Axion mass in antiferromagnetic insulators

Koji Ishiwata

(Dated: July 12, 2021)

We calculate axion potential in antiferromagnetic insulators from path integral. It is derived from the effective potential for the order parameter of the antiferromagnetic phase in insulators. Static and dynamical axions are defined consistently from the potential. Consequently antiferromagnetic/paramagnetic and topological/normal orders are classified. The dynamical axion is predicted in all phases and its mass turns out to be various values up to eV scale.

I. INTRODUCTION

Axion is a hypothetical elementary particle that is considered to solve the strong CP problem in QCD [1]. It is originally massless due to shift symmetry of the Lagrangian, and it becomes massive after the QCD transition via a nonperturbative effect. Other than the QCD axion, axion particles are known to emerge from superstring theory. Motivated partly by that, axion-like particles (ALPs) are studied in phenomenological, astrophysical, and cosmological contexts. The mass of ALPs is usually considered as a free parameter, leading to more rich phenomenology compared to the QCD axion (see, e.g., Ref. [2] for review).

Besides in the field of particle physics, axion is discussed in condensed matter physics. For example, the magnetoelectric response due to $E \cdot B$ coupling ($E$ and $B$ are electric and magnetic fields, respectively) is already known, and the $E \cdot B$ coupling is the interaction term of axion with the gauge field. Therefore, such magnetoelectric response may be understood in terms of “axion.” There have been several studies in that context so far. Different from axion in elementary particle physics, there are two types of “axions” in condensed matter physics: static axion and dynamical axion. (Hereafter we use “axion” as an axion in condensed matter physics unless otherwise mentioned.) In terms of Lagrangian, they are written as

$$\mathcal{L}_\theta = \frac{\alpha}{\pi} (\theta_0 + a) E \cdot B,$$  \hspace{1cm} (1)

where $\alpha = e^2/(4\pi)$ is the fine-structure constant and we have denoted $\theta_0$ as the static axion (constant) and $a$ as the dynamical axion. The former is pointed out by Refs. [3–8] as the $E \cdot B$ coupling. Nonzero $\theta_0$ breaks both time-reversal $T$ and parity $P$. However, when $\theta_0 = \pi$ those symmetries are intact. This nontrivial state is known as an topological state. Ref. [9], on the other hand, studied the latter to predict that the dynamical axion causes the total reflection of light irradiated to the topological insulators under an antiferromagnetic (AFM) order. They solved equations of motion of photon and the dynamical axion that interact with each other via the $E \cdot B$ interaction term and found an energy gap emerged in the topological insulators. In the similar context, Ref. [10] shows that an electric field is expected to be converted to a magnetic field due to the dynamical axion when the electric field exceeds certain critical value. (See also Refs. [11–15].) Such recent developments in both particle physics and condensed matter physics have motivated particle axion and ALPs search by using axions in insulators [16–19].

In this paper we calculate the effective potential for the order parameter of the AFM phase from the partition function of the system defined by the path integral. Using the effective potential, axion potential is derived. It is found that the effective potential and axion potential are intuitive and useful in order to distinguish the AFM/paramagnetic (PM) order and the topological/normal phase depending on the model parameters. We clarify the static and dynamical axions in the AFM insulators and how they are related to the AFM order and the topological state. Consequently, the mass of dynamical axion is determined. While it is estimated to be $O$(meV) in Ref. [9], the axion mass turns out to be larger up to $O$(eV) or a much suppressed value depending on the property of insulators.

This paper is organized as follows. In Sec. II, the effective potential for order parameter of the AFM phase is derived. Using the result, the AFM/PM phases are determined. The effective potential is interpreted in terms of axion field and axion potential is derived in Sec. III. Sec. IV contains conclusions and discussion.

II. POTENTIAL OF ANTIFERROMAGNETIC ORDER PARAMETER

The topological state in insulators is considered to be realized by a (quasi) gapless state via the spin-orbit coupling. For modeling such a state, a minimum setup is to consider 4-by-4 matrix, i.e., two energy states (or orbits or sublattices) with up and down spins. Such a model is often described by the gamma matrices (even in lower or higher dimension space [3]). In the momentum space, it is given by

$$H(k) = \epsilon_0(k) \mathbf{1}_{4 \times 4} + \sum_{a=1}^{5} d^a(k) \Gamma^a,$$ \hspace{1cm} (2)
where \( k = (k_x, k_y, k_z) \) is the wavenumber and \( \Gamma^a \) are the gamma matrices satisfying
\[
\{\Gamma^a, \Gamma^b\} = 2\delta^{ab} 1_{4 \times 4}, \quad \text{tr}(\Gamma^a \Gamma^b) = 4\delta^{ab}, \quad \text{tr}(\Gamma^a) = 0.
\] (3) (4)

The representation of the gamma matrices depends on the basis. In Refs. [9, 20], for example, the basis of the antibonding and bonding are chosen, i.e., \(|P_{1+} \Gamma, \sigma\rangle, |P_{2-} \Gamma, \sigma\rangle\) \((\sigma = \uparrow, \downarrow)\):
\[
\Gamma^a = (\sigma^x \otimes s^x, \sigma^x \otimes s^y, \sigma^y \otimes 1, \sigma^z \otimes 1, \sigma^x \otimes s^z), \quad (5)
\]
where \(\sigma^j\) and \(s^j\) \((j = x, y, z)\) are the Pauli matrices. The coefficients \(d^a\) on the other hand, are given by theoretical model and/or the first-principles computation. Among models, the so-called Dirac model is a low energy effective model to describe the topological insulators expanding a Hamiltonian around a Dirac point. In the Dirac model, \(d^a\) are given as
\[
(d^1, d^2, d^3, d^4, d^5) = (A k_x, A k_y, A k_z, m + B k^2, m_5), \quad (6)
\]
where \(k^2 = |k|^2\) and the gamma matrices are given in Eq. (5). \(\epsilon_0, A, B, m, \) and \(m_5\) have a mass dimension of one. \(\epsilon_0\) is not important in our later discussion, which is explained in Appendix C.) The Dirac model can be derived from a certain model, such as an extended Fu-Kane-Mele-Hubbard model on a diamond lattice at half-filling, discussed in Refs. [19, 21], or the first-principles calculation of the layered, stoichiometric crystals \(\text{Sr}_2 \text{Te}_3\), \(\text{Sr}_2 \text{Se}_3\), \(\text{Bi}_2 \text{Te}_3\) and \(\text{Bi}_2 \text{Se}_3\) [20]. In general, the coefficient \(A\) corresponds to the spin-orbit coupling.\(^1\) If it is zero, then \(\theta\) is exactly zero and no topological phase appears, which will be easily understood from Eq. (28). The coefficient \(m\) and \(B\) describe the energy gap. They originate in, for instance, the spin-orbit coupling [20], or hopping strength anisotropy due to the lattice distortion in the diamond lattice [21]. \(m\) (and \(B\)) effectively determines whether the insulator is topological or normal. Namely, \(m/B < 0\) \((m/B > 0)\) corresponds to the topological (normal) state for \(B \neq 0\). When \(B = 0\), negative \((positive)\) \(m\) gives the topological \((normal)\) state. Finally \(m_5\) is an order parameter of the AFM phase and plays an important role for describing axion in insulators, which will be discussed in detail soon.

While in the numerical study we adopt the Dirac model, the following analytical calculation is applied for generic model described by Eq. (2). Besides, in Appendix A we give another numerical results in the effective model for 3D topological insulators given in Eq. (A1) [9].

\(^1\) To be precise, the spin-orbit interaction itself is local and it is constant in momentum space. The momentum dependence comes from nonlocal interaction coupled to spin-orbit coupling.

