1] for a recent review on the subject.

The rest of this paper is organized as follows. In Sect. 2, we study the Cauchy problem for the reaction–diffusion system (1.7), and we prove Proposition 1.1 and Corollary 1.3. After these preliminaries, we investigate in Sect. 3 various dissipative structures of the form (1.13), which play a key role in our analysis. The proof of Proposition 1.2 is completed in Sect. 4, where we use localized energy estimates inspired from our previous works [20,21]. Section 5 is devoted to the stability analysis of spatially homogeneous equilibria \((\bar{u}, \bar{v}) \in \mathcal{E}\), which provides useful insight on the decay rates of the solutions. In Sect. 6, we briefly discuss the potential applicability of our method to more general reaction–diffusion systems of the form (1.2), and we mention some open problems.
2. Preliminary results

We first prove that system (1.7) is globally well posed for all initial data \( u_0, v_0 \) that are bounded and nonnegative. This is a rather classical statement, which can be deduced from more general results on reaction–diffusion systems with quadratic nonlinearities; see, e.g., \([25,35,44]\). For the reader’s convenience, we give here a simple and self-contained proof.

Without loss of generality, we assume henceforth that \( k = 1 \). We denote by \( X = C_{bu}(\mathbb{R}) \) the Banach space of all bounded and uniformly continuous functions \( f : \mathbb{R} \to \mathbb{R} \), equipped with the uniform norm \( \| f \|_{L^\infty} \). Since we are interested in nonnegative solutions of (1.7), we also define the positive cone \( X^+ = \{ f \in X ; \ f(x) \geq 0 \, \forall x \in \mathbb{R} \} \).

**Proposition 2.1.** For all initial data \( (u_0, v_0) \in X^2_+ \), system (1.7) has a unique global (mild) solution \((u, v) \in C^0([0, +\infty), X^2)\) such that \((u(0), v(0)) = (u_0, v_0)\). Moreover \((u(t), v(t)) \in X^2_+ \) for all \( t \geq 0 \), and the following estimates hold:

\[
\max\left(\|u(t)\|_{L^\infty}, \|v(t)\|_{L^2}^2\right) \leq \max(\|u_0\|_{L^\infty}, \|v_0\|_{L^\infty}^2),
\]

\[2\|u(t)\|_{L^\infty} + \|v(t)\|_{L^\infty} \leq 2\|u_0\|_{L^\infty} + \|v_0\|_{L^\infty}.
\]

**Proof.** Local existence of solutions in \( X^2 \) can be established by applying a standard fixed point argument to the integral equation

\[
\begin{pmatrix}
  u(t) \\
  v(t)
\end{pmatrix} = \begin{pmatrix}
  S(at) & 0 \\
  0 & S(bt)
\end{pmatrix}\begin{pmatrix}
  u_0 \\
  v_0
\end{pmatrix} + \int_0^t \begin{pmatrix}
  S(a(t-s)) & 0 \\
  0 & S(b(t-s))
\end{pmatrix}\begin{pmatrix}
  v(s)^2 - u(s) \\
  2(u(s) - v(s))^2
\end{pmatrix} \, ds,
\]

(2.2)

where \( S(t) = \exp(t \partial_x^2) \) is the one-dimensional heat semigroup; see, e.g., \([26, \text{Chapter 3}]\). Since the nonlinearity is a polynomial of degree two, the local existence time \( T > 0 \) given by the fixed point argument is no smaller than \( T_0(1 + \|u_0\|_{L^\infty} + \|v_0\|_{L^\infty})^{-1} \) for some constant \( T_0 > 0 \). This shows that any local solution can be extended to a global one, unless the quantity \( \|u(t)\|_{L^\infty} + \|v(t)\|_{L^\infty} \) blows up in finite time. It remains to show that nonnegative solutions satisfy the estimates (2.1), so that blow-up cannot occur.

Assume that \((u_0, v_0) \in X^2_+ \) and let \((u, v) \in C^0([0, T_\ast), X^2)\) be the maximal solution of (1.7) with initial data \((u_0, v_0)\). This solution is smooth for positive times, and the first component satisfies \( u_t = au_{xx} + v^2 - u \geq au_{xx} - u \) for \( t \in (0, T_\ast) \). Applying the parabolic maximum principle \([41]\), we deduce that \( u(t) \in X^+ \) for all \( t \in (0, T_\ast) \). The second component in turn satisfies \( v_t = bv_{xx} + 2(u - v^2) \geq bv_{xx} - 2v^2 \), and another application of the maximum principle shows that \( v(t) \in X^+ \) too. So the positive cone \( X^2_+ \) is invariant under the evolution defined by (1.7).

Another important observation is that (1.7) is a cooperative reaction–diffusion system in \( X^2_+ \), in the sense that the reaction terms in (1.7) satisfy

\[
\frac{d}{dv}(v^2 - u) = 2v \geq 0, \quad \frac{d}{du} (2(u - v^2)) = 2 \geq 0.
\]
As is well known, such a system obeys a (component-wise) comparison principle \cite{45}. In our case, this means that, if \((u, v)\) and \((\bar{u}, \bar{v})\) are two solutions of (1.7) in \(X^2_+\), and if the initial data satisfy \(u_0 \leq \bar{u}_0\) and \(v_0 \leq \bar{v}_0\), then \(u(t) \leq \bar{u}(t)\) and \(v(t) \leq \bar{v}(t)\) as long as the solutions are defined. We use that principle to compare our nonnegative solution \((u, v)\) to the solution \((\bar{u}, \bar{v})\) of the ODE system

\[
\frac{d}{dt} \bar{u}(t) = \bar{v}(t)^2 - \bar{u}(t), \quad \frac{d}{dt} \bar{v}(t) = 2(\bar{u}(t) - \bar{v}(t)^2),
\]

with initial data \(\bar{u}_0 = \|u_0\|\_\infty, \bar{v}_0 = \|v_0\|\_\infty\). The dynamics of (2.3) in the positive quadrant is very simple: The solution stays on the line \(L_0 = \{ (\bar{u}, \bar{v}) \in \mathbb{R}^2_+ ; 2\bar{u} + \bar{v} = 2\bar{u}_0 + \bar{v}_0 \}\) for all times and converges to the unique equilibrium \((\bar{u}_*, \bar{v}_*) \in L_0 \cap \mathcal{E}\), where \(\mathcal{E}\) is defined in (1.9); see Fig. 1. In particular, we have \(\max(\bar{u}(t), \bar{v}(t)^2) \leq \max(\bar{u}_0, \bar{v}_0^2)\) for all \(t \geq 0\). Applying the comparison principle, we conclude that our solution \((u, v)\) in \(C^0([0, T_*], X^2)\) satisfies estimates (2.1) for all \(t \in [0, T_*]\), which implies that \(T_* = +\infty\). \hfill \(\square\)

Remark 2.2. The equilibrium \((\bar{u}_*, \bar{v}_*)\) which attracts the solution of (2.3) is given by

\[
\bar{u}_* = \bar{v}_*^2, \quad \text{and} \quad \bar{v}_* = \frac{1}{4} \left( -1 + \sqrt{1 + 16\bar{u}_0 + 8\bar{v}_0} \right).
\]

As is clear from Fig. 1, we have the optimal bounds

\[
\min(\bar{u}_0, \bar{u}_*) \leq \bar{u}(t) \leq \max(\bar{u}_0, \bar{u}_*), \quad \min(\bar{v}_0, \bar{v}_*) \leq \bar{v}(t) \leq \max(\bar{v}_0, \bar{v}_*),
\]

which can be used to improve somewhat (2.1).

Remark 2.3. In a similar way, we can use the comparison principle to show that the solution of (1.7) given by Proposition 2.1 satisfies \(u(x, t) \geq \underline{u}(t)\) and \(v(x, t) \geq \underline{v}(t)\), where \((\underline{u}(t), \underline{v}(t))\) is the solution of the ODE system (2.3) with initial data

\[
\underline{u}_0 = \inf_{x \in \mathbb{R}} u_0(x), \quad \underline{v}_0 = \inf_{x \in \mathbb{R}} v_0(x).
\]

Two interesting conclusions can be drawn using such lower bounds. First, if \(\underline{v}_0 \geq \delta > 0\) for some \(\delta > 0\), then \(v(x, t) \geq 2\delta(1 + \sqrt{1 + 8\delta})^{-1}\) for all \(x \in \mathbb{R}\) and all \(t \geq 0\). This observation will be used in the proof of Proposition 1.2. Second, any homogeneous equilibrium \((\bar{u}, \bar{v}) \in \mathcal{E}\) is stable (in the sense of Lyapunov) in the uniform topology: For any \(\epsilon > 0\), there exists \(\delta > 0\) such that, if \(\|u_0 - \bar{u}\|_{L^\infty} + \|v_0 - \bar{v}\|_{L^\infty} \leq \delta\), then \(\|u(t) - \bar{u}\|_{L^\infty} + \|v(t) - \bar{v}\|_{L^\infty} \leq \epsilon\) for all \(t \geq 0\). An explicit expression for \(\delta\) in terms of \(\epsilon\) and \(\bar{u}, \bar{v}\) can be deduced from (2.4), (2.5).

Remark 2.4. In Proposition 2.1, we assume for simplicity that the initial data \(u_0, v_0\) are bounded and uniformly continuous, but system (1.7) remains globally well posed for all nonnegative data \((u_0, v_0) \in L^\infty(\mathbb{R})^2\). The only difference in the proof is that, when \(t \to 0\), the first term in the integral equation (2.2) does not converge to \((u_0, v_0)\) in the uniform norm, but only in the weak-* topology of \(L^\infty(\mathbb{R})\).
Figure 1. A sketch of the dynamics of the ODE system \( \dot{u} = v^2 - u \), \( \dot{v} = 2(u - v^2) \), which represents the kinetic part of (1.7). The solution starting from the initial data \((u_0, v_0)\) stays on the line \( L_0 = \{ (u, v) ; 2u + v = 2u_0 + v_0 \} \) and converges there to the unique equilibrium \((u^*, v^*) \in L_0 \cap \mathcal{E}\).

**Proof of Proposition 1.1.** We assume here without loss of generality that \( a = b = k = 1 \). Given \((u_0, v_0) \in X_+^2 \), let \((u, v) \in C_0^0([0, +\infty), X^2)\) be the unique global solution of (1.7) with initial data \((u_0, v_0)\). As was already mentioned, the quantity \( w = 2u + v \) satisfies the linear heat equation \( w_t = w_{xx} \) on \( \mathbb{R} \). In particular, we have the estimate

\[
\| w_x(t) \| \leq C \frac{\| w_0 \|}{t^{1/2}} \leq CR \frac{1}{t^{1/2}}, \quad t > 0,
\]

where \( R := 1 + \| u_0 \| + \| v_0 \| \). Here and in what follows, we denote \( \| \cdot \| = \| \cdot \|_{L^\infty} \), and the generic constant \( C \) is always independent of the initial data \((u_0, v_0)\).

