- **Premise of the study:** *Rehmannia glutinosa* (Scrophulariaceae) is used in traditional Chinese medicine. Microsatellite primers were developed and characterized for this species to evaluate its genetic diversity and population genetic structure.
- **Methods and Results:** Sixteen microsatellite loci were isolated from *R. glutinosa* using an enriched genomic library, and these markers were characterized in two wild populations of this species. The number of alleles per locus ranged from two to 20. A high genetic diversity was observed in two populations, with average observed heterozygosity of 0.812 and 0.794, and average expected heterozygosity of 0.802 and 0.814, respectively.
- **Conclusions:** *Rehmannia glutinosa* is an important medicinal resource. The genetic markers described in our study will be useful for future population genetic studies and molecular breeding programs on this species.

**Key words:** genetic diversity; microsatellite; *Rehmannia glutinosa*; Scrophulariaceae.

*Rehmannia glutinosa* (Gaertn.) Libosch. ex Fisch. & C. A. Mey. (Scrophulariaceae) is a perennial herbaceous species of medicinal value (Zhou, 2002; Shao et al., 2008). Its tuberous roots are commonly used in Chinese traditional medicine (Wen et al., 2002). In recent decades, a significant number of chemical and pharmacological studies have been performed on *R. glutinosa* (Zhang et al., 2008; Chang et al., 2011). More than 70 compounds, including iridoids, saccharides, amino acids, inorganic ions, and other trace elements, have been found in the herb (Zhang et al., 2008). Many studies show that some active ingredients in the roots of *R. glutinosa* possess broad pharmacological actions for protecting gastric mucosa and restraining pulmonary fibrosis (Liu et al., 2009). In addition, the root has been demonstrated to improve hematopoiesis, have anti-inflammatory and antitumor activities, decrease blood sugar, and promote the proliferation of vascular endothelial cells (Liu et al., 2009).

Genetic knowledge about *R. glutinosa*, such as its genetic diversity, genetic structure, and gene flow, serves as a foundation for cultivating improved varieties and exploiting and utilizing Chinese traditional medicine resources (Zhang et al., 2012). Simple sequence repeats (SSRs) are highly polymorphic, multiallelic, reproducible, abundantly distributed in the genome, and easy to interpret (Tanya et al., 2011). They are also codominant inheritance markers and can provide the amplified result of the heterozygote or the homozygote. In this study, we isolated 16 microsatellite loci from *R. glutinosa* and used these loci as markers to estimate the genetic diversity of two wild populations.

**METHODS AND RESULTS**

Forty-four individual leaves were collected from two wild populations of *R. glutinosa*: Hebi (HB: 35°36′00″N, 114°12′00″E) and Jiaozuo (JZ: 35°13′48″N, 113°25′48″E). The voucher specimens (*Rehmannia glutinosa* HB090001 and *Rehmannia glutinosa* JZ090001 for the HB and JZ populations, respectively) are deposited in the herbarium of Henan Agricultural University (HEAC). These leaf samples were dried quickly with silica gel and stored at −20°C. The total DNA was isolated from the dried leaves using a modified cetyltrimethylammonium bromide (CTAB) method (Fang et al., 2009) and purified with a Universal DNA Purification Kit (Tiangen Biotech, Beijing, China). The purified DNA was digested with the enzyme *Rsa*I, and the digested DNA fragments were linked to SuperSNX-24F (5′-GGATAAGCCTAGCTAGCAGAATC-3′) and SuperSNX-24R (5′-GATTCTGTCTACGAGCTCTTAAACAAA-3′) adapters. Using biotinylated (AC)6, (AG)6, and (ATG)12 probes (New England Biolabs, Beverly, Massachusetts, USA) and SuperSNX-24F and SuperSNX-24R adapters, the ligated fragments were hybridized and captured by streptavidin-coated magnetic beads. After purification, DNA fragments were ligated to the PMD18-T vectors (TaKaRa Biotechnology Co., Dalian, China) and transformed into DH5α cells (TaKaRa Biotechnology Co.). All white clones were tested with PCR amplification using M13F and M13R primers. Ninety-six positive clones with inserted fragments ranging from 400 to 1000 bp were selected and sequenced on an ABI 3730 DNA analyzer (Applied Biosystems, Foster City, California, USA). Out of the 96 clones, 48 contained microsatellite repeats. Based on the sequences with microsatellite repeats in the middle region of the sequences, 32 primer pairs were designed using the primer Premier 5.0 (PREMIER Biosoft International, Palo Alto, California, USA). Using 12 *R. glutinosa* individuals, PCR amplifications were performed in 10 μL of a solution containing approximately 50 ng of genomic DNA, 10 μM...
Sixteen microsatellite loci were isolated from *Rehmannia glutinosa*, and these loci were analyzed to estimate the genetic diversity of two wild populations. Our study observed a high genetic diversity in the two wild populations. The genetic markers described in our study will be useful for future population genetics studies and molecular breeding programs on this species.

CONCLUSIONS

Sixteen microsatellite loci were isolated from *R. glutinosa*, and these loci were analyzed to estimate the genetic diversity of two wild populations. Our study observed a high genetic diversity in the two wild populations. The genetic markers described in our study will be useful for future population genetics studies and molecular breeding programs on this species.