The \(m_5 \Gamma^5\) term appears due to the Hubbard-Stratonovich transformation or the mean field approximation of the Hubbard interaction term, which causes the AFM order written in a sublattice basis \(|A, \sigma\rangle, |B, \sigma\rangle\),
\[
\mathcal{H}_{\text{int}} = \frac{UV}{N} \int d^3 x \left( n_{A \uparrow} n_{A \downarrow} + n_{B \uparrow} n_{B \downarrow} \right) , \quad (7)
\]
where \(n_{A \sigma} = \psi^\dagger_{A \sigma} \psi_{A \sigma}\) and \(n_{B \sigma} = \psi^\dagger_{B \sigma} \psi_{B \sigma}\) are number density of electron with spin \(\sigma = \uparrow, \downarrow\) at sublattice \(A\) and \(B\), respectively. \(U\) is a parameter with mass dimension one, \(V\) is the volume of the material and \(N\) is the number of sublattice \(A\) \((B)\) in the material. This interaction term involves four electrons and it is difficult to analyze. However, it can be rewritten by the Hubbard-Stratonovich transformation with introducing a scalar field \(\phi\) in the path integral. (See Appendix B for details.) As a result, the interaction term becomes
\[
\exp \left[ -i \int dt \mathcal{H}_{\text{int}} \right] = \int \mathcal{D} \phi \exp \left\{ -i \int d^4 x \left[ M^2 \phi^2 + \phi(n_{A \uparrow} - n_{B \uparrow}) \right] + \cdots \right\} , \quad (8)
\]
where \(n_{i \uparrow} - n_{i \downarrow}\) \((i = A, B)\), and
\[
M^2 = \int \frac{d^3 k}{(2 \pi)^3} \frac{2}{U} . \quad (9)
\]
Here the momentum integral is executed in the first Brillouin zone unless otherwise mentioned, which is applied to other momentum integral in the later discussion. The term proportional to \(n_{A \uparrow} - n_{B \uparrow}\) gives \(m_5 \Gamma^5\) term in the sublattice basis. (See Appendix D for the explicit expression of \(\Gamma^a\).) Here we have renamed \(m_5\) as
\[
\phi \equiv m_5 . \quad (10)
\]
When \(m_5 = 0\) the Hamiltonian is \(\mathcal{T}\) and \(\mathcal{P}\) conserving while a finite value of \(m_5\) breaks both. In addition, it should be noticed that the mass term for \(\phi\) emerges, which must be included in the effective Lagrangian for \(\phi\).

For later convenience we separate the Hamiltonian as
\[
H(k) = H_0(k) + \delta H(k) , \quad (11)
\]
where
\[
H_0(k) = \epsilon_0(k) 1_{4 \times 4} + \sum_{a=1}^4 d^a_0(k) \Gamma^a , \quad (12)
\]
\[
\delta H(k) = m_5 \Gamma^5 . \quad (13)
\]
Here \(d^a_0\) is defined by
\[
d^a_0 = (d^1, d^2, d^3, d^4, 0) . \quad (14)
From the Hamiltonian, the partition function is defined by functional integral of four-component electron field $\psi$ and $\phi$,

$$Z = \int \mathcal{D}\psi \mathcal{D}\psi^\dagger \exp i S + i S_\phi^\text{mass},$$  \hspace{1cm} (15)

where

$$S = \int d^4 x \psi^\dagger(x) [i\partial_t - H] \psi(x),$$  \hspace{1cm} (16)

$$S_\phi^\text{mass} = -\int d^4 x M^2 \phi^2.$$  \hspace{1cm} (17)

Here $H$ is the Hamiltonian in the coordinate space. Now we integrate out $\psi$ in Eq. (15) to derive the effective Lagrangian for $\phi$. It is straightforward to get

$$Z = \int \mathcal{D}\phi \exp \left\{ i S_\phi^\text{mass} + \text{Tr} \log [-i\partial_t + H] \right\},$$  \hspace{1cm} (18)

Here “Tr” includes that trace over matrices and space-time integral. To further rewrite the above expression, let us define Green’s function as

$$G_0^{-1}(x) \equiv i\partial_t - H,$$  \hspace{1cm} (19)

where $H_0$ is $H_0(k)$ written in the coordinate space. Then, separating $H$ as $H = H_0 + \delta H$ and using

$$\log [-i\partial_t + H] = \log (G_0^{-1}) - \sum_{n=1}^\infty \frac{1}{n} (G_0\delta H)^n,$$  \hspace{1cm} (20)

we get

$$Z = \int \mathcal{D}\phi \exp \left\{ i S_\phi^\text{mass} + \text{Tr} \left[ \log (G_0^{-1}) \right] - \text{Tr} \left[ \sum_{n=1}^\infty \frac{1}{n} (G_0\delta H)^n \right] \right\}. $$  \hspace{1cm} (21)

The effective potential for $\phi$ is derived as polynomial expansion from Eq. (21). Using the Fourier transformation of the propagator,

$$G_0(x) = \int \frac{d^4 k}{(2\pi)^4} \tilde{G}_0(k) e^{-ik\cdot x},$$  \hspace{1cm} (22)

$$\tilde{G}_0(k) = \frac{k^0 - \epsilon_0(k) + \sum_{a=1}^4 d_0^a(k) \Gamma^a}{(k^0 - \epsilon_0(k))^2 - |d_0(k)|^2},$$  \hspace{1cm} (23)

where $k \cdot x = k^0 x^0 - k \cdot x$ and $|d_0(k)|^2 \equiv \sum_{a=1}^4 d_0^a d_0^a$, it is obtained as (see Appendix C for detail)

$$V_\phi = -2 \int \frac{d^3 k}{(2\pi)^3} (|d_0|^2 + \phi^2 - |d_0|) + M^2 \phi^2.$$  \hspace{1cm} (24)

A similar calculation is done in Refs. [15, 18, 22]. However, the expansion is truncated at $n = 2$. On top of that, the mass term, the second term in Eq. (24) is missing.\(^2\)

In fact, both the negative term derived from the last term in Eq. (21) and the mass term are crucial to understand the AFM/FM phase and the topological/normal state, which will be shown below.

Fig. 1 shows $V_\phi(\phi)$ as function of $\phi$. In the calculation we introduce dimensionless wavenumber $\tilde{k} \equiv ka$ where $a$ is the lattice size (typically $A$) and $B/a^2 = 0.5$ eV\(^3\) and the integral is executed in $[-1, 1]$ region. This is because the Dirac model is low energy effective model and the (normalized) momentum cannot take as large as $\pi$. (Instead if the effective model for 3D topological insulators given in Ref. [9] is used, then the momentum integral is done in $[-\pi, \pi]$. See Appendix A for the results.) It is seen that the curvature at $\phi = 0$ becomes negative when $U$ gets larger. This situation can be understood by expanding $V_\phi$ around $\phi = 0$,

$$V_\phi = \int \frac{d^3 k}{(2\pi)^3} \left[ \frac{2}{U} \frac{1}{|d_0|} \right] \phi^2 + \mathcal{O}(\phi^4),$$  \hspace{1cm} (25)

Here we have used Eq. (9). It is seen that the coefficient of $\phi^2$ term becomes negative when $U > U_{\text{crit}}$ where $U_{\text{crit}}$ satisfies

$$\int \frac{d^3 k}{(2\pi)^3} \left[ \frac{2}{U_{\text{crit}}} - \frac{1}{|d_0|} \right] = 0.$$  \hspace{1cm} (26)

Namely, for $U < U_{\text{crit}}$ the minimum of the potential located at $\phi = 0$, corresponding to the PM phase. When $U > U_{\text{crit}}$, on the other hand, the phase transition occurs to get nonzero $\phi_0$, which satisfies

$$\int \frac{d^3 k}{(2\pi)^3} \left( \frac{2}{U_{\text{crit}}} - \frac{1}{\sqrt{|d_0|^2 + \phi_0^2}} \right) = 0,$$  \hspace{1cm} (27)

and the AFM order appears. In the next section, we show how the situation is described in terms of the axion field.

### III. AXION POTENTIAL

So far we have derived the effective potential for $\phi$. It can be described by axion field because $\phi$ is related to the axion field $\theta$. To be concrete, $\theta$ is given by $d^a [9],$

$$\theta = \frac{1}{4\pi} \int \frac{d^3 k}{(|d| + d^2)^2 |d|^3} \epsilon^{ijkl} d^i \partial_k \phi d^j \partial_k \phi d^l \partial_k \phi,$$  \hspace{1cm} (28)

\(^2\) There are other typos in Ref. [22]. We thank A. Sekine for confirming this.