We first estimate the derivatives \( u_x(t), v_x(t) \) for \( t \leq t_0 \), where \( t_0 := T_0/R \) is the local existence time appearing in the proof of Proposition 2.1. Differentiating the integral equation (2.2) and using the second inequality in (2.1), we easily obtain

\[
\| u_x(t) \| + \| v_x(t) \| \leq CR \frac{1}{t^{1/2}} + \int_0^t \frac{CR^2}{(t-s)^{1/2}} ds \leq CR \frac{1}{t^{1/2}}, \quad 0 < t \leq t_0.
\]

In particular, we have \( \| u_x(t_0) \| + \| v_x(t_0) \| \leq CR^{3/2} \).

We next observe that the quantity \( q = v_x \) satisfies the linear equation \( q_t = q_{xx} - (1 + 4v)q + w_x \). The corresponding integral equation reads

\[
q(t) = \Sigma(t, t_0)q(t_0) + \int_{t_0}^t \Sigma(t, s)w_x(s) ds, \quad t > t_0,
\]

where \( \Sigma(t, s) \) is the two-parameter semigroup associated with the linear nonautonomous equation \( q_t = q_{xx} - (1 + 4v)q \), assuming that \( v(x, t) \) is given. Since \( v \geq 0 \), the maximum principle implies the pointwise estimate \( \Sigma(t, s) \leq e^{-(t-s)} S(t-s) \), where \( S(t) = \exp(t \partial_x^2) \) is the heat kernel. Using (2.6), (2.7), we thus obtain
\[ \|q(t)\| \leq e^{-(t-t_0)}\|q(t_0)\| + \int_{t_0}^{t} e^{-(t-s)}\|w_x(s)\| \, ds \]
\[ \leq CR^{3/2} e^{-(t-t_0)} + CR \int_{t_0}^{t} e^{-(t-s)} \frac{CR}{s^{1/2}} \, ds \leq \frac{CR^{3/2}}{t^{1/2}}, \quad t > t_0. \] (2.8)

Note that (2.7), (2.8) imply that \(\|q(t)\| \leq CR^{3/2} t^{-1/2}\) for all \(t > 0\).

Similarly, the quantity \(p = u_x\) satisfies the equation \(p_t = p_{xx} - p + 2vq\), and we know from (2.1) that \(\|v(t)\| \leq 2R\) for all \(t \geq 0\). It follows that
\[ \|p(t)\| \leq e^{-(t-t_0)}\|p(t_0)\| + 4R \int_{t_0}^{t} e^{-(t-s)}\|q(s)\| \, ds \]
\[ \leq CR^{3/2} e^{-(t-t_0)} + CR \int_{t_0}^{t} e^{-(t-s)} \frac{R^{5/2}}{s^{1/2}} \, ds \leq \frac{CR^{5/2}}{t^{1/2}}, \quad t > t_0. \] (2.9)

Altogether, we deduce from (2.7) to (2.9) that \(t\|u_x(t)\|^2 + t\|v_x(t)\|^2 \leq CR^5\) for all \(t > 0\), which proves the first part of inequality (1.8).

Finally, the quantity \(\rho = u - v^2\) satisfies the equation \(\rho_t = \rho_{xx} - (1 + 4v)\rho + 2q^2\) as well as the a priori estimate \(\|\rho(t)\| \leq R^2\) for all \(t \geq 0\). Proceeding as above and using (2.8), we find
\[
\|\rho(t)\| \leq e^{-(t-t_0)}\|\rho(t_0)\| + 2 \int_{t_0}^{t} e^{-(t-s)}\|q(s)\|^2 \, ds \leq R^2 e^{-(t-t_0)} + CR \int_{t_0}^{t} e^{-(t-s)} \frac{R^3}{s} \, ds \leq \frac{CR^3 t}{\log(1+R)}, \quad t > t_0.
\] (2.10)

Thus, \((1 + t)\|\rho(t)\| \leq CR^3 \log(1 + R)\) for all \(t \geq 0\), which concludes the proof of (1.8).

\[ \square \]

**Remark 2.5.** Similarly, differentiating with respect to \(x\) the evolution equations for the quantities \(q, p, \rho\) and using an induction argument, one can show that the solution of (1.7) with \(a = b\) satisfies, for each integer \(m \in \mathbb{N}\), an estimate of the form
\[ \|\partial_x^m u(t)\|_{L^\infty} + \|\partial_x^m v(t)\|_{L^\infty} \leq \frac{C_m}{t^{m/2}}, \quad \|\partial_x^m \rho(t)\|_{L^\infty} \leq \frac{C_m}{t^{m/2}}(1 + t), \quad \forall t > 0. \] (2.11)

**Proof of Corollary 1.3.** If \(t \geq |I|^2\), we pick \(x_0 \in I\) and define \(\tilde{v} = v(x_0, t), \tilde{u} = \tilde{v}^2\).

Then \((\tilde{u}, \tilde{v}) \in \mathcal{E}\) and using the first inequality in (1.10) we find
\[ \|v(\cdot, t) - \tilde{v}\|_{L^\infty(I)} = \|v(\cdot, t) - v(x_0, t)\|_{L^\infty(I)} \leq |I| \|v_x(\cdot, t)\|_{L^\infty(I)} \leq \frac{C|I|}{t^{1/2}} \log(2+|t|). \]

Similarly, using in addition the second inequality in (1.10) and recalling that \(|I| \geq 1\), we obtain
\[ \|u(\cdot, t) - \tilde{u}\|_{L^\infty(I)} \leq \|u(\cdot, t) - u(x_0, t)\|_{L^\infty(I)} + |u(x_0, t) - v(x_0, t)^2| \]
Combining these bounds and recalling that \( t \geq |I|^{2/2} \log(2 + t) \).

3. An ordered pair of dissipative structures

We now relax the assumption that \( a = b \) and return to the general case where \( a, b \) are arbitrary positive constants. Assuming without loss of generality that \( k = 1 \), we write system (1.7) in the equivalent form

\[
\begin{align*}
  u_t &= au_{xx} - \rho, \\
  v_t &= bu_{xx} + 2\rho,
\end{align*}
\]

(3.1)

where the auxiliary quantity \( \rho = u - v^2 \) measures the distance to the chemical equilibrium.

As was already mentioned, the proof of Proposition 1.2 relies on local energy estimates and follows the general approach described in [20]. For the nonnegative solutions of (3.1) given by Proposition 2.1, it is convenient to use the energy density \( e(x, t) \), the energy flux \( f(x, t) \), and the energy dissipation \( d(x, t) \) given by (1.13), namely

\[
\begin{align*}
  e &= \frac{1}{2} u^2 + \frac{1}{6} v^3, \\
  f &= au_x u_t + \frac{b}{2} v^2 v_x, \\
  d &= au_x^2 + bvv_x^2 + \rho^2.
\end{align*}
\]

(3.2)

The local energy balance \( \partial_t e = \partial_x f - d \) is easily verified by a direct calculation. The main properties we shall use are the positivity of the energy \( e \) and the dissipation \( d \), as well as the pointwise estimate \( f^2 \leq C ed \), where \( C > 0 \) depends only on \( a, b \). In [20], an evolution equation equipped with a triple \((e, f, d)\) satisfying the above properties is called an “extended dissipative system.” According to that terminology, we shall refer to the triple (3.2) as an “EDS structure” for system (3.1).

The essential step in the proof of Proposition 1.2 is the construction of a second EDS structure \((\tilde{e}, \tilde{f}, \tilde{d})\) for (3.1), where the new energy density \( \tilde{e} \) is bounded from above by a multiple of the energy dissipation \( d \) in the first EDS structure. It is quite natural to look for \( \tilde{e} \) as a linear combination of the quantities \( u_x^2, vv_x^2 \), and \( \rho^2 \) that appear in the expression of \( d \) in (3.2).

**Lemma 3.1.** For all values of the parameters \( \alpha, \beta > 0 \) the quantities \( \tilde{e}, \tilde{f}, \tilde{d} \) defined by

\[
\begin{align*}
  \tilde{e} &= \frac{\alpha}{2} u_x^2 + \frac{\beta}{2} vv_x^2 + \frac{1}{2} \rho^2, \\
  \tilde{f} &= au_x u_t + \beta vv_x v_t - \frac{\beta b}{6} v_x^3 + \frac{\beta}{2} \rho \rho_x, \\
  \tilde{d} &= aau_{xx}^2 + bvv_{xx}^2 + (1 + 4v)\rho^2 \\
  &+ \frac{\beta}{2} \rho_x^2 - (a + \alpha - \beta/2) \rho u_{xx} + 2(b + \beta/2) \rho vv_{xx},
\end{align*}
\]

(3.3)

satisfy the local energy balance \( \partial_t \tilde{e} = \partial_x \tilde{f} - \tilde{d} \).
Proof. Differentiating \( \tilde{e} \) with respect to time and using (3.1), we find by a direct calculation

\[
\partial_t \tilde{e} = \alpha u_x u_{xt} + \beta v v_x v_{xt} + \frac{\beta}{2} v_x^2 v_t + \rho \rho_t
\]

\[
= \left( \alpha u_x u_t + \beta v v_x v_t \right)_x - \alpha u_{xx} u_t - \beta v v_{xx} v_t - \frac{\beta}{2} v_x^2 v_t + \rho \rho_t
\]

\[
= \left( \alpha u_x u_t + \beta v v_x v_t - \frac{\beta b}{6} v_x^3 \right)_x - \alpha a u_{xx}^2 - \beta b v v_{xx}^2 - (1 + 4v) \rho^2
\]

\[
- \beta v_x^2 + (a + \alpha) \rho u_{xx} - 2(b + \beta) \rho v v_{xx} .
\]

(3.4)

The last line collects the terms which have no definite sign and cannot be incorporated in the flux \( \tilde{f} \). Among them, the terms involving \( \rho_{xx} \) and \( \rho v v_{xx} \) can be controlled by the negative terms in the previous line. This is not the case, however, of the term \(-\beta v_x^2\), which is potentially problematic. The trick here is to use the identity

\[
\rho v_x^2 = \frac{\rho}{2} \left( u_{xx} - 2 v v_{xx} - \rho_{xx} \right),
\]

(3.5)

which is easily obtained by differentiating twice the relation \( \rho = u - v^2 \) with respect to \( x \). If we replace (3.5) into (3.4) and if we observe in addition that \( \rho \rho_{xx} = (\rho \rho_x)_x - \rho_x^2 \), we conclude that \( \partial_t \tilde{e} = \partial_x \tilde{f} - \tilde{d} \), where \( \tilde{e} , \tilde{f} , \tilde{d} \) are defined in (3.3).

It remains to choose the free parameters \( \alpha, \beta \) so that the dissipation \( \tilde{d} \) is positive. In the third line of (3.3), the last two terms involving \( \rho_{xx} \) and \( \rho v v_{xx} \) have no definite sign, but (as already mentioned) we can use Young’s inequality to control them in terms of the positive quantities \( u_{xx}^2, v v_{xx}^2, \) and \( (1 + 4v) \rho^2 \). This procedure works if and only if

\[
(a + \alpha - \beta/2)^2 < 4a \alpha , \quad (b + \beta/2)^2 < 4b \beta .
\]

(3.6)

It is always possible to chose \( \alpha, \beta > 0 \) so that both inequalities in (3.6) are satisfied. A particularly simple solution is \( \alpha = a + b, \beta = 2b \), which we assume henceforth.

We thus find:

**Corollary 3.2.** The quantities \( \tilde{e} , \tilde{f} , \tilde{d} \) defined by

\[
\tilde{e} = \frac{a + b}{2} u_x^2 + b v v_x^2 + \frac{1}{2} \rho^2 ,
\]

\[
\tilde{f} = (a + b) u_x u_t + 2b v v_x v_t - \frac{b^2}{3} v_x^3 + b \rho \rho_x ,
\]

\[
\tilde{d} = a(a + b) u_{xx}^2 + 2b^2 v v_{xx}^2 + (1 + 4v) \rho^2 + b \rho_x^2 - 2a \rho u_{xx} + 4b \rho v v_{xx} ,
\]

(3.7)

satisfy the local energy balance \( \partial_t \tilde{e} = \partial_x \tilde{f} - \tilde{d} \), and there exists a constant \( \gamma > 0 \) depending only on \( a, b \) such that

\[
\tilde{d} \geq \tilde{d}_0 := \gamma \left( u_{xx}^2 + v v_{xx}^2 + (1 + 4v) \rho^2 \right) + b \rho_x^2 .
\]

(3.8)
Remark 3.3. Strictly speaking, the triple \( (\tilde{e}, \tilde{f}, \tilde{d}) \) is not an EDS structure in the sense of [20], because the flux bound \( \tilde{f}^2 \leq C\tilde{e}\tilde{d} \) does not hold. The problem comes from the term involving \( v_x^3 \) in \( \tilde{f} \): It is clearly not possible to bound \( v_x^6 \) pointwise in terms of \( vv_x^2 \) and \( vv_x^2_{xx} \). Nevertheless, we shall see in Sect. 4 that the contribution of that term to the localized energy estimates can be estimated as if the pointwise bound was valid. This suggests that our definition of “extended dissipative system” given in [20] may be too restrictive, and should perhaps be generalized so as to include more general flux terms as in the present example.

The EDS structures (3.2), (3.7) provide a good control on the quantities \( v^2 \), \( v_x^2 \), and \( v_{xx}^2 \) only if the function \( v(x, t) \) is bounded away from zero. As was observed in Remark 2.3, this is the case in particular if \( v_0(x) \geq \delta > 0 \) for some \( \delta > 0 \). However, we are also interested in initial data which do not have that property. In particular we may want to consider the situation where \( (u_0, v_0) = (1, 0) \) when \( x < 0 \) and \( (u_0, v_0) = (0, 1) \) when \( x > 0 \). In that case, the evolution describes the diffusive mixing of the initially separated species \( A, B \).

To handle the case where the second component \( v(x, t) \) is not bounded away from zero, a possibility is to add to the energy density \( e(x, t) \) a small multiple of \( w^2 \), where \( w = 2u + v \).

Lemma 3.4. If \( \theta > 0 \) is sufficiently small, the quantities \( e_1(x, t) \), \( f_1(x, t) \), \( d_1(x, t) \) defined by

\[
\begin{align*}
e_1 &= e + \theta w^2/2, \\
f_1 &= f + \theta bww_x + 2\theta(a-b)wu_x, \\
d_1 &= d + \theta bw_x^2 + 2\theta(a-b)w_xu_x,
\end{align*}
\] (3.9)

satisfy the energy balance \( \partial_t e_1 = \partial_x f_1 - d_1 \), and there exists a constant \( c > 0 \) such that

\[
e_1 \geq c(u^2 + (1 + v)v^2), \quad d_1 \geq c(u_x^2 + (1 + v)v_x^2 + \rho^2).
\] (3.10)

Similarly, the quantities \( \tilde{e}_1(x, t) \), \( \tilde{f}_1(x, t) \), \( \tilde{d}_1(x, t) \) defined by

\[
\begin{align*}
\tilde{e}_1 &= \tilde{e} + \theta w_x^2/2, \\
\tilde{f}_1 &= \tilde{f} + \theta w_xw_t, \\
\tilde{d}_1 &= \tilde{d} + \theta bw_{xx}^2 + 2\theta(a-b)w_{xx}u_{xx},
\end{align*}
\] (3.11)

satisfy the energy balance \( \partial_t \tilde{e}_1 = \partial_x \tilde{f}_1 - \tilde{d}_1 \) as well as the lower bounds

\[
\begin{align*}
\tilde{e}_1 &\geq c(u_x^2 + (1 + v)v_x^2 + \rho^2), \\
\tilde{d}_1 &\geq c(u_{xx}^2 + (1 + v)v_{xx}^2 + \rho_x^2 + (1 + v)\rho^2).
\end{align*}
\] (3.12)

Proof. Since \( w_t = 2au_{xx} + bw_{xx} = bw_{xx} + 2(a-b)u_{xx} \), it is straightforward to verify that the additional terms involving the parameter \( \theta \) in (3.9), (3.11) do not destroy the local energy balances. The lower bounds (3.10) are easily obtained, for
sufficiently small \( \theta > 0 \), using the definitions of the quantities \( e_1, d_1 \) and the elementary inequalities
\[
w^2 \geq v^2,
\]
\[
bw_x^2 + 2(a - b)w_xu_x = 4au_x^2 + 2(a + b)u_xv_x + bv_x^2 \geq \frac{b}{2}v_x^2 - \frac{2(a^2 + b^2)}{b}u_x^2.
\]
Estimates (3.12) are obtained similarly, using in addition the lower bound (3.8).  \( \square \)

4. Uniformly local energy estimates

In this section, we complete the proof of our main result, Proposition 1.2, using the dissipative structures introduced in Sect. 3. We fix the parameters \( a, b > 0 \), and we consider a global solution \( (u, v) \in C^0([0, +\infty), X^2) \) of system (3.1) with initial data \( (u_0, v_0) \in X^2_+ \), as given by Proposition 2.1. Following our previous works [20,21], our strategy is to control the behavior of the solution \( (u(t), v(t)) \) for large times using localized energy estimates.

For convenience, we first prove Proposition 1.2 under the additional assumption that the solution of (3.1) satisfies
\[
\inf_{t \geq 0} \inf_{x \in \mathbb{R}} v(x, t) \geq \delta,
\]
for some \( \delta > 0 \). (4.1)

As was observed in Remark 2.3, this is the case if the initial function \( v_0(x) = v(x, 0) \) is bounded away from zero. Assumption 4.1 allows us to use the relatively simple EDS structures (3.2), (3.7) instead of the more complicated ones introduced in Lemma 3.4, and this makes the argument somewhat easier to follow. The proof is, however, completely similar in the general case; see Sect. 4.4.

Given \( \epsilon > 0 \) and \( x_0 \in \mathbb{R} \), we define the localization function
\[
\chi(x) = \chi_{\epsilon, x_0}(x) := \frac{1}{\cosh(\epsilon(x - x_0))}, \quad x \in \mathbb{R}.
\]
This function is smooth and satisfies the bounds
\[
0 < \chi(x) \leq 1, \quad |\chi'(x)| \leq \epsilon \chi(x), \quad |\chi''(x)| \leq \epsilon^2 \chi(x), \quad x \in \mathbb{R}.
\]
Note also that \( \int_{\mathbb{R}} \chi(x) \, dx = \pi/\epsilon \). The translation parameter \( x_0 \) plays no role in the subsequent calculations, but at the end we shall take the supremum over \( x_0 \in \mathbb{R} \) to obtain uniformly local estimates. In contrast, the dilation parameter \( \epsilon > 0 \) is crucial and will be chosen in an appropriate time-dependent way.

4.1. The localized energy and its dissipation

We first exploit the EDS structure (3.2). We fix some observation time \( T > 0 \) and we consider the localized energy
\[
E(t) = \int_{\mathbb{R}} \chi(x) e(x, t) \, dx = \int_{\mathbb{R}} \chi(x) \left( \frac{1}{2}u(x, t)^2 + \frac{1}{6}v(x, t)^3 \right) \, dx, \quad t \in [0, T].
\]
Note that this quantity is well defined thanks to the localization function $\chi$, which is integrable. If $t > 0$, we also introduce the associated energy dissipation

$$D(t) = \int_{\mathbb{R}} \chi(x) \, d(x, t) \, dx = \int_{\mathbb{R}} \chi(x) \left( au_x(x, t)^2 + b v(x, t) v_x(x, t)^2 + \rho(x, t)^2 \right) \, dx.$$ 

Since the solution $(u, v)$ of the parabolic system (3.1) is smooth for $t > 0$, it is straightforward to verify that $E \in C^0([0, T]) \cap C^1((0, T))$ and that

$$E'(t) = \int_{\mathbb{R}} \chi(x) \, \partial_t e(x, t) \, dx = \int_{\mathbb{R}} \chi(x) \left( \partial_x f(x, t) - d(x, t) \right) \, dx$$

$$= -\int_{\mathbb{R}} \chi'(x) f(x, t) \, dx - D(t) . \tag{4.4}$$

To bound the flux term, we use (4.3) and the pointwise estimate $f^2 \leq C_0 \rho$, where $C_0 > 0$ depends on the parameters $a, b$. Applying Young’s inequality, we obtain

$$\left| \int_{\mathbb{R}} \chi(x) f(x, t) \, dx \right| \leq \epsilon \int_{\mathbb{R}} \chi \left( C_0 \rho \right)^{1/2} \, dx \leq \frac{1}{2} D(t) + \frac{C_0 \epsilon^2}{2} E(t) .$$

At this point, we choose the dilation parameter $\epsilon$ so that

$$C_0 \epsilon^2 = \frac{1}{T} . \tag{4.5}$$

We thus obtain the differential inequality $E'(t) \leq -\frac{1}{2} D(t) + \frac{1}{2T} E(t)$, which can be integrated using Grönwall’s lemma to give the useful estimate

$$E(T) + \frac{1}{2} \int_0^T D(t) \, dt \leq \epsilon^{1/2} E(0) , \tag{4.6}$$

where $\epsilon = \exp(1)$. Indeed, defining $\Phi(t) = E(t) + \frac{1}{2} \int_0^t D(s) \, ds$, we have $\Phi(0) = E(0)$ and

$$\Phi'(t) = E'(t) + \frac{1}{2} D(t) \leq \frac{1}{2T} E(t) \leq \frac{1}{2T} \Phi(t) , \quad t \in (0, T) ,$$

so that $\Phi(t) \leq E(0) \exp(t/(2T))$ for $t \in [0, T]$. Setting $t = T$ we arrive at (4.6).