\(^3\) A larger value of $B$ is obtained in first-principles calculation [20]. This may indicate it is difficult to have the AFM order in the materials such as Fe-doped Bi$_2$Te$_3$ (see also later discussion). In our analysis, we choose $O(1)$ eV for $A$ and $B$. 
FIG. 1. $V_\phi$ as function of $\phi$ for various values of $m$ [eV] in Dirac model. $A/a = 1$ eV, $B/a^2 = 0.5$ eV is taken. At each panel, $U$ [eV] is taken to 1.5 to 2.5 from top line to bottom line. We put a cutoff to the normalized momentum integral as $-1 < \tilde{k} < 1$.

where $|d|^2 = \sum_{\alpha=1}^5 d^\alpha d^\alpha$ and $\epsilon^{ijkl}$ is Levi-Civita symbol with $i, j, k, l$ being $1, 2, 3, 5$. It is checked that $\theta = 0$ or $\pm \pi$ when $d^2 = \phi = 0$ and the value depends on $d^4$. (We note that $\theta = +\pi$ and $-\pi$ are identical and hereafter we focus on $\theta = \pi$ unless otherwise stated. See also Appendix D for another derivation of $\theta$ using chiral anomaly. However, it is not equivalent to the above expression, except for a specific case.) For instance, in the Dirac model given in Eq. (6), $m/B > 0$ ($< 0$) gives $\theta = 0$ ($\pi$) when $d^2 = 0$ [23]. We have confirmed that the results are consistent with Ref. [23] (see Figs. 4 and 5 in Appendix A). Using Eq. (28), we can derive $\phi$ as function of $\theta$. Let us write

$$\phi = \Phi(\theta).$$

Then, the potential as function of $\theta$ can be obtained by

$$V_\phi(\Phi(\theta)) \equiv V_\theta(\theta).$$

Fig. 2 shows $V_\theta$ as function of $\theta/(2\pi)$ in the Dirac model. It is seen the axion potential nontrivially depends on the sign of $m$. When $U$ is smaller than $U_{\text{crit}}$, the potential minimum is located at $\theta = 0$ ($\pi$) for $m > 0$ ($m < 0$). $V_\theta$ is multivalued function of $\theta$ since $\phi$ is multivalued function of $\theta$ for $m > 0$. For $m < 0$, on the other hand, $\theta$ is monovalent function, i.e., $\theta \to \pm \pi$ for $\phi \to 0 \pm$. (See Fig. 4 in Appendix A.) In terms of potential minimum of $V_\theta$, both $\theta = 0$ and $\pi$ correspond to $\phi$ (or $m_\text{crit}$) = 0, i.e., the PM phase. In terms of $\theta$, on the other hand, they are different topologically. Namely, $\theta = 0$ ($\pi$) is classified as the normal insulator (topological insulator). When $U$ gets larger than $U_{\text{crit}}$, nonzero $\phi_0$ becomes a minimum of the potential and insulator is in the AFM order. In terms of axion, both $\theta = 0$ and $\pi$ becomes unstable and a new stable point appears. It should be noticed that the effective potential given in Eq. (24) is crucial to derive this result, which consists of the negative potential term derived from integrating out the electron field and the positive mass term that comes consequently from the Hubbard-Stratonovich transformation of the Hubbard interaction term (7).

Now the definition of static and dynamical axions are clear. The static axion $\theta_0$ is defined as a stationary point of $V_\phi(\theta)$, and the dynamical axion $a$ as a fluctuation around $\theta_0$. Denoting $\phi_0$ as corresponding value of $\theta_0$, we expand $\phi$ and the potential $V_\phi$,

$$\phi = \phi_0 + \frac{d\Phi(\theta)}{d\theta} \bigg|_{\theta=\theta_0} a + \cdots,$$

$$\equiv \phi_0 + ga + \cdots,$$  \hspace{0.5cm} (31)

$$V_\phi = V_\phi(\phi_0) + \frac{1}{2} g^2 \left[ \frac{d^2 V_\phi}{d\phi^2} \right]_{\phi=\phi_0} a^2 + \cdots$$

$$\equiv V_\phi(\phi_0) + J g^2 m_\phi^2 a^2 + \cdots,$$  \hspace{0.5cm} (32)

where $g$ is the coupling constant of the axion-electron interaction term (7).
where $J$ is called stiffness and obtained as (see Appendix C for derivation)

$$J = \int \frac{d^3k}{(2\pi)^3} \frac{|d_0|^2}{4(\phi_0^2 + \phi_0^2)^{5/2}}. \quad (33)$$

Using Eqs. (31) and (32), the action for the dynamical axion $a$ is obtained,

$$S_a = Jg^2 \int d^4x \left[ -\partial^2 \phi_a + (v \cdot \nabla)^2 - m_a^2 \right] a + O(a^4). \quad (34)$$

Therefore, the axion mass is obtained by

$$Jm_a^2 = \int \frac{d^3k}{(2\pi)^3} \left[ \frac{2}{U} - \frac{1}{|d_0|} \right], \quad (35)$$

for $U < U_{\text{crit}}$

$$Jm_a^2 = \int \frac{d^3k}{(2\pi)^3} \frac{d_0^2}{|d_0| (|d_0|^2 + \phi_0^2)^{3/2}}, \quad (36)$$

for $U > U_{\text{crit}}$. Eqs. (33) and (36) are consistent with the results in Ref. [9], except for a factor of 4 larger compared to ones in the literature. In the literature, however, how the value of $\phi_0$ is determined is not clearly stated. Rather it is treated as another parameter that is independent of the model parameter in $d^a$. By using the effective potential, on the contrary, $\phi_0$ is determined uniquely as a stationary point of the potential when the model parameters are fixed.

To demonstrate the result, we plot the axion mass on phase plane in Fig. 3. There are phases classified by the AFM/PM and the topological/normal orders, and they are determined by $U$ and $m$ for the given parameters $A$ and $B$ of the Dirac model. The AFM (PM) phase corresponds to $\phi_0 = \text{nonzero} (0)$, and the topological (normal) phase corresponds to $m < 0$ ($m > 0$). In the PM phase, $\theta_0 = 0$ ($\pi$) in the normal (topological) phase meanwhile $\theta_0$ takes a value of $0 < \theta_0 < \pi$ in the AFM phase depending on $\phi_0$. It is found that the axion mass is typically $O(1)$ eV in the four phases. (The same result is obtained in the effective model for 3D topological insulators. See Fig. 8 in Appendix A.) This result seems to be different from the value argued in the literature [9] where the $O(\text{meV})$ axion in the topological AFM insulators is discussed. Let us elaborate on this issue closely.

First of all, it is clear that the existence of dynamical axion does not depend on whether insulator is topological or not. This point is mentioned in Ref. [10]. Fig. 3 shows that the axion mass can be much suppressed near the critical point of the AFM phase in both the topological and normal insulators. In Ref. [9], on the other hand, $m_5 (= \phi_0) = 1 \text{ meV}$ is taken, which leads to meV scale axion mass. At a glance this looks possible; a small value of $U$ can give a suppressed $m_5$ since $m_5 \propto U^{1/5}$ in mean field approximation ($M_{\text{AFM}}$ in Ref. [9] corresponds to $m^2$ in Appendix B.3). However, it is no longer the AFM order if $U < U_{\text{crit}}$. Therefore, suppressed $U$ cannot be naively considered in this simple setting. This relates
to an intrinsic issue that Bi$_2$Se$_3$ does not have an AFM phase. A possible way out suggested in Ref. [9] is doping Fe to create the AFM order. In this way, the AFM order could be realized. However, doping Fe may not be successful due to the first-principles calculation [24]. A current candidate is Mn-doped topological insulator, Mn$_2$Bi$_2$Te$_5$ suggested in Ref. [23]. The first-principles calculation done by Ref. [25] shows that Mn$_2$Bi$_2$Te$_5$ has rich magnetic topological quantum states, including the AFM, FM and other magnetic states. The energy gap of the AFM phase indicates $m_5$ of the AFM phase is derived from the path integral. From the effective potential, the order parameter of the AFM is determined as the stationary point of the potential, which distinguishes the AFM or PM order. Axion potential is obtained from the effective potential. It is shown that the axion field value $\theta = 0$ or $\pi$ is the minimum of the axion potential in the PM order, meanwhile in the AFM order different values of $\theta$ are obtained as the minimum of the potential. The field value of the stationary point of axion is the static axion, and the dynamical axion is defined as a fluctuation around stationary value. The dynamical axion is predicted in four types of phases distinguished by the AFM/PM and the topological/normal states. The mass of axion turns out to be typically $\mathcal{O}(\text{eV})$. On the other hand, it can be much suppressed near the phase boundary between the AFM and PM orders. In either case, it is crucial to determine the value of the order parameter in a possible candidate, e.g., Mn$_2$Bi$_2$Te$_5$, to predict the axion mass.