Next, we introduce integrated quantities related to the second EDS structure (3.7). For all $t \in (0, T)$, we define

$$\tilde{E}(t) = \int_{\mathbb{R}} \chi(x) \, \tilde{e}(x, t) \, dx = \int_{\mathbb{R}} \chi(x) \left( \frac{a + b}{2} u_x^2 + b v v_x + \frac{1}{2} \rho^2 \right)(x, t) \, dx ,$$

$$\tilde{D}(t) = \int_{\mathbb{R}} \chi(x) \, \tilde{d}(x, t) \, dx = \int_{\mathbb{R}} \chi(x) \left( \gamma u_{xx} + \gamma v v_{xx} + \gamma (1 + 4v) \rho^2 + b \rho_x^2 \right)(x, t) \, dx ,$$

where $\gamma > 0$ is as in Corollary 3.2. The same calculation as in (4.4) leads to

$$\tilde{E}'(t) = -\int_{\mathbb{R}} \chi'(x) \tilde{f}(x, t) \, dx - \int_{\mathbb{R}} \chi(x) \, \tilde{d}(x, t) \, dx \leq -\int_{\mathbb{R}} \chi'(x) \tilde{f}(x, t) \, dx - \tilde{D}(t) ,$$
where the inequality follows from (3.8). The difficulty here is that the flux term does not satisfy a pointwise estimate of the form $\tilde{f}^2 \leq C \tilde{e} \tilde{d}_0$; see Remark 3.3. However, we can decompose

$$\tilde{f} = \tilde{f}_0 - \frac{b^2}{3} v_x^3,$$

where $\tilde{f}_0 = (a + b)u_x u_t + 2b v v_x v_t + b \rho \rho_x$,

and it is easy to check that $\tilde{f}_0^2 \leq C_1 \tilde{e} \tilde{d}_0$ for some $C_1 > 0$. In particular, we find as before

$$\left| \int_{\mathbb{R}} \chi'(x) \tilde{f}_0(x, t) \, dx \right| \leq \epsilon \int_{\mathbb{R}} \chi \left( C_1 \tilde{e} \tilde{d}_0 \right)^{1/2} \, dx \leq \frac{1}{4} \tilde{D}(t) + C_1 \epsilon^2 \tilde{E}(t). \quad (4.7)$$

As for the term involving $v_x^3$, we integrate by parts to obtain the identity

$$\int_{\mathbb{R}} \chi' v_x^3 \, dx = - \int_{\mathbb{R}} \chi'' v_x^2 \, dx - 2 \int_{\mathbb{R}} \chi' v v_x v_{xx} \, dx.$$

Using (4.3) and Young’s inequality, we deduce

$$\frac{b^2}{3} \left| \int_{\mathbb{R}} \chi'(x) v_x^3(x, t) \, dx \right| \leq \frac{b \epsilon^2}{3} \tilde{E}(t) + \frac{1}{4} \tilde{D}(t) + \frac{4b^3 \epsilon^2}{9y} \tilde{E}(t). \quad (4.8)$$

The combination of (4.7) and (4.8) gives the desired estimate on the flux term:

$$\left| \int_{\mathbb{R}} \chi'(x) \tilde{f}(x, t) \, dx \right| \leq \frac{1}{2} \tilde{D}(t) + C_2 \epsilon^2 \tilde{E}(t), \quad \text{where } C_2 = C_1 + \frac{b}{3} + \frac{4b^3}{9y}.$$

Integrating the differential inequality $\tilde{E}'(t) \leq -\frac{1}{2} \tilde{D}(t) + C_2 \epsilon^2 \tilde{E}(t)$ over the time interval $[t_0, T]$, where $t_0 \in [0, T]$, we arrive at the estimate

$$\tilde{E}(T) + \frac{1}{2} \int_{t_0}^{T} \tilde{D}(t) \, dt \leq C_3 \tilde{E}(t_0), \quad t_0 \in [0, T], \quad (4.9)$$

where $C_3 = \exp(C_2 \epsilon^2 T) = \exp(C_2/C_0)$.

Finally, we use the crucial fact that the EDS structures (3.2), (3.7) are ordered, in the sense that

$$\tilde{e}(x, t) \leq C_4 d(x, t), \quad \text{where } C_4 = \max \left( 1, \frac{a + b}{2a} \right).$$

In particular, the inequality $\tilde{E}(t) \leq C_4 D(t)$ holds for all $t \in (0, T)$. Thus, if we average (4.9) over $t_0 \in [0, T]$ and use (4.6), we obtain

$$\tilde{E}(T) + \frac{1}{2T} \int_{0}^{T} t \tilde{D}(t) \, dt \leq \frac{C_3}{T} \int_{0}^{T} \tilde{E}(t_0) \, dt_0 \leq \frac{C_3 C_4}{T} \int_{0}^{T} D(t) \, dt \leq \frac{C_5}{T} \tilde{E}(0),$$

(4.10)

where the constant $C_5 = 2 \epsilon^{1/2} C_3 C_4$ only depends on the parameters $a, b$ in the system (3.1) and is in particular independent of the observation time $T > 0$ and of the
solution \((u, v)\) under consideration. It is, however, important to keep in mind that
all integrated quantities \(E, \tilde{E}\) and \(D, \tilde{D}\) depend implicitly on \(T\) through the weight
function \((4.2)\) and the choice \((4.5)\) of the parameter \(\epsilon\).

The bound \((4.10)\) summarizes the information we can obtain from the EDS struc-
tures \((3.2), (3.7)\). It serves as a basis for all estimates we shall derive on the solutions
of \((3.1)\) for large times. A typical application of \((4.10)\) is:

**Lemma 4.1.** There exists a constant \(C_6 > 0\) depending only on the parameters
\(a, b\) such that, for any solution \((u, v)\) \(\in C^0([0, +\infty), \mathbb{R}_+^2)\) of \((3.1)\) with initial data
\((u_0, v_0) \in X^1_+\) and any \(T > 0\), the following inequality holds:

\[
\sup_{x_0 \in \mathbb{R}} \int_{I(x_0, T)} \left( u_x^2 + v v_x^2 + \rho^2 \right) dx \leq C_6 R^3 T^{-1/2},
\]

\((4.11)\)

where \(I(x_0, T) = \{ x \in \mathbb{R} ; |x - x_0| \leq (C_0 T)^{1/2} \}\) and \(R = 1 + \| u_0 \|_{L^\infty} + \| v_0 \|_{L^\infty}\).

**Proof.** The initial energy density satisfies \(e(x, 0) \leq 1/2 \| u_0 \|_{L^\infty}^2 + 1/6 \| v_0 \|_{L^\infty}^3 \leq R^3\), so that

\[
E(0) = \int_{\mathbb{R}} \chi(x) e(x, 0) dx \leq R^3 \int_{\mathbb{R}} \chi(x) dx = \frac{\pi R^3}{\epsilon} = \pi R^3 (C_0 T)^{1/2}.
\]

\((4.12)\)

On the other hand, we have the lower bound \(\tilde{e} \geq \gamma_1 (u_x^2 + v v_x^2 + \rho^2)\) for some constant
\(\gamma_1 > 0\), and it follows from \((4.2)\) that \(\chi(x) \geq \epsilon^{-1}\) when \(|x - x_0| \leq \epsilon^{-1} = (C_0 T)^{1/2}\).

We thus find

\[
\tilde{E}(T) = \int_{\mathbb{R}} \chi(x) \tilde{e}(x, T) dx \geq \gamma_1 \epsilon^{-1} \int_{I(x_0, T)} \left( u_x^2 + v v_x^2 + \rho^2 \right) dx.
\]

\((4.13)\)

Combining \((4.10), (4.12)\) and \((4.13)\), we obtain

\[
\int_{I(x_0, T)} \left( u_x^2 + v v_x^2 + \rho^2 \right) dx \leq \frac{\epsilon C_5}{\gamma_1 T} \pi R^3 (C_0 T)^{1/2},
\]

and taking the supremum over \(x_0 \in \mathbb{R}\) in the left-hand side we arrive at \((4.11)\).

\(\square\)

**Remark 4.2.** If \(1 \leq p < \infty\), the uniformly local space \(L^p_{ul}(\mathbb{R})\) is defined as the set of
all measurable functions \(f : \mathbb{R} \rightarrow \mathbb{R}\) such that

\[
\| f \|_{L^p_{ul}} := \left( \sup_{x_0 \in \mathbb{R}} \int_{|x - x_0| \leq 1} |f(x)|^p dx \right)^{1/p} < \infty;
\]

see [2] for a nice review article on uniformly local spaces. In view of \((4.1)\), the bound
\((4.11)\) implies that \(\| u_x(t) \|_{L^2_{ul}} + \| v_x(t) \|_{L^2_{ul}} + \| \rho(t) \|_{L^2_{ul}} \leq C R^{3/2} t^{-1/4}\) for all \(t \geq 1\).

This estimate is far from optimal, but it already implies that the solution \((u, v)\) converges uniformly on compact sets to the family \(\mathcal{E}\) of spatially homogeneous equilibria,
which is a nontrivial result. Using the smoothing properties of the parabolic system (3.1), it is possible to deduce analogous estimates in the uniform norm, in particular

\[ \| u_x(t) \|_{L^\infty} + \| v_x(t) \|_{L^\infty} \leq \frac{CR^{7/4}}{t^{1/4}}, \quad t \geq 2; \]  

(4.14)

see Sect. 4.3. Note also that the optimal decay rates for \( u_x, v_x \) given by Proposition 1.1 (in the particular case \( a = b \)) indicate that the left-hand side of (4.11) indeed decays like \( T^{-1/2} \) as \( T \to +\infty \), so that (4.11) is not far from optimal.

4.2. Control of the second-order derivatives

So far we only used the first term \( \tilde{E}(T) \) in the left-hand side of inequality (4.10), but the integral term involving \( \tilde{D}(t) \) is also valuable. In particular, the bounds (4.10), (4.12) together imply that \( \tilde{D}(t) \leq CR^3T^{-3/2} \) for “most” times \( t \) in the interval \([0, T]\), but that information is difficult to exploit because the exceptional times where such a bound possibly fails may depend on the translation parameter \( x_0 \in \mathbb{R} \). This difficulty is inherent to our approach, and to avoid it we extract from (4.10) a somewhat weaker estimate which is valid for all times.

To do that, we first study the linear parabolic system

\[ U_t = aU_{xx} + 2vV - U, \quad V_t = bV_{xx} + 2U - 4vV, \]  

(4.15)

which is obtained by differentiating (1.7) (where \( k = 1 \)) with respect to the space coordinate \( x \) or the time variable \( t \). In the analysis of (4.15), we consider the nonnegative function \( v(x, t) \) as given, independently of the solution \((U, V)\). The property we need is:

**Lemma 4.3.** There exists a constant \( C_7 > 0 \) depending only on the parameters \( a, b \) such that, for any \( v \in C^0([0, T], X_\omega) \) and any initial data \((U_1, V_1) \in X^2 \) at time \( t_1 \in [0, T] \), the solution \((U, V) \in C^0([t_1, T], X^2) \) of (4.15) satisfies

\[ \int_{\mathbb{R}} \chi(x) \left( 2|U(x, T)| + |V(x, T)| \right) dx \leq C_7 \int_{\mathbb{R}} \chi(x) \left( 2|U_1(x)| + |V_1(x)| \right) dx, \]  

(4.16)

where \( \chi \) is given by (4.2) with \( \epsilon > 0 \) as in (4.5).

**Proof.** Since the function \( v(x, t) \) is nonnegative, the linear system (4.15) is cooperative, so that a (component-wise) comparison principle holds as for the original system (1.7). In particular, the solution \((U, V)\) satisfies the estimates \( |U(x, t)| \leq \tilde{U}(x, t) \) and \( |V(x, t)| \leq \tilde{V}(x, t) \), where \((\tilde{U}, \tilde{V})\) denotes the solution of (4.15) with initial data \((|U_1|, |V_1|)\) at time \( t_1 \). In other words, it is sufficient to prove (4.16) for nonnegative initial data \((U_1, V_1)\), in which case the solution \((U, V)\) remains nonnegative by the maximum principle.
Fix $t_1 \in [0, T]$, $(U_1, V_1) \in X^2$, and let $(U, V) \in C^0([t_1, T], X^2)$ be the solution of (4.15) such that $(U(t_1), V(t_1)) = (U_1, V_1)$. Integrating by parts and using (4.3), we easily find

$$\frac{d}{dt} \int_\mathbb{R} \chi(2U + V) \, dx = \int_\mathbb{R} \chi(2aU_{xx} + bV_{xx}) \, dx$$

$$= \int_\mathbb{R} \chi''(2aU + bV) \, dx \leq \epsilon^2 c \int_\mathbb{R} \chi(2U + V) \, dx,$$

where $c = \max(a, b)$. This differential inequality is then integrated on the time interval $[t_1, T]$ to give (4.16) with $C_7 = \exp(ce^2T) = \exp(c/C_0)$.

Returning to the nonlinear system (3.1), we apply Lemma 4.3 to estimate first the time derivatives $u_t, v_t$, and then the quantity $\rho = u - v^2$.

**Lemma 4.4.** Under the assumption (4.1), any solution $(u, v) \in C^0([0, +\infty), X^2)$ of (3.1) with initial data $(u_0, v_0) \in X^2$ satisfies, for any $T > 0$,

$$\sup_{x \in \mathbb{R}} \int_{I(x_0, T)} \left(|u_{xx}| + |v_{xx}| + |\rho| \right)(x, T) \, dx \leq C_8 R^3 T^{-1/2},$$

(4.17)

where $I(x_0, T)$ and $R$ are as in Lemma 4.1, and the constant $C_8 > 0$ depends only on $a, b, \delta$.

**Proof.** We start from inequality (4.10), and we choose a time $t_1 \in [T/2, T]$ where the continuous function $t \mapsto t \tilde{D}(t)$ reaches its minimum over the interval $[T/2, T]$. We then have

$$\frac{t}{4} \tilde{D}(t_1) \leq \frac{1}{2T} \int_{T/2}^T t \tilde{D}(t) \, dt \leq \frac{C_5}{T} E(0), \quad \text{hence} \quad \tilde{D}(t_1) \leq \frac{8C_5}{T^2} E(0).$$

(4.18)

We recall that $\tilde{D} = \int_\mathbb{R} \chi \tilde{d}_0 \, dx$, where $\tilde{d}_0$ is defined in (3.8). Under assumption (4.1), there exists a constant $\gamma_2 > 0$ (depending only on $a, b, \delta$) such that $\tilde{d}_0 \geq \gamma_2(u_t^2 + v_t^2)$. Therefore, using Hölder’s inequality and estimate (4.18), we find

$$\int_\mathbb{R} \chi(2|u_t(t_1)| + |v_t(t_1)|) \, dx \leq \left(\int_\mathbb{R} \chi \, dx \right)^{1/2} \left(5 \int_\mathbb{R} \chi (u_t(t_1)^2 + v_t(t_1)^2) \, dx \right)^{1/2} \leq \left(\frac{5\pi}{\gamma_2 \epsilon} \right)^{1/2} \tilde{D}(t_1)^{1/2} \leq \left(\frac{5\pi}{\gamma_2 \epsilon} \right)^{1/2} \left(\frac{8C_5}{T^2} \right)^{1/2} E(0)^{1/2}.$$ 

Note that the right-hand side is of the form $CT^{-3/4} E(0)^{1/2}$, where the constant depends only on $a, b, \delta$. We now apply Lemma 4.3 to $(U, V) = (u_t, v_t)$, and we deduce from (4.12), (4.16) that

$$\int_\mathbb{R} \chi(x)(2|u_t(x, T)| + |v_t(x, T)|) \, dx \leq C T^{-3/4} E(0)^{1/2} \leq C_9 R^{3/2} T^{-1/2},$$

(4.19)
where the constant \( C_9 > 0 \) only depends on \( a, b, \delta \). Note that estimate (4.19) holds at the observation time \( T \), and not at the intermediate time \( t_1 \) on which we have poor control. Taking the supremum over \( x_0 \in \mathbb{R} \) as in Lemma 4.1, we deduce from (4.19) that

\[
\sup_{x_0 \in \mathbb{R}} \int_{I(x_0, T)} (|u_t(x, T)| + |v_t(x, T)|) \, dx \leq C_9 \, R^{3/2} \, T^{-1/2}.
\]  

(4.20)

To complete the proof of (4.17), it remains to control the quantity \( \rho = u - v^2 \), which measures the distance to the chemical equilibrium. It is straightforward to verify that \( \rho \) satisfies the evolution equation

\[
\rho_t = a \rho_{xx} - (1 + 4rv) \rho + 2(r-1)vv_t + 2av_x^2,
\]

(4.21)

where \( r = a/b \). Since \( v(x, t) \geq 0 \), the maximum principle implies that \( |\rho(x, t)| \leq \bar{\rho}(x, t) \) for all \( x \in \mathbb{R} \) and all \( t \in [0, T] \), where \( \bar{\rho} \) is the solution of the simplified equation

\[
\bar{\rho}_t = a \bar{\rho}_{xx} - \bar{\rho} + 2|r-1|\bar{v}v_t + 2v_x^2,
\]

with initial data \( \bar{\rho}(x, 0) = |\rho(x, 0)| \). If we denote \( c = 2 \max(|r-1|, a) \), we thus have

\[
\frac{d}{dt} \int_{\mathbb{R}} \chi \bar{\rho} \, dx = a \int_{\mathbb{R}} \chi'' \bar{\rho} \, dx - \int_{\mathbb{R}} \chi \bar{\rho}_t \, dx + c \int_{\mathbb{R}} \chi (|v v_t| + v_x^2) \, dx \leq (ae^2 - 1) \int_{\mathbb{R}} \chi \bar{\rho} \, dx + c \int_{\mathbb{R}} \chi (|v v_t| + v_x^2) \, dx.
\]

Integrating that inequality over the time interval \([T/2, T]\) and using the fact that, due to (4.5), the quantity \( \exp(ae^2 T) = \exp(a/C_0) \) is independent of \( T \), we obtain

\[
\int_{\mathbb{R}} \chi |\rho(T)| \, dx \leq C e^{-T/2} \int_{\mathbb{R}} \chi |\rho(T/2)| \, dx + C \int_{T/2}^T e^{-(T-t)} \int_{\mathbb{R}} \chi (|v(t)||v_t(t)| + v_x(t)^2) \, dx \, dt.
\]

The first term in the right-hand side is easily estimated by \( C e^{-T/2} R^2 T^{1/2} \). In the second term, keeping in mind that \( t \in [T/2, T] \), we can use (4.11), (4.20) to bound

\[
\int_{\mathbb{R}} \chi (|v(t)||v_t(t)| + v_x(t)^2) \, dx \leq C \left( R^{5/2} T^{-1/2} + R^3 T^{-1/2} \right).
\]

Altogether, this gives

\[
\int_{\mathbb{R}} \chi |\rho(x, T)| \, dx \leq C e^{-T/2} R^2 T^{1/2} + C \int_{T/2}^T e^{-(T-t)} R^3 T^{-1/2} \, dt \leq C R^3 T^{-1/2},
\]

hence

\[
\sup_{x_0 \in \mathbb{R}} \int_{I(x_0, T)} |\rho(x, T)| \, dx \leq C_{10} R^3 T^{-1/2}.
\]  

(4.22)

Finally, since \( au_{xx} = u_t + \rho \) and \( bv_{xx} = v_t - 2 \rho \), estimate (4.17) follows from (4.20), (4.22). \( \square \)
Remark 4.5. Estimate (4.17) implies that \( \|u_{xx}(t)\|_{L^1_{ul}} + \|v_{xx}(t)\|_{L^1_{ul}} + \|\rho(t)\|_{L^1_{ul}} \leq CR^3 t^{-1/2} \) for \( t \geq 1 \), and using parabolic smoothing one deduces that

\[
\|u_{xx}(t)\|_{L^\infty} + \|v_{xx}(t)\|_{L^\infty} + \|\rho(t)\|_{L^\infty} \leq \frac{CR^{7/2}}{t^{1/2}}, \quad t \geq 2;
\]  

(4.23)

see Sect. 4.3. However, in view of Remark 2.5, we believe that these decay rates are suboptimal. Note that the decay rates conjectured in (2.11) suggest that the left-hand side of (4.23) is \( O(t^{-1}) \) as \( t \to +\infty \), and this in turn implies that the left-hand side of (4.17) decays like \( T^{-1/2} \) as \( T \to +\infty \), indicating that estimate (4.17) is not far from optimal.