Another possible direction to investigate the static/dynamical axion is to utilize the magnetoelectric effect. The magnetoelectric couplings in generic insulators are obtained by the first-principles calculation by Ref. [32]. For example, $\theta = 1.3 \times 10^{-3}$ and $1.07\pi$ are obtained for Cr$_2$O$_3$ and Bi$_2$Se$_3$. In addition, if Bi is magnetized, the value of $\theta$ is shifted to $\theta = \pi \pm 0.55$. On the experimental side, quantized Faraday and Kerr rotation due to Bi$_2$Se$_3$ film is observed precisely [33]. Recently, anisotropic topological magnetoelectric effect is observed in axion insulators [34]. Those are examples of “axion electrodynamics” as discussed in Refs. [9, 10]. Such methods using optical responses would make it possible to directly probe the order parameter of the magnetic

IV. CONCLUSIONS AND DISCUSSION

We have investigated axion in AFM insulators. In the analysis, the effective potential for the order parameter of the AFM phase is derived from the path integral. From the effective potential, the order parameter of the AFM is determined as the stationary point of the potential, which distinguishes the AFM or PM order. It is worth noticing that the dynamical axion should exist in the PM phase. On the other hand, there would be other degree of freedom in the PM phase. For example, $\phi$ is introduced in the circumstance where the AFM order is assumed (see, e.g., Eq. (B18)). If this assumption is relaxed, another scalar field should appear. Therefore, it would be nontrivial to find out dynamical axion mode under such contaminated circumstances. If the possible obstacles are overcome, however, the dynamical axion in the PM phase might be another tool for the future particle axion search.

4 Another interesting candidate is MnBi$_2$Te$_4$-family materials. Although they are not supposed to have dynamical axion, they are found to have controllable AFM and ferromagnetic orders. Therefore it is worth studying their properties for the future application. See, for example, Refs. [26–31].

5 Ref. [11] pointed out the existence of dynamical axion in topological PM insulators.
states and the properties of the static/dynamical axion. The formalism given here would be a help for finding and modeling realistic materials for the future particle axion or ALPs search. Searching a wide range of materials including ones that have no topological states or have ferromagnetic/paramagnetic phases might open a new possibility for particle axion search.

ACKNOWLEDGMENTS

We are grateful to Makoto Naka for valuable discussions in the early stage of this project and careful reading of the manuscript. We also thank Akihiko Sekine for useful discussions. This work was supported by JSPS KAKENHI Grant Numbers JP17K14278, JP17H02875, JP18H05542, and JP20H01894.

Appendix A: Effective model for 3D topological insulators

We give numerical results in the effective model for 3D topological insulators studied in Ref. [9]. The model is parametrized as,

\[(a^1, a^2, a^3, a^4, a^5) = (A_2 \sin k_x, A_2 \sin k_y, A_1 \sin k_z, M, m_5),\]

\[M = M - 2B_1 - 4B_2 + 2B_1 \cos k_z + 2B_2 (\cos k_x + \cos k_y),\]  

(A1)

where the gamma matrices are the same as Eq. (5). If we take \(A_1 = A_2 = A, B_1 = B_2 = -B,\) and \(M = m,\) and expand around \(k = 0,\) this model reduces to the Dirac model given in Eq. (6). Fig. 4 (5) shows \(\theta\) as function of \(\phi\) \((M\) or \(m)).\) As comparison, the results in the Dirac model are also plotted. It is seen that the results are qualitatively the same as the Dirac model.

Similar to Figs. 1, 2, and 3, \(V_\phi, V_\theta\), and the axion mass computed in the effective model for 3D topological insulators are plotted in Figs. 6, 7, and 8, respectively.
FIG. 5. θ as function of M (or m) for \( m_5 [\text{eV}] = \pm 0.01, \pm 0.1, \text{and} \pm 0.5 \) in the effective model for 3D topological insulators (left) and in the Dirac model (right). The other parameters are the same as Fig. 4.

Appendix B: Origin of \( d^5 \Gamma^5 \) term

In this section, we discuss a possible origin of \( \delta H \) term given in Eq. (13). For pedagogical purpose, we provide three types of derivations; derivations in the continuum space (Appendix B 1), in a discrete space (Appendix B 2) and by the mean field approximation (Appendix B 3).

1. In continuum space

To begin with, we consider one of sublattices since it is enough to get the basic idea of emerging a scalar degree of freedom that corresponds to \( m_5 (= \phi) \). The interaction term to cause the AFM order is given by following Hamiltonian:

\[
H_{\text{int}} = \frac{UV}{N} \int d^3 x n_\uparrow(x)n_\downarrow(x),
\]  

where arrow stands for the spin, \( V \) is the volume of the material, \( N \) is the number of site, and

\[
n_\sigma(x) = \psi_\sigma^\dagger \psi_\sigma \quad (\sigma = \uparrow, \downarrow).
\]

It is convenient to define the following quantities:

\[
n_{\pm}(x) \equiv n_\uparrow(x) \pm n_\downarrow(x),
\]

and take

\[
\langle n_+(x) \rangle = \text{const.},
\]

since the total number of electrons are unchanged. (This corresponds to Eq. (B46) in the mean field approximation.) Therefore, only \( n_- \) is a dynamical degree of freedom, and \( H_{\text{int}} \) becomes

\[
H_{\text{int}} = -\frac{UV}{4N} \int d^3 x n_+^2(x) + \text{const.}
\]

---

6 This term corresponds to the continuum limit of Eq. (B23) by making a replacement, \( \frac{1}{N} \sum_i \rightarrow \frac{1}{V} \int d^3 x \) and \( n_i\sigma \rightarrow \frac{1}{N} n_\sigma(x) \).

7 Strictly speaking, there is always a fluctuation around \( \langle n_+ \rangle \). However, it is not one we are interested in. See also the discussion when two sublattices are introduced.
For later discussion we define the Fourier expansion of $\psi_\sigma$ and $n_\sigma$ as

$$
\psi_\sigma(x) = \frac{1}{\sqrt{V}} \sum_k c_{k\sigma} e^{i k \cdot x},
$$

(B6)

$$
c_{k\sigma} = \frac{1}{\sqrt{V}} \int d^3x \psi_\sigma(x) e^{-i k \cdot x},
$$

(B7)

$$
n_\sigma(x) = \frac{1}{V} \sum_k \tilde{n}_\sigma(k) e^{i k \cdot x},
$$

(B8)

$$
\tilde{n}_\sigma(k) = \int d^3x n_\sigma(x) e^{-i k \cdot x} = \sum_q c_q^\dagger c_{q+k\sigma}.
$$

(B9)

Consequently, $\mathcal{H}_{\text{int}}$ in the momentum space is given by

$$
\mathcal{H}_{\text{int}} = \frac{U}{N} \sum_k \tilde{n}_\uparrow(k) \tilde{n}_\downarrow(-k) = -\frac{U}{4N} \sum_k \tilde{n}_-(k) \tilde{n}_-(-k) + \text{const.}
$$

(B10)

In terms of Euclidean time $\tau = it$, action of the interaction term is written by

$$
-S_{\text{int}}E = iS_{\text{int}} \equiv - \int d\tau \mathcal{H}_{\text{int}}.
$$

(B11)

Now we execute the Hubbard-Stratonovich transformation. It is also used in Ref. [35], which studies topological superconductors and superfluids. (See Ref. [36] for the renormalization group approach.) It is effectively the same as the inverse procedure of integrating out the heavy scalar particles to give the effective Lagrangian. (See Appendix E
FIG. 7. $V_{\theta}$ as function of $\theta/(2\pi)$ in the effective model for 3D topological insulators. Parameters are taken the same as Fig. 6.

for details.) Introducing $\tilde{\phi}(k)$ and using the following identity,

$$
- \left\{ \frac{N}{U} \tilde{\phi}(k) \tilde{\phi}(-k) + \frac{1}{2} \left[ \tilde{\phi}(k) \tilde{n}_-(-k) + \tilde{\phi}(-k) \tilde{n}_-(-k) \right] \right\}
$$

$$
= - \frac{N}{U} \left[ \tilde{\phi}(k) + \frac{U}{2N} \tilde{n}_-(-k) \right] \left[ \tilde{\phi}(-k) + \frac{U}{2N} \tilde{n}_-(-k) \right] + \frac{U}{4N} \tilde{n}_-(-k) \tilde{n}_-(-k),
$$

the Euclidean action gives

$$
\exp \left[ - \int d\tau \mathcal{H}_{\text{int}} \right] = \int \mathcal{D}\phi \exp \left\{ - \int d\tau \left\{ \sum_k \frac{N}{U} \tilde{\phi}(k) \tilde{n}_-(-k) + \frac{1}{2} \sum_k \left[ \tilde{\phi}(k) \tilde{n}_-(-k) + \tilde{\phi}(-k) \tilde{n}_-(-k) \right] \right\} \right\}
$$

$$
= \int \mathcal{D}\phi \exp \left\{ - \int d\tau \int d^3x \left[ \frac{N}{VU} \phi^2(x) + \phi(x) n_-(x) \right] \right\}. \tag{B13}
$$