4.3. From uniformly local to uniform estimates

Lemmas 4.1 and 4.4 give apparently optimal estimates on the quantities \( u_x, v_x \) in some (time-dependent) uniformly local \( L^2 \) norm, and on \( u_{xx}, v_{xx}, \rho \) in some uniformly local \( L^1 \) norm. To conclude the proof of Proposition 1.2, it remains to convert these estimates into ordinary \( L^\infty \) bounds, as already announced in Remarks 4.2 and 4.5. The starting point is the following well-known estimate for the heat semigroup \( S(t) = \exp(t\partial_x^2) \) acting on uniformly local spaces. If \( f \in L^p_{ul}(\mathbb{R}) \) for some \( p \in [1, +\infty) \), then

\[
\|S(t)f\|_{L^\infty(\mathbb{R})} \leq C \max\{1, t^{-1/(2p)}\} \|f\|_{L^p_{ul}(\mathbb{R})}, \quad t > 0;
\]  

(4.24)

see [2, Proposition 2.1]. In particular, for short times, we have exactly the same parabolic smoothing effect for the solutions of the heat equation as in the ordinary \( L^p \) spaces. It is easy to establish a similar result for the solutions of the linearized system (4.15).

Lemma 4.6. Assume that \( (U, V) \) is a solution of (4.15), where \( \|v(t)\|_{L^\infty} \leq R \) for some \( R \geq 1 \). Given \( p \in [1, \infty) \), there exists a constant \( C_{11} \geq 1 \) depending only on \( a, b, p \) such that, for all \( t_1 > t_0 \geq 0 \) satisfying \( C_{11}R(t_1 - t_0) \leq 1 \), the following estimate holds:

\[
\|U(t)\|_{L^\infty} + \|V(t)\|_{L^\infty} \leq \frac{C_{11}}{(t-t_0)^{1/(2p)}} \left( \|U(t_0)\|_{L^p_{ul}} + \|V(t_0)\|_{L^p_{ul}} \right), \quad t_0 < t \leq t_1.
\]  

(4.25)

Proof. Without loss of generality, we can take \( t_0 = 0 \). We denote \( W = (U, V) \) and assume that the initial data \( W_0 = (U_0, V_0) \) belong to \( L^p_{ul}(\mathbb{R})^2 \) for some \( p \in [1, +\infty) \). If we write equation (4.15) in integral form and use estimate (4.24), we easily obtain

\[
\|W(t)\|_{L^\infty} \leq \frac{C}{t^{1/(2p)}} \|W_0\|_{L^p_{ul}} + CR \int_0^t \|W(s)\|_{L^\infty} \, ds, \quad 0 < t \leq 1.
\]

Setting \( \|W\| = \sup\{t^{1/(2p)} \|W(t)\|_{L^\infty}; 0 < t \leq t_1\} \), we find \( \|W\| \leq C\|W_0\|_{L^p_{ul}} + C'Rt_1\|W\| \), for some positive constants \( C, C' \). If we now choose \( t_1 > 0 \) so that \( C'Rt_1 \leq 1/2 \), we conclude that \( \|W\| \leq 2C\|W_0\|_{L^p_{ul}} \), which is the desired estimate. \( \square \)
We first apply Lemma 4.6 to \((U, V) = (u_x, v_x)\), with \(p = 2\). As was observed in Remark 4.2, we know from (4.11) that \(\|u_t(t)\|_{L^2_{ul}} + \|v_t(t)\|_{L^2_{ul}} + \|\rho(t)\|_{L^2_{ul}} \leq CR^{3/2}t^{-1/4}\) for all \(t \geq 1\). Thus, taking \(t \geq 2\) and choosing \(t_0 = t - 1/(C_{11}R) \geq t/2\), we see that (4.25) implies estimate (4.14). Similarly, we can apply Lemma 4.6 to \((U, V) = (u_t, v_t)\), with \(p = 1\). Here, we invoke estimate (4.19), which implies that \(\|u_t(t)\|_{L^1_{ul}} + \|v_t(t)\|_{L^1_{ul}} \leq CR^{3/2}t^{-1/2}\) for all \(t \geq 1\), and choosing \(t, t_0\) as above we deduce from (4.25) that

\[
\|u_t(t)\|_{L^\infty} + \|v_t(t)\|_{L^\infty} \leq \frac{CR^2}{t^{1/2}}, \quad t \geq 2.
\]  

To control the quantity \(\rho = u - v^2\) in \(L^\infty(\mathbb{R})\), we can proceed as in the proof of Lemma 4.4. Integrating (4.21) on the time interval \([2, t]\) and using estimates (4.14), (4.26), we easily obtain

\[
\|\rho(t)\|_{L^\infty} \leq e^{-(t-2)}\|\rho(2)\|_{L^\infty} + c \int_2^t e^{-(t-s)} \left( \|v_t(s)\|_{L^\infty} + \|v_s(s)\|_{L^\infty}^2 \right) ds \\
\leq R^2 e^{-(t-2)} + C \int_2^t e^{-(t-s)} \left( \frac{R^3}{s^{1/2}} + \frac{R^{7/2}}{s^{1/2}} \right) ds \leq \frac{CR^{7/2}}{t^{1/2}}, \quad t \geq 2.
\]  

As \(au_{xx} = u_t + \rho\) and \(b v_{xx} = v_t + 2\rho\), we obtain (4.23) from estimates (4.26), (4.27). In addition, since \(|\rho(x, t)| \leq R^2\) for all \(t \geq 0\) by (2.1), we deduce from (4.27) that \(\|\rho(t)\|_{L^\infty} \leq CR^{7/2}(1 + t)^{-1/2}\) for all \(t \geq 0\), which is the second estimate in (1.10).

The only remaining step consists in improving the decay rates of the first-order derivatives \(u_x, v_x\), so as to obtain the first estimate in (1.10).

**Lemma 4.7.** Under the assumption (4.1), any solution \((u, v) \in C^0([0, +\infty), X^2)\) of (3.1) with initial data \((u_0, v_0) \in X^2_+\) satisfies, for any \(T > 0\),

\[
\|u_x(t)\|_{L^\infty} + \|v_x(t)\|_{L^\infty} \leq \frac{C_{12}R^{7/2}}{t^{1/2}} \log(2 + t), \quad t > 0,
\]  

where \(R = 1 + \|u_0\|_{L^\infty} + \|v_0\|_{L^\infty}\) and the constant \(C_{12}\) depends only on \(a, b, \delta\).

**Proof.** Since \(u_t = au_{xx} - \rho\), we have the integral representation

\[
u_x(t) = \partial_x S(at/2)u(t/2) - \int_{t/2}^t \partial_x S(a(t-s))\rho(s) ds, \quad t > 0,
\]  

where \(S(t) = \exp(t \partial_x^2)\) is the heat semigroup. The first term in the right-hand side is easily estimated (see, e.g., [2, Corollary 2.3]):

\[
\|\partial_x S(at/2)u(t/2)\|_{L^\infty} \leq \frac{C}{t^{1/2}} \|u(t/2)\|_{L^\infty} \leq \frac{CR}{t^{1/2}}.
\]  

To bound the integral term in (4.29), we distinguish two cases, according to whether \(s \geq t - 1\) or \(s < t - 1\) (if \(t \leq 2\), the second possibility is excluded).
In the last line, we used the assumption that $t$ is Case 1.

(4.20) that to establish Proposition 1.2 without assuming that the second component there exists $C$ on $\| t \|_{L^\infty}$, we obtain using (4.27)

\[ \| \partial_x S(a(t-s)) \rho(s) \|_{L^\infty} \leq \frac{C}{(t-s)^{1/2}} \| \rho(s) \|_{L^\infty} \leq \frac{C}{(t-s)^{1/2}} \frac{R^{7/2}}{(1+s)^{1/2}}. \]  

(4.31)

Case 2. $t \geq 2$ and $t/2 \leq s \leq t - 1$. Here, we observe that, for all $x \in \mathbb{R}$,

\[
|\partial_x S(a(t-s)) \rho(t) (x)| \leq \frac{C}{(t-s)^{1/2}} \int_{\mathbb{R}} \exp \left( -\frac{|x-y|^2}{4a(t-s)} \right) \frac{|x-y|}{t-s} |\rho(y, s)| \, dy \\
\leq \frac{C}{t-s} \int_{\mathbb{R}} \exp \left( -\frac{|x-y|^2}{5a(t-s)} \right) |\rho(y, s)| \, dy \\
\leq \frac{C}{t-s} \int_{\mathbb{R}} \frac{|\rho(y, s)|}{\cosh(\epsilon(s)|x-y|)} \, dy, \text{ where } \epsilon(s) = \frac{1}{(C_0s)^{1/2}}.
\]

In the last line, we used the assumption that $t - s \leq s$ and the fact that, for any $\gamma > 0$, there exists $C > 0$ such that $e^{-x^2} \leq C \cosh(\gamma x)^{-1}$ for all $x \in \mathbb{R}$. Now, we know from (4.20) that

\[
\sup_{x \in \mathbb{R}} \int_{\mathbb{R}} \frac{|\rho(y, s)|}{\cosh(\epsilon(s)|x-y|)} \, dy \leq C_0 R^3 s^{-1/2} \leq \frac{C R^3}{(1+s)^{1/2}},
\]

and we conclude that

\[ \| \partial_x S(a(t-s)) \rho(s) \|_{L^\infty} \leq \frac{C}{t-s} \frac{R^3}{(1+s)^{1/2}}. \]  

(4.32)

Combining (4.31) and (4.32), we can estimate the integral term in (4.29) as follows:

\[
\int_{t/2}^{t} \| \partial_x S(a(t-s)) \rho(s) \|_{L^\infty} \, ds \leq \frac{C R^{7/2}}{(1+t)^{1/2}} \int_{t/2}^{t} \min \left( \frac{1}{t-s}, \frac{1}{(t-s)^{1/2}} \right) \, ds \\
\leq \frac{C R^{7/2}}{(1+t)^{1/2}} \log(2 + t),
\]

and using in addition (4.30) we obtain the desired estimate for $\| u_x(t) \|_{L^\infty}$. The bound on $\| v_x(t) \|_{L^\infty}$ is obtained by a similar argument. \hfill $\square$

4.4. The case where $v$ is not bounded away from zero

We briefly indicate here how the arguments of Sects. 4.1–4.3 have to be adapted to establish Proposition 1.2 without assuming that the second component $v(x, t)$ of system (3.1) is bounded away from zero. As already mentioned, the idea is to use the modified EDS structures introduced in Lemma 3.4, where the additional parameter $\theta > 0$ is chosen sufficiently small depending on $a, b$. Instead of $E(t), D(t)$, we use the new integrated quantities defined by

\[
E_1(t) = \int_{\mathbb{R}} \chi(x) e_1(x, t) \, dx, \quad D_1(t) = \int_{\mathbb{R}} \chi(x) d_1(x, t) \, dx,
\]
and similarly we replace \( \tilde{E}(t), \tilde{D}(t) \) by \( \bar{E}(t), \bar{D}(t) \). It is straightforward to verify that the flux term \( f_1(x, t) \) in (3.9) still satisfies the bound \( f_1^2 \leq C_0 e^{l_1} \) for some \( C_0 > 0 \), so that inequality (4.6) holds for the new quantities \( E_1(t), D_1(t) \) with the same proof. Similarly, the additional flux term \( \theta w \) in (3.11) is harmless, because

\[
(w_x w_t)^2 = w_x^2 (b w_{xx} + 2(a - b)u_{xx})^2 \leq C \tilde{e}_1 \tilde{d}_1,
\]

for some constant \( C > 0 \). As a consequence, the crucial inequality (4.10) holds for the integrated quantities \( \tilde{E}_1(t), \tilde{D}_1(t) \) by the same argument. In view of the improved lower bounds (3.12), the conclusion of Lemma 4.1 is strengthened as follows:

\[
\sup_{x_0 \in \mathbb{R}} \int_I(x_0, T) \left( u_x^2 + (1 + v)v_x^2 + \rho^2 \right) (x, T) \, dx \leq C_6 R^3 T^{-1/2},
\]

for some constant \( C_6 > 0 \) depending only on \( a, b, \theta \). Similarly, Lemma 4.4 holds without assuming (4.1) and with the stronger conclusion

\[
\sup_{x_0 \in \mathbb{R}} \int_I(x_0, T) \left( |u_{xx}| + (1 + v)|v_{xx}| + |\rho| \right) (x, T) \, dx \leq C_8 R^3 T^{-1/2},
\]

where the constant \( C_8 \) only depends on \( a, b, \theta \). The rest of the proof of Proposition 1.2 does not rely on assumption 4.1 and follows exactly the same lines as in Sect. 4.3.

5. Stability analysis of spatially homogeneous equilibria

In this section, we study the solutions of system (1.7) in a neighborhood of a spatially homogeneous equilibrium \( (\bar{u}, \bar{v}) \) with \( \bar{u} = \bar{v}^2 \) and \( \bar{v} > 0 \). We look for solutions in the form

\[
u(x, t) = \bar{u} (1 + 4 \bar{u}(x, t)) \quad \text{and} \quad v(x, t) = \bar{v} (1 + 2 \bar{v}(x, t)),
\]

so that the perturbations \( \tilde{u}, \tilde{v} \) satisfy the system

\[
\tilde{u}_t(x, t) = a \tilde{u}_{xx}(x, t) + k_1 (\tilde{v}(x, t) - \bar{u}(x, t) + \bar{v}(x, t)^2),
\quad \tilde{v}_t(x, t) = b \tilde{v}_{xx}(x, t) + k_2 (\tilde{u}(x, t) - \bar{v}(x, t) - \bar{v}(x, t)^2),
\]

(5.1)

where \( k_1 = k \) and \( k_2 = 4k \bar{v} \). We introduce the matrix notation

\[
W = \begin{pmatrix} W_1 \\ W_2 \end{pmatrix} = \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix}, \quad \mathcal{N} = \begin{pmatrix} -1 \\ 1 \end{pmatrix}, \quad \mathcal{M} = \begin{pmatrix} k_1 \\ -k_2 \end{pmatrix}, \quad D = \begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix},
\]

so that (5.1) takes the simpler form

\[
\tilde{W}_t = DW_{xx} + (\mathcal{N} \cdot W + W_2^2) \mathcal{M}.
\]

(5.2)

Note that the reaction terms in (5.2) are always proportional to the vector \( \mathcal{M} \), which therefore spans the “stoichiometric subspace” of the chemical reaction. They vanish.
when $\mathcal{N} \cdot W + W_2^2 = 0$, so that the tangent space to the manifold $\mathcal{E}$ of equilibria at the origin $W = 0$ is orthogonal to the vector $\mathcal{N}$.

The integral equation associated with (5.2) is

$$W(t) = S(t) \ast W_0 + \int_0^t S(t - s) \mathcal{M} \ast W_2(s)^2 \, ds, \quad t > 0,$$

where $\ast$ denotes the convolution with respect to the space variable $x \in \mathbb{R}$, and $S(t) = S(\cdot, t)$ is the matrix-valued function defined by

$$S(x, t) = \frac{1}{2\pi} \int_{\mathbb{R}} \exp(tA(\xi)) e^{i\xi x} \, d\xi, \quad x \in \mathbb{R}, \quad t > 0,$$

with

$$A(\xi) = -D\xi^2 + \mathcal{M} \mathcal{N}^T = \begin{pmatrix} -k_1 - a\xi^2 & k_1 \\ k_2 & -k_2 - b\xi^2 \end{pmatrix}.$$  

The exponential in (5.4) can be computed explicitly. For that purpose, it is convenient to introduce the notation

$$\mu = \frac{a + b}{2}, \quad \nu = \frac{a - b}{2}, \quad \kappa = \frac{k_1 + k_2}{2}, \quad \ell = \frac{k_1 - k_2}{2},$$

so that $a = \mu + \nu, b = \mu - \nu, k_1 = \kappa + \ell, k_2 = \kappa - \ell$. We observe that

$$A(\xi) = -(\kappa + \mu\xi^2)I + B(\xi), \quad \text{where} \quad B(\xi) = \begin{pmatrix} -\ell - \nu\xi^2 & k_1 \\ k_2 & \ell + \nu\xi^2 \end{pmatrix}.$$  

Moreover, $B(\xi)^2 = \Delta(\xi)^2 I$, where $I$ is the identity matrix and

$$\Delta(\xi) = \sqrt{\kappa^2 + 2\ell\nu\xi^2 + \nu^2\xi^4} = \sqrt{k_1k_2 + (\ell + \nu\xi^2)^2}.$$  

In particular, the eigenvalues of $A(\xi)$ are real and equal to $\lambda_{\pm}(\xi) = -(\kappa + \mu\xi^2) \pm \Delta(\xi)$.

Using these observations, it is easy to verify that

$$\exp(tA(\xi)) = e^{-(\kappa + \mu\xi^2)t} \left( \cosh(\Delta(\xi)t) I + \frac{\sinh(\Delta(\xi)t)}{\Delta(\xi)} B(\xi) \right), \quad t \geq 0.$$  

The following result specifies the decay rate of the kernel $S(\cdot, t)$ in $L^1(\mathbb{R})$ as $t \to +\infty$.

**Proposition 5.1.** For any integer $m \in \mathbb{N}$, there exists a constant $C > 0$ such that the matrix-valued function $S(\cdot, t)$ defined by (5.4) satisfies, for all $t > 0$, the estimates

$$\|\partial_x^m S(t)\|_{L^1(\mathbb{R})} \leq Ct^{-m/2},$$

$$\|\partial_x^m S(t) \mathcal{M}\|_{L^1(\mathbb{R})} \leq Ct^{-m/2}(e^{-2xt} + |\nu|t^{-1}),$$

$$\|\partial_x^m \mathcal{N}^T S(t)\|_{L^1(\mathbb{R})} \leq Ct^{-m/2}(e^{-2xt} + |\nu|t^{-1}),$$

$$\|\partial_x^m \mathcal{N}^T S(t) \mathcal{M}\|_{L^1(\mathbb{R})} \leq Ct^{-m/2}(e^{-2xt} + \nu^2 t^{-2}).$$
Proof. The following interpolation estimate will be repeatedly used: if \( f : \mathbb{R} \rightarrow \mathbb{C} \) is integrable and if the Fourier transform \( \hat{f} \) belongs to the Sobolev space \( H^1(\mathbb{R}) \), then
\[
\| f \|_{L^1}^2 \leq C \| f \|_{L^2} \| xf \|_{L^2} \leq C \| \hat{f} \|_{L^2} \| \partial_\xi \hat{f} \|_{L^2}.
\] (5.9)

Of course, inequality (5.9) remains valid if \( f \) is vector-valued or matrix-valued. Given any \( t > 0 \), we first apply (5.9) to \( f(x) = S(x, t) \), recalling that \( \hat{S}(\xi, t) = \exp(tA(\xi)) \) is given by (5.7). Without loss of generality, we assume henceforth that \( a \geq b \), so that \( \nu \geq 0 \) (the converse case is completely similar). Using the elementary bounds
\[
\max\left(\sqrt{k_1k_2}, |\ell + \nu \xi^2|\right) \leq \Delta(\xi) \leq \kappa + \nu \xi^2,
\]
as well as \( \cosh(z) \leq e^z \) and \( \sinh(z) \leq \min(1, z) e^z \) for \( z \geq 0 \), we easily deduce from (5.7) the pointwise estimates
\[
|\partial_\xi \hat{S}(\xi, t)| \leq C e^{-b \xi^2 t}, \quad |\partial_\xi \hat{S}(\xi, t)| \leq C |\xi| |t| e^{-b \xi^2 t},
\] (5.10)
which imply that \( \| \partial_\xi \hat{S}(t) \|_{L^2} \leq C t^{-1/4} \) and \( \| \partial_\xi \hat{S}(t) \|_{L^2} \leq C t^{1/4} \). It thus follows from (5.9) that the \( L^1 \) norm of \( S(t) \) is uniformly bounded for all \( t > 0 \). Similarly, for any \( m \in \mathbb{N} \), the bounds (5.10) imply that \( \| \hat{S}^m(t) \|_{L^2} \leq C t^{-1/4 - m/2} \) and \( \| \partial_\xi \hat{S}^m(t) \|_{L^2} \leq C t^{1/4 - m/2} \), so that (5.9) gives the first inequality in (5.8).