Here we have omitted irrelevant constant term in the last step and we have used

$$
\tilde{\phi}(k) = \frac{1}{V} \int d^3x \phi(x)e^{-ik \cdot x}. \tag{B14}
$$

The second term on the rhs of Eq. (B13) is given in the momentum space as

$$
\int d^3x \phi(x) n_-(x) = \sum_{\alpha,\beta} c_{k\alpha}^\dagger c_{k\alpha} c_{k\beta}^\dagger c_{k\beta} \tilde{\phi}(q)
$$

$$
= \sum_k \left( c_{k\uparrow}^\dagger c_{k\uparrow}^\dagger c_{k\downarrow} c_{k\downarrow} \right) \tilde{\phi}(0) + \mathcal{O}(q)
$$

$$
= \sum_{k\alpha,\alpha'} c_{k\alpha}^\dagger (\tilde{\phi}(0) \sigma^z)_{\alpha\beta} c_{k\beta} + \mathcal{O}(q). \tag{B15}
$$
FIG. 8. Axion mass on \((U, M)\) plane calculated in the effective model for 3D topological insulators. \(A_1/a^2 = A_2/a^2 = 1\) eV and \(B_1/a^2 = B_2/a^2 = -0.5\) eV are taken. Solid (yellow) line shows the critical points; upper and lower regions separated by the solid line correspond to antiferromagnetic order (“AFM”) and paramagnetic order (“PM”), respectively. Dotted (green) line is boundary of topological insulator phase (“TI”) and normal insulator phase (“NI”).

Now we apply the above result to two sublattices, A and B. The interaction term to start with is

\[
\mathcal{H}_{\text{int}}^{A+B} = \frac{U V}{N} \int d^3 x \left( n_{A\uparrow}(x) n_{A\downarrow}(x) + n_{B\uparrow}(x) n_{B\downarrow}(x) \right),
\]

where \(N\) is the number of the sublattice A (B). As in the previous discussion, we define \(n_{i \pm}(x)\) (I=A, B),

\[
n_{i \pm}(x) \equiv n_{i \uparrow}(x) \pm n_{i \downarrow}(x).
\]

Since we are interested in the AFM order, \(n_{A -}\) and \(n_{B -}\) are not independent and related by

\[
n_{A -} + n_{B -} \approx \langle n_{A -} + n_{B -} \rangle = 0.
\]

Therefore, we obtain

\[
\exp \left[ - \int d\tau \mathcal{H}_{\text{int}}^{A+B} \right] = \int \mathcal{D}\phi \exp \left\{ - \int d\tau \left\{ \sum_k \frac{2 N}{U} \tilde{\phi}(k) \tilde{\phi}(-k) + \frac{1}{2} \sum_k [\tilde{\phi}(k)(\tilde{n}_{A -}(-k) - \tilde{n}_{B -}(-k)) + \tilde{\phi}(-k)(\tilde{n}_{A -}(k) - \tilde{n}_{B -}(k))] \right\} \right\}
\]

\[
= \int \mathcal{D}\phi \exp \left\{ - \int d\tau d^3 x \left[ \frac{2 N}{V U} \phi^2(x) + \phi(x)(n_{A -}(x) - n_{B -}(x)) \right] \right\}.
\]

and

\[
\int d^3 x \phi(x)(n_{A -}(x) - n_{B -}(x)) = \sum_k \tilde{\phi}(0) \left\{ c_{Ak}^\dagger \sigma^z c_{Ak} - c_{Bk}^\dagger \sigma^z c_{Bk} \right\} + \mathcal{O}(q).
\]

Here the summation over spin indices are implicit. This term corresponds to \(d^3 \Gamma^{5'} = \phi \Gamma^{5'}\) term in Eq. (2) after changing the basis from \((|P1_+^z, \sigma\rangle, |P2_-, \sigma\rangle)\) to \((|A, \sigma\rangle, |B, \sigma\rangle)\) where \(\sigma = \uparrow, \downarrow\). In this basis, \(\Gamma^{5'} = \text{diag}\{1, -1, -1, 1\}\)

---

8 As discussed below Eq. (B4), there are fluctuations around \(\langle n_{A+} \rangle\) and \(\langle n_{B+} \rangle\). In addition, if there is no the AFM order, i.e., the PM order, then \(\langle n_{A -} \rangle\) and \(\langle n_{B -} \rangle\) should be treated as independent degrees of freedom.
and Eq. (B19) becomes

\[
\int D\phi \exp \left\{ - \int d\tau \, d^3x \left[ M^2 \phi^2(x) - \phi(x)(n_{A-}(x) - n_{B-}(x)) \right] + \cdots \right\}
\]

\[
= \int D\tilde{\phi} \exp \left\{ - \int d\tau \sum_k \left[ VM^2 \tilde{\phi}(k)\tilde{\phi}(-k) - c_k^\dagger \Gamma^5 \tilde{\phi}(0)c_k + \cdots \right] \right\},
\]

(B21)

where \(c_k = (c_{Ak\uparrow}, c_{Ak\downarrow}, c_{Bk\uparrow}, c_{Bk\downarrow})\) and\(^9\)

\[
M^2 \equiv \frac{2}{(V/N)U} = \left( \int \frac{d^3q}{(2\pi)^3} \right) \frac{2}{U}.
\]

(B22)

2. In discrete space

As in the previous subsection, we first consider one of the sublattices and extend the result to the other later. In the discrete space, we use annihilation operator \(c_{i\sigma}\) where \(i\) is a label of site instead of the wavefunction \(\psi_\sigma(x)\). The interaction Hamiltonian is

\[
H_{\text{int}} = U \sum_i n_{i\uparrow} n_{i\downarrow},
\]

(B23)

where

\[
n_{i\sigma} = c_{i\sigma}^\dagger c_{i\sigma}.
\]

(B24)

While defining \(n_{i\pm}\) as

\[
n_{i\pm} \equiv n_{i\uparrow} \pm n_{i\downarrow},
\]

(B25)

only \(n_{i-}\) is dynamical since \(n_{i+} = \text{const.}\) as in Eq. (B4). Consequently, the interaction Hamiltonian is given by

\[
H_{\text{int}} = \frac{U}{4} \sum_i n_{i-}^2 + \text{const.}.
\]

(B26)

It is useful to give Fourier transformation of \(c_{i\sigma}\) and \(n_{i\sigma}\),

\[
c_{i\sigma} = \frac{1}{\sqrt{N}} \sum_k c_{k\sigma} e^{ik\cdot x},
\]

(B27)

\[
c_{k\sigma} = \frac{1}{\sqrt{N}} \sum_i c_{i\sigma} e^{-ik\cdot x},
\]

(B28)

\[
n_{i\sigma} = \frac{1}{N} \sum_k \tilde{n}_k c_{k\sigma},
\]

(B29)

\[
\tilde{n}_{k\sigma} = \sum_i n_{i\sigma} e^{-ik\cdot x} = \sum_q c_q^\dagger c_{q+k\sigma},
\]

(B30)

which leads to the Hamiltonian in the momentum space,

\[
H_{\text{int}} = \frac{U}{N} \sum_k \tilde{n}_{k\uparrow} \tilde{n}_{-k\downarrow} = - \frac{U}{4N} \sum_k \tilde{n}_{k-} - \frac{1}{4N} \sum_k \tilde{n}_{-k-} + \text{const.}
\]

(B31)

---

\(^9\) We use \((V/N)^{-1} = \int \frac{d^3q}{(2\pi)^3}\) where the integral is defined in the first Brillouin zone.
As in the continuum case, the Hubbard-Stratonovich transformation is done by using Eq. (B12). Then the Euclidean action of the interaction term is given by

$$\exp \left[ - \int d\tau \mathcal{H}_{\text{int}} \right]$$

$$= \int \mathcal{D}\tilde{\phi} \exp \left\{ - \int d\tau \left\{ \sum_k \frac{N}{U} \phi_k \tilde{\phi}_{-k} + \sum_k \frac{1}{2} \left[ \tilde{\phi}_k \tilde{n}_{-k} - \phi_{-k} \tilde{n}_{k} \right] \right\} \right\}$$

$$= \int \mathcal{D}\tilde{\phi} \exp \left\{ - \int d\tau \sum_i \left[ \frac{1}{U} \phi_i^2 + \phi_i n_i - \right] \right\} . \quad (B32)$$