The other inequalities in (5.8) exploit cancellations that occur when the matrix \( S(x, t) \) acts on the vector \( \mathcal{M} \) (to the right) or on the vector \( \mathcal{N}^T \) (to the left). We start from the identities
\[
B(\xi) \mathcal{M} = -\kappa \mathcal{M} - \nu \xi^2 \begin{pmatrix} k_1 \\ k_2 \end{pmatrix}, \quad \mathcal{N}^T B(\xi) = -\kappa \mathcal{N}^T + \nu \xi^2 \begin{pmatrix} 1 & 1 \end{pmatrix},
\] (5.11)
which follow immediately from the definitions. Writing \( \cosh(\Delta t) = e^{-\Delta t} + \sinh(\Delta t) \) in (5.7), we find
\[
\hat{S}(\xi, t) \mathcal{M} = e^{-\kappa t + \mu \xi^2 t} \begin{pmatrix} e^{-\Delta t} \mathcal{M} + \left(1 - \frac{\kappa}{\Delta}\right) \sinh(\Delta t) \mathcal{M} - \nu \xi^2 \frac{\sinh(\Delta t)}{\Delta} \begin{pmatrix} k_1 \\ k_2 \end{pmatrix} \end{pmatrix}.
\] (5.12)

In the particular case where \( \nu = 0 \), one has \( \Delta = \kappa \), so that \( \hat{S}(\xi, t) \mathcal{M} = e^{-\kappa t + \mu \xi^2 t} \mathcal{M} \). In general, only the first term in the right-hand side of (5.12) decays exponentially in time, and can be estimated using the elementary bound \( \mu \xi^2 + \Delta(\xi) \geq \kappa + b \xi^2 \). The remaining terms are treated as above, and we arrive at pointwise estimates of the form
\[
|\hat{S}(\xi, t) \mathcal{M}| \leq e^{-\kappa t + b \xi^2 t} + C \nu \xi^2 e^{-b \xi^2 t},
\]
\[
|\partial_\xi \hat{S}(\xi, t) \mathcal{M}| \leq C |\xi| |t| e^{-\kappa t + b \xi^2 t} + C \nu |\xi| (1 + \xi^2 t) e^{-b \xi^2 t}.
\]

Invoking (5.9), we thus obtain the second inequality in (5.8). The third one is obtained similarly, starting from the second relation in (5.11).
Finally, a straightforward calculation shows that
\[
\mathcal{N}^T \dot{S}(\xi, t) \mathcal{M} = -2 e^{-\left(\kappa + \mu \xi^2\right)t} \left\{ \kappa e^{-\Delta t} + \left( \kappa - \frac{\kappa^2 + \ell v \xi^2}{\Delta} \right) \sinh(\Delta t) \right\},
\]
and we deduce the pointwise estimates
\[
|\mathcal{N}^T \dot{S}(\xi, t) \mathcal{M}| \leq C e^{-2\kappa t} + C v^2 \xi^4 e^{-b \xi^2 t},
\]
\[
|\partial_\xi \mathcal{N}^T \dot{S}(\xi, t) \mathcal{M}| \leq C|\xi| t e^{-2\kappa t} + C v^2 |\xi|^3 (1 + \xi^2 t) e^{-b \xi^2 t}.
\]
Using again (5.9), we obtain the last inequality in (5.8).

The conclusion of Proposition 5.1 is interesting for at least two reasons. First, if \(a \neq b\) and if \(W(t) = S(t) * W_0\) is a solution of the linearized equation (5.2) with initial data \(W_0 \in X^2\), the first inequality in (5.8) (with \(m = 1\)) and the third one (with \(m = 0\)) imply that
\[
\|\tilde{u}_x(t)\|_{L^\infty} + \|\tilde{v}_x(t)\|_{L^\infty} = O(t^{-1/2}), \quad \|\tilde{u}(t) - \tilde{v}(t)\|_{L^\infty} = O(t^{-1}), \quad (5.13)
\]
as \(t \to +\infty\). We emphasize that, at the linear level, the difference \(\tilde{u} - \tilde{v}\) measures the distance to the manifold \(\mathcal{E}\) of equilibria. Because of (5.13), we conjecture that the decay rates in (1.8) are optimal for general solutions of (1.7); see the discussion after Proposition 1.2. Note that Proposition 1.1 assumes that the diffusivities are equal, in which case Proposition 5.1 shows that the difference \(\tilde{u}(t) - \tilde{v}(t)\) decays exponentially fast as \(t \to +\infty\) when \(W = (\tilde{u}, \tilde{v})\) solves the linearized equation.

The second observation concerns the full, nonlinear equation (5.2). Using the first two estimates in (5.8), it is easy to prove by a fixed point argument that the Cauchy problem for (5.2) is globally well posed for small data \(W_0 \in L^p(\mathbb{R})^2\) if \(p < \infty\), and that the solutions satisfy \(\|W(t)\|_{L^\infty} = O(t^{-1/(2p)})\) as \(t \to +\infty\). However, the critical case \(p = \infty\), which is relevant in the context of the present paper, cannot be treated by this approach. In fact, using the optimal decay estimates listed in Proposition 5.1, we are not even able to show that the solution \(W(t)\) of (5.2) originating from small initial data \(W_0 \in X^2\) stays uniformly bounded for all times, except in the case of equal diffusivities where the problem is much simpler. The reason is that, if \(a \neq b\), the quantity \(\|S(t)\mathcal{M}\|_{L^1(\mathbb{R})}\) decays like \(t^{-1}\) as \(t \to +\infty\) and is therefore not integrable in time. This indicates that the dynamics of system (1.7) in the space of bounded functions on \(\mathbb{R}\) is not simple to analyze, even in a neighborhood of a spatially homogeneous equilibrium.

6. Conclusion and perspectives

The present work is only a modest incursion into the realm of extended reaction–diffusion systems with a local gradient structure. Even for the very simple example (1.7), which has many specific properties, our results are incomplete and a global
understanding of the dynamics is still missing. To be more precise, assume that the decay rates (2.11) hold for all bounded and nonnegative solutions of (1.7), which is a reasonable conjecture (although we are not able to prove that when $a \neq b$). The quantity $\rho = u - v^2$, which measures the distance to the manifold $E$ of equilibria, satisfies the equation

$$\rho_t = a \rho_{xx} - k(1+4v)\rho + 2(a-b)uv_{xx} + 2av_x^2. \quad (6.1)$$

According to (2.11), the last three terms in (6.1) decay like $t^{-1}$ when $t \to +\infty$, whereas $\rho_{xx} = \mathcal{O}(t^{-2})$. It is therefore reasonable to expect that

$$\rho = \frac{1}{k(1+4v)}(2(a-b)uv_{xx} + 2av_x^2) + \mathcal{O}(t^{-2}), \quad t \to +\infty. \quad (6.2)$$

Inserting this ansatz into the $v$-equation $v_t = bv_{xx} + 2k\rho$ and neglecting the higher-order terms, we obtain the following quasilinear diffusion equation

$$v_t = b + 4av \quad v_{xx} + \frac{4a}{1+4v} v_x^2, \quad x \in \mathbb{R}, \quad t > 0. \quad (6.3)$$

Alternatively, setting $w = v + 2v^2$, we can write (6.3) in the more elegant form

$$w_t = (D(w)w_x)_x, \quad \text{where} \quad D(w) = a + \frac{b-a}{\sqrt{1+8w}}. \quad (6.4)$$

We conjecture that the longtime asymptotics of any solution of (1.7) in $X^2_+$ corresponds to a slow motion along the manifold $E$ of chemical equilibria, which is described to leading order by the diffusion equation (6.3) or (6.4). Note that the effective diffusion $D(w)$ in (6.4) depends on the solution $w$ in a nontrivial way, except in the particular case $a = b$ where (6.4) reduces to the linear heat equation. Given two positive constants $w_\pm$, one can solve the Cauchy problem for (6.4) with Riemann-like initial data

$$w_0(x) = \begin{cases} w_- & \text{if } x < 0, \\ w_+ & \text{if } x > 0, \end{cases}$$

and this produces a self-similar solution of (6.4) which should describe the diffusive mixing of two chemical equilibria under the dynamics of (1.7); see [18] for a similar result in the context of the Ginzburg–Landau equation. A rigorous justification of the slaving ansatz (6.2) and of the relevance of the diffusion equation (6.4) for the longtime asymptotics of the original system (1.7) is left to a future work.

On the other hand, the model we consider is just a simple example in a rich family, and it is natural to ask to which extent our analysis relies on specific features of (1.7). In a first step toward greater generality, we consider the reaction $nA \rightleftharpoons mB$, where $n, m$ are positive integers such that $n + m \geq 3$. The corresponding system

$$u_t = au_{xx} + nk(u^m - u^n), \quad v_t = bv_{xx} + mk(u^n - v^m), \quad (6.5)$$
is still cooperative, and the analogue of Proposition 2.1 holds. It is also possible to find a polynomial EDS structure of the form (3.2), which reads

\[ e = \frac{1}{n(n+1)} u^{n+1} + \frac{1}{m(m+1)} v^{m+1}, \]

\[ f = \frac{a}{n} u^n u_x + \frac{b}{m} v^m v_x, \]

\[ d = au^{n-1}u_x^2 + bv^{m-1}v_x^2 + (u^n - v^m)^2. \]

However, there is apparently less flexibility for constructing a second EDS structure in the sense of Sect. 3, and at the moment we can do that only if the ratio \( a/b \) is not too different from 1. Except for that limitation in the choice of the parameters \( a, b \), the analogue of Proposition 1.2 holds with a similar proof.

The situation changes significantly when we turn our attention to more realistic chemical reactions such as

\[ A_1 \rightleftharpoons A_2 + A_3. \]

The associated system is still relatively simple

\[ u_t = au_{xx} - u + vw, \quad v_t = bv_{xx} + u - vw, \quad w_t = cw_{xx} + u - vw, \quad (6.6) \]

but new difficulties arise that make the analysis substantially more difficult. First, system (6.6) is not cooperative and does not satisfy any comparison principle we know of. As a consequence, new arguments are needed to show that the solutions of (6.6) stay uniformly bounded for all nonnegative initial data in \( L^\infty(\mathbb{R}) \). For the same reason, it is not obvious that a solution starting close (in the \( L^\infty \) sense) to a chemical equilibrium will stay in a neighborhood of that equilibrium for all times. Next, the only EDS structure we are aware of is given by the general formulas (1.5), and we are not able to construct a second EDS structure that controls the entropy dissipation, as we did in Sect. 3 for the simpler system (1.7). At the moment, we are thus unable to prove the analogue of Proposition 1.2 for system (6.6), and a fortiori for more complex reaction–diffusion systems of the form (1.2). We hope to be able to elucidate some of these questions in the future.

A. Flux bound for the Boltzmann entropy

We show here that the quantities $e$, $f$, $d$ defined in (1.5) satisfy the pointwise estimate

$$|f(x, t)|^2 \leq C e(x, t) d(x, t) \log(2 + e(x, t)),$$

(A.1)

where $C = C_* \max(d_1, \ldots, d_n)$ and

$$C_* = \sup_{z > 0, z \neq 1} \frac{z \log(z)^2}{\phi(z) \log(2 + \phi(z))}, \quad \phi(z) = z \log(z) - z + 1.$$

Indeed, using the definitions of $f$ and $d$ in (1.5) and Hölder’s inequality, we find

$$|f|^2 \leq \left( \sum_{i=1}^n d_i |\nabla c_i|^2 \right) \left( \sum_{i=1}^n d_i c_i (\log(c_i))^2 \right) \leq d \left( \sum_{i=1}^n d_i c_i (\log(c_i))^2 \right).$$

On the other hand, we have

$$\sum_{i=1}^n c_i (\log(c_i))^2 \leq C_* \sum_{i=1}^n \phi(c_i) \log(2 + \phi(c_i)) \leq C_* e \log(2 + e),$$

where $e = \sum_{i=1}^n \phi(c_i)$. Altogether, this gives (A.1). Numerically, one finds $C_* \approx 3.06$.