Here we have defined the Fourier expansion of $\phi_i$ as

$$\phi_i = \sum_k \tilde{\phi}_k e^{i k \cdot x}, \quad (B33)$$

$$\tilde{\phi}_k = \frac{1}{N} \sum_i \phi_i e^{-i k \cdot x}, \quad (B34)$$

and the second term on the rhs of Eq. (B32) is written in the momentum space as

$$\sum_i \phi_i n_i = \sum_{q,k} \left( c_{k\uparrow}^\dagger c_{k+q\uparrow} - c_{k\downarrow} c_{k+q\downarrow} \right) \tilde{\phi}_{-q}$$

$$= \sum_k \left( c_{k\uparrow}^\dagger c_{k\uparrow} - c_{k\downarrow} c_{k\downarrow} \right) \tilde{\phi}_0 + \mathcal{O}(q)$$

$$= \sum_{k,\alpha,\beta} \left( \tilde{\phi}_0 \sigma^\alpha \right)_{\alpha\beta} c_k \tilde{\phi}_0 + \mathcal{O}(q). \quad (B35)$$

Extension to the other sublattice is trivial. As in the previous subsection, let us call the two sublattice as A and B. Then the interaction Hamiltonian is

$$\mathcal{H}_{\text{int}}^{A+B} = U \sum_i \left( n_{A\uparrow} n_{A\downarrow} + n_{B\uparrow} n_{B\downarrow} \right). \quad (B36)$$

Repeating the discussion so far, the Euclidean action is obtained as

$$\exp \left[ - \int d\tau \mathcal{H}_{\text{int}}^{A+B} \right]$$

$$= \int \mathcal{D}\tilde{\phi} \exp \left\{ - \int d\tau \left\{ \sum_k \frac{2N}{U} \tilde{\phi}_k \tilde{\phi}_{-k} + \frac{1}{2} \sum_k \left[ \tilde{\phi}_k (\tilde{n}_{A\uparrow} - \tilde{n}_{B\uparrow}) + \tilde{\phi}_{-k} (\tilde{n}_{A\downarrow} - \tilde{n}_{B\downarrow}) \right] \right\} \right\}$$

$$= \int \mathcal{D}\phi \exp \left\{ - \int d\tau \sum_i \left[ \frac{2}{U} \phi_i^2 + \phi_i (n_i - n_{i\uparrow}) \right] \right\} . \quad (B37)$$

The interaction part in momentum space is

$$\sum_i \phi_i (n_i - n_{i\uparrow}) = \sum_k \tilde{\phi}_0 \left\{ c_{A\uparrow}^\dagger \sigma^z c_{A\downarrow} - c_{B\uparrow}^\dagger \sigma^z c_{B\downarrow} \right\} + \mathcal{O}(q). \quad (B38)$$

Therefore we have obtained the same result as Eq. (B20) but $\tilde{\phi}_0(0)$ is replaced by $\tilde{\phi}_0$. Finally Eq. (B37) becomes

$$\int \mathcal{D}\phi \exp \left\{ - \int d\tau \sum_i \left[ \frac{2}{U} \phi_i^2 + c_{i\uparrow}^\dagger \Gamma_{i\uparrow} \phi_i \right] + \cdots \right\} = \int \mathcal{D}\phi \exp \left\{ - \int d\tau \sum_k \left[ \frac{2N}{U} \tilde{\phi}_k \tilde{\phi}_{-k} + c_k^\dagger \Gamma_{k\uparrow} \tilde{\phi}_0 c_k + \cdots \right] \right\}, \quad (B39)$$

where $c_i = (c_{A\uparrow}, c_{A\downarrow}, c_{B\uparrow}, c_{B\downarrow})$. When we make a continuum limit for space, i.e.,

$$\frac{1}{N} \sum_i \to \frac{1}{V} \int d^3x,$$

$$\phi_i \to \phi(x), \quad (B40)$$

$$\phi_i \to \phi(x), \quad (B41)$$
the mass term becomes
\[ \sum_i \frac{2}{U} \phi_i^2 \rightarrow \int d^3x \frac{2}{(V/N)U} \phi^2(x), \] (B42)
which agrees with Eq. (B21).

3. Mean field approximation

Another way to see the appearance of \( d^5 \Gamma^5 \) term is use the mean field approximation (MFA). We refer to Refs. [19, 21]. In the MFA,
\[ n_{i\uparrow} n_{i\downarrow} \approx n_{i\uparrow} \langle n_{i\downarrow} \rangle + \langle n_{i\uparrow} \rangle n_{i\downarrow} - \langle n_{i\uparrow} \rangle \langle n_{i\downarrow} \rangle - \langle c_{i\uparrow}^\dagger c_{i\downarrow} \rangle c_{i\downarrow}^\dagger c_{i\uparrow} - \langle c_{i\uparrow}^\dagger c_{i\downarrow} \rangle \langle c_{i\downarrow}^\dagger c_{i\uparrow} \rangle. \] (B43)
The expectation values are written by introducing \( m \)
\[ m^j = \frac{1}{2} \sum_{\alpha,\beta} \langle c_{i\alpha}^\dagger \sigma_{\alpha\beta}^j c_{i\beta} \rangle \quad (j = x, y), \] (B44)
\[ m^z = \frac{1}{2} \sum_{\alpha,\beta} \langle c_{i\alpha}^\dagger \sigma_{\alpha\beta}^z c_{i\beta} \rangle + \frac{1}{2} \langle c_{i\uparrow}^\dagger c_{i\downarrow} + c_{i\downarrow}^\dagger c_{i\uparrow} \rangle, \] (B45)
and we take
\[ \frac{1}{2} \langle c_{i\uparrow}^\dagger c_{i\uparrow} + c_{i\downarrow}^\dagger c_{i\downarrow} \rangle = 1, \] (B46)
since the half-filling model is considered. Then, it is straightforward to get
\[ n_{i\uparrow} n_{i\downarrow} \approx m^2 - \sum_{\alpha,\beta} \langle c_{i\alpha}^\dagger m \cdot \sigma_{\alpha\beta} c_{i\beta} \rangle. \] (B47)
Extending the argument to two sublattices is trivial. Now taking
\[ \langle S^j_A \rangle = m^j = \frac{1}{2} \sum_{\alpha,\beta} \langle c_{A\alpha}^\dagger \sigma_{\alpha\beta}^j c_{A\beta} \rangle \quad (j = x, y), \] (B48)
\[ \langle S^z_A \rangle = m^z = \frac{1}{2} \sum_{\alpha,\beta} \langle c_{A\alpha}^\dagger \sigma_{\alpha\beta}^z c_{A\beta} \rangle + \frac{1}{2} \langle c_{A\uparrow}^\dagger c_{A\downarrow} + c_{A\downarrow}^\dagger c_{A\uparrow} \rangle, \] (B49)
and
\[ \langle S_A \rangle + \langle S_B \rangle = 0, \] (B50)
since we are interested in the AFM order, we get
\[ U \sum_i (n_{A\uparrow} n_{A\downarrow} + n_{B\uparrow} n_{B\downarrow}) \approx 2U \sum_i m^2 - U \sum_i c_{A\uparrow}^\dagger m \cdot \sigma c_{A\downarrow} + U \sum_i c_{B\uparrow}^\dagger m \cdot \sigma c_{B\downarrow}. \] (B51)
In the current model, we consider that only \( m^z \) is nonzero. Changing the variable to \( \phi \) by \( \phi = -Um^z \), we finally obtain
\[ U \sum_i (n_{A\uparrow} n_{A\downarrow} + n_{B\uparrow} n_{B\downarrow}) \approx 2 \int \frac{d^3x}{U} \phi^2 + \sum_i c_{i\uparrow}^\dagger \phi \Gamma^5 c_i. \] (B52)
It is seen that both mass term for \( \phi \) and \( m^5 \Gamma^5 \) term appear.
**Appendix C: Derivation of effective Lagrangian for φ**

We show how to derive the effective potential (24) and stiffness $J$ (33) from $\text{Tr}(G_0 \delta H)^n$ term in Eq. (21). It corresponds to calculation of one-loop diagram with external scalar fields those three-momenta are zero. It is similar to the Coleman-Weinberg potential [37], but the the result turns out to be non-logarithmic function. In the following calculation, the continuum limit in the coordinate and momentum space is taken. We define the Fourier expansion of $G_0$ and $φ$ as

$$G_0(x - y) = \int \frac{d^4k}{(2\pi)^4} \tilde{G}_0(k) e^{-ik \cdot (x - y)} , \quad \text{(C1)}$$

$$\phi(x) = \int \frac{d^4k}{(2\pi)^4} \tilde{\phi}(k) e^{-ik \cdot x} , \quad \text{(C2)}$$

where $k \cdot x = k^0 x^0 - k \cdot x$.

First we show how to derive the effective potential. Note that the trace vanishes when $n$ is odd. Thus, let us begin with $n = 2$:

$$\text{Tr}(G_0 \delta H)^2 = \int \prod_{i=1}^3 d^4x_i \text{tr} [G_0(x_1 - x_2) \phi(x_2) G_0(x_2 - x_3) \phi(x_3)] \delta^{(4)}(x_3 - x_1)$$

$$= \int \frac{d^4k}{(2\pi)^4} \frac{d^4q}{(2\pi)^4} \text{tr} \left[ \tilde{G}_0(q) \Gamma^5 \tilde{G}_0(q + k) \Gamma^5 \right] \tilde{\phi}(-k) \tilde{\phi}(k) . \quad \text{(C3)}$$

Here trace part gives

$$\text{tr} \left[ \tilde{G}_0(q) \Gamma^5 \tilde{G}_0(q + k) \Gamma^5 \right] = 4 \left\{ \frac{q^0 - \epsilon_0(q)}{((q^0 - \epsilon_0(q))^2 - |d_0(q)|^2)} \right\} \frac{q^0 + k^0 - \epsilon_0(q + k)}{((q^0 + k^0 - \epsilon_0(q + k))^2 - |d_0(q + k)|^2)} , \quad \text{(C4)}$$

where index $a$ is contracted. To give the effective potential we can take $k = 0$. As a result, it is given in a simple form,

$$\text{tr} \left[ \tilde{G}_0(q) \Gamma^5 \tilde{G}_0(q + k) \Gamma^5 \right] \Big|_{k=0} = 4 \left( \frac{q^0 - \epsilon_0(q)}{((q^0 - \epsilon_0(q))^2 - |d_0(q)|^2)} \right) \frac{1}{|d_0(q)|^2} . \quad \text{(C5)}$$

In the similar manner, higher polynomials are calculated as

$$\text{Tr}(G_0 \delta H)^n = \int \prod_{i=1}^{n+1} d^4x_i \text{tr} [G_0(x_1 - x_2) \phi(x_2) G_0(x_2 - x_3) \phi(x_3) \cdots G_0(x_n - x_{n+1}) \phi(x_{n+1})] \delta^{(4)}(x_{n+1} - x_1)$$

$$= \int \prod_{i=1}^{n-1} \frac{d^4k_i}{(2\pi)^4} \frac{d^4q}{(2\pi)^4} \text{tr} \left[ \tilde{G}_0(q) \Gamma^5 \tilde{G}_0(q + k_1) \Gamma^5 \tilde{G}_0(q + k_1 + k_2) \Gamma^5 \cdots \tilde{G}_0(q + \sum_i^{n-1} k_i) \Gamma^5 \right]$$

$$\times \tilde{\phi}(-k_1) \tilde{\phi}(-k_2) \tilde{\phi}(-k_3) \cdots \tilde{\phi}(-k_{n-1}) \tilde{\phi}(\sum_i^{n-1} k_i) , \quad \text{(C6)}$$

where $n \geq 2$. To get the $\phi^n$ terms, we can take $k_i = 0$. Then the trace part is

$$\text{tr}[\cdots]|_{k_i=0} = \text{tr}[\tilde{G}_0(q) \Gamma^n \tilde{G}_0(q)]$$

$$= 4 \left( \frac{q^0 - \epsilon_0(q)}{((q^0 - \epsilon_0(q))^2 - |d_0(q)|^2)} \right)^m \frac{1}{|d_0(q)|^2} , \quad \text{(C7)}$$

where $n = 2m$ ($m = 1, 2, 3, \cdots$). Using this formula, the last term in Eq. (21) gives

$$-\text{Tr} \left[ \sum_{n=1}^{\infty} \frac{1}{n!} (G_0 \delta H)^n \right] \geq -4i \int d^4x \int \frac{d^4q}{(2\pi)^4} \frac{d^4q}{(2\pi)^4} \sum_{m=1}^{\infty} \frac{1}{2m} \left( \frac{(-1)^m \phi^{2m}}{(q^0)^2 + |d_0|^2} \right)$$

$$= 2i \int d^4x \int \frac{d^4q}{(2\pi)^4} \log \left[ 1 + \frac{\phi^2}{(q^0)^2 + |d_0|^2} \right] , \quad \text{(C8)}$$
Here we assume that $q^0$ integral is from $-\infty$ to $+\infty$, and we use the Wick rotation of the the integral path as
\[
\int_{-\infty}^{\infty} dq^0 = i \int_{-\infty}^{\infty} dq_E^0 ,
\] (C9)
Finally the effective potential for $\phi (= m_5)$ is obtained as
\[
V_\phi = -2 \int \frac{d^3q}{(2\pi)^3} \frac{dq_E^0}{2\pi} \log \left[ 1 + \frac{\phi^2}{(q_E^0)^2 + |d_0|^2} \right] + M^2\phi^2
\]
\[
\quad = -2 \int \frac{d^3q}{(2\pi)^3} (\sqrt{|d_0|^2 + \phi^2} - |d_0|) + M^2\phi^2 .
\] (C10)

The stiffness $J$ is obtained as an coefficient of the time-derivative term of the dynamical field. It is determined after the potential minimum is found. Therefore, instead of using Eqs. (12) and (13), we take
\[
H'_0(k) = \epsilon_0(k)1_{4 \times 4} + \sum_{a=1}^{5} d^a(k)\Gamma^a ,
\] (C11)
\[
\delta H'(k) = \delta\phi\Gamma^5 ,
\] (C12)
where now $d^5 = \phi_0$ (and the others are the same) and $\delta\phi = \phi - \phi_0$. The propagator is given similarly to Eq. (23) as
\[
\tilde{G}(k) = \frac{k^0 - \epsilon_0(k) + d^a(k)\Gamma^a}{(k^0 - \epsilon_0(k))^2 - |d(k)|^2} ,
\] (C13)
where $|d|^2 \equiv \sum_{a=1}^{5} d^a d^a + \phi_0^2$. To derive the time-derivative kinetic term, the quadratic term of $\delta H'$ should be expanded in terms of $k^0$ (but $k = 0$ can be taken). The trace part is given by
\[
\left. \text{tr} \left[ \tilde{G}(q)\Gamma^5 \tilde{G}(q + k)\Gamma^5 \right] \right|_{k=0} = 4 \frac{(q^0 - \epsilon_0(q))^2 + (q^0 - \epsilon_0(q))k^0 - |d_0(q)|^2 + \phi_0^2}{((q^0 - \epsilon_0(q))^2 - |d(q)|^2)((q^0 + k^0 - \epsilon_0(q))^2 - |d(q)|^2)} .
\] (C14)
After expanding with respect to $k^0$, we get the kinetic term
\[
-\text{Tr} \left[ \frac{1}{i^n} (G\delta H')^n \right] \left|_{n=2} \supset i \int \frac{d^4k}{(2\pi)^4} \delta\tilde{\phi}(-k)\delta\phi(k) \int \frac{d^3q}{(2\pi)^3} \frac{|d_0|^2}{4(|d_0|^2 + \phi_0^2)^{5/2}} (k^0)^2
\]
\[
\quad = J \int d^4x \delta\phi(-\partial_0^2)\delta\phi .
\] (C15)
where $\delta\tilde{\phi}$ is Fourier transformation of $\delta\phi$ and
\[
J = \int \frac{d^3q}{(2\pi)^3} \frac{|d_0|^2}{4(|d_0|^2 + \phi_0^2)^{5/2}} .
\] (C16)

**Appendix D: $\theta$ term as chiral anomaly**

In a special case of the Dirac model, $\theta$ can be derived as the path integral measure due to the chiral rotation of the electron field $\psi$ [19, 21]. In this section we apply the technique to the present model and clarify an issue claimed in Ref. [21] that $\theta$ derived in this technique can not be applied in some circumstances.

When $B = 0$ and $\epsilon_0 = 0$, the Hamiltonian is given by
\[
H(k) = Ak_x\Gamma^1 + Ak_y\Gamma^2 + Ak_z\Gamma^3 + m\Gamma^4 + \phi\Gamma^5 .
\] (D1)

In the $(|A, \sigma\rangle, |B, \sigma\rangle)$ ($\sigma = \uparrow, \downarrow$) basis, the Gamma matrix is given as
\[
\Gamma^{\alpha\beta} \equiv U^{\alpha\beta}U^\dagger ,
\] (D2)
\[
U = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix} .
\] (D3)
To be concrete,
\[ \Gamma^{1\nu} = \begin{pmatrix} \sigma^x & 0 \\ 0 & -\sigma^x \end{pmatrix}, \quad \Gamma^{2\nu} = \begin{pmatrix} \sigma^y & 0 \\ 0 & -\sigma^y \end{pmatrix}, \quad \Gamma^{3\nu} = \begin{pmatrix} 0 & -i \mathbf{1} \\ i \mathbf{1} & 0 \end{pmatrix}, \quad \Gamma^{4\nu} = \begin{pmatrix} 0 & -\mathbf{1} \\ -\mathbf{1} & 0 \end{pmatrix}, \quad \Gamma^{5\nu} = \begin{pmatrix} \sigma^z & 0 \\ 0 & -\sigma^z \end{pmatrix}. \] (D4)

\( \Gamma^\alpha \) corresponds to \( \bar{\alpha}_\mu \) rotated by \( U_3 \) in Ref. [19], except for an extra sign in \( \bar{\alpha}_5 \). Or if one makes another transformation,
\[ \tilde{U} = U \Gamma^\alpha \bar{U}^\dagger, \]
\[ U = \frac{1}{\sqrt{2}} \text{diag}(1 + i, 1 - i, 1 - i, 1 + i), \] (D5) (D6)
the Dirac \( \alpha \) matrices in the Dirac representation are obtained,
\[ \tilde{\Gamma}^1 = \begin{pmatrix} 0 & \sigma^x \\ \sigma^x & 0 \end{pmatrix}, \quad \tilde{\Gamma}^2 = \begin{pmatrix} 0 & \sigma^y \\ \sigma^y & 0 \end{pmatrix}, \quad \tilde{\Gamma}^3 = \begin{pmatrix} 0 & \sigma^z \\ \sigma^z & 0 \end{pmatrix}, \quad \tilde{\Gamma}^4 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad \tilde{\Gamma}^5 = \begin{pmatrix} 0 & \mathbf{1} \\ -\mathbf{1} & 0 \end{pmatrix}. \] (D7)

Here the Dirac \( \alpha \) matrices corresponds to \( (\alpha, \beta) = (\tilde{\Gamma}^1, \tilde{\Gamma}^2, \tilde{\Gamma}^3, \tilde{\Gamma}^4) \). Therefore,
\[ \tilde{U} H(k) \tilde{U}^\dagger = \alpha \cdot k' + \beta m + \phi \tilde{\Gamma}^5 \]
\[ = \beta(\gamma \cdot k' + m + \phi \gamma_5), \] (D8)
where we have changed variable \( k \) as \( A k = k' \), and introduced the Dirac gamma matrix \( \gamma^\mu = (\beta, \beta \alpha) \) and \( \gamma_5 = i \gamma^0 \gamma^1 \gamma^2 \gamma^3 \). Consequently, this Hamiltonian leads to the following action,
\[ S = \int d^4 x \bar{\psi} \gamma^\mu (\partial_\mu - i e A_\mu) - m - i \phi \gamma_5 |\psi|, \] (D9)
where \( \bar{\psi} = \psi^\dagger \gamma^0 \) and we have added vector potential \( A_\mu \) of \( U(1)_{\text{em}} \). Then chiral rotation of \( \psi \) gives the chiral anomaly term in the QED [38, 39],
\[ \Delta S = -\frac{\alpha}{4\pi} \int d^4 x \Theta F_\mu^{\nu} \tilde{F}^{\mu\nu} = \frac{\alpha}{\pi} \int d^4 x \Theta \mathbf{E} \cdot \mathbf{B}, \] (D10)
where \( \tilde{F}^{\mu\nu} = \frac{1}{2} \epsilon^{\mu\nu\rho\sigma} F_{\rho\sigma} \) \((\epsilon^{0123} = +1)\) and
\[ \Theta = \frac{\pi}{2} [1 - \text{sgn}(m)] \text{sgn}(\phi) + \tan^{-1} \frac{\phi}{m}. \] (D11)

Here we have set the domain of \( \tan^{-1} \) as \([-\pi, \pi]\). This is consistent with Ref. [21], except that the sign of \( m \) and we have used single degree of freedom for electron field \( \psi \). In the model considered in Refs. [19, 21], there are three Dirac points and they expand the Hamiltonian at each Dirac points. That is why they have three degree of freedom for electron field. The sign of \( M_f e^{i\pi/2} \) in Eq. (30) of Ref. [21] is supposed to be a plus. Comparing to the result in Ref. [19] (v1 on arXiv), their result is a factor of two smaller. In addition, it is claimed that first term is \( 1/2 \), instead of \( \pi/2 \), in the topological phase.\(^{10}\) The authors of Ref. [21] claim that the expression of \( \Theta \) cannot be applied when \( Um_f/\delta t' \gg 1 \). \((Um_f/\delta t' \) corresponds to \( \phi/m \) in our notation.) This is misleading because the derivation by chiral rotation in the path integral is exact and there is no approximation. However, it should be noted that in this calculation the cutoff of the momentum integral is taken to be infinity. To put it more correctly, therefore, this result is reliable when \( Um_f/\delta t' \) is smaller than the cutoff momentum. Although the Dirac model is the low energy effective model, if the cutoff momentum is taken to be infinity, then we get from Eq. (28)
\[ \theta = \text{sgn}(\phi) \left[ \frac{\pi}{2} - \tan^{-1} \frac{m}{|\phi|} \right], \] (D12)
which is the same result with Eq. (D11).

\(^{10}\) Those are just typos. We thank S. Chigusa for confirming it.
Appendix E: Another derivation of the Lagrangian for $\phi$

In the Dirac model with $B = 0$ discussed in Appendix D, we can derive the Lagrangian for $\phi$ in a way that is familiar to particle physicists. We start with the following effective Lagrangian,

$$\mathcal{L}_{\text{eff}} = \bar{\psi} [i\gamma^\mu (\partial_\mu - ieA_\mu) - m] \psi - \frac{1}{2M^2_\phi} (\bar{\psi} \gamma_5 \psi)^2.$$  \hspace{1cm} (E1)

The Hubbard-Stratonovich transformation is the inverse procedure of integrating out heavy scalar particles. In fact, above effective Lagrangian is given by integrating out a scalar field $\phi$ that has a Yukawa interaction with $\psi$,

$$\mathcal{L} = \bar{\psi} [i\gamma^\mu (\partial_\mu - ieA_\mu) - m - i\phi \gamma_5] \psi - M^2_\phi \phi^2.$$  \hspace{1cm} (E2)

The last so-called four-Fermi interaction term in Eq. (E1) corresponds to Eq. (7). Taking into account the background of the AFM order $n_A = -n_B$, $M^2_\phi$ is related to $U$ as

$$\frac{1}{2M^2_\phi} = -\frac{UV}{4N},$$  \hspace{1cm} (E3)

to obtain

$$M^2_\phi = \frac{2}{(V/N)U}.$$  \hspace{1cm} (E4)

This is the same result with Eq. (B22). Therefore, we can use the Lagrangian (E2) as starting point, and compute the effective Lagrangian for $\phi$. As a result, we get

$$V^{(\text{Dirac})}_\phi = -2 \int \frac{d^3q}{(2\pi)^3} \left( \sqrt{E^2_q + \phi^2} - E_q \right) + M^2_\phi \phi^2,$$  \hspace{1cm} (E5)

where $E_q = \sqrt{q^2 + m^2}$. This agrees with Eq. (24) but taking $A = 1$ and $B = 0$. As mentioned a couple of times, the momentum integral should have a cutoff since the Dirac model is low energy effective model.
