Note:

- The number of events quoted for DAΦNE are based on a luminosity of $5 \cdot 10^{32} \ cm^{-2}\ s^{-1}$, which is equivalent \[1\] to an annual rate of $9 \cdot 10^9 \ (1.1 \cdot 10^9)$ tagged $K^\pm \ (K_L)$ (1 year $= 10^7 \ s$ assumed).

- Whenever we quote a branching ratio for a semileptonic $K^0$ decay, it stands for the branching ratio of the corresponding $K_L$ decay, e.g.,

$$BR(K^0 \to \pi^- l^+ \nu) \equiv BR(K_L \to \pi^\pm l^\mp \nu).$$

- We use the data from the Particle Data Group edition 1990 \[3\] throughout. Please contact one of the authors in case that very high precision is needed for a particular matrix element. We would then convert the relevant quantity to the newest data compilation available.

- If not stated explicitly, we always use for the low-energy constants $L_1, \ldots, L_{10}$ the values displayed in table 1 in ref. \[2\].

- More notation is provided in appendix \[A\].
1 Radiative $K_{l2}$ decays

We consider the $K_{l2\gamma}$ decay

$$K^+(p) \rightarrow l^+(p_l)\nu_l(p_\nu)\gamma(q) \quad [K_{l2\gamma}] \quad (1.1)$$

where $l$ stands for $e$ or $\mu$, and $\gamma$ is a real photon with $q^2 = 0$. Processes where the (virtual) photon converts into a $e^+e^-$ or $\mu^+\mu^-$ pair are considered in the next subsection. The $K^-$ mode is obtained from (1.1) by charge conjugation.

1.1 Matrix elements and kinematics

The matrix element for $K^+ \rightarrow l^+\nu_l\gamma$ has the structure

$$T = -iG_F e V_{us} \epsilon^*_\mu \{ F_K L^\mu - H^\mu\nu l_\nu \} \quad (1.2)$$

with

$$L^\mu = m_l \bar{u}(p_\nu) (1 + \gamma_5) \left( \frac{2p^\mu}{2pq} - \frac{2p_l^\mu + \not{q}\gamma^\mu}{2pq} \right) v(p_l)$$

$$l^\nu = \bar{u}(p_\nu) \gamma^\nu (1 - \gamma_5) v(p_l)$$

$$H^\mu\nu = iV(W^2)\epsilon^{\mu\nu\alpha\beta} q_\alpha p_\beta - A(W^2)(qWg^{\mu\nu} - W^\mu q^\nu)$$

$$W^\mu = (p - q)^\mu = (p_l + p_\nu)^\mu. \quad (1.3)$$

Here, $\epsilon_\mu$ denotes the polarization vector of the photon with $q^2 \epsilon_\mu = 0$, whereas $A, V$ stand for two Lorentz invariant amplitudes which occur in the general decomposition of the tensors

$$I^{\mu\nu} = \int dx e^{ix^2+iWy} < 0 | TV^\nu_{em}(x) I^{\nu}_{4-i5}(y) | K^+(p) > \ , \ I = V, A. \quad (1.4)$$

The form factor $A(V)$ is related to the matrix element of the axial (vector) current in (1.4). In appendix C we display the general decomposition of $A^{\mu\nu}, V^{\mu\nu}$ for $q^2 \neq 0$ and provide also the link with the notation used by the PDG [3] and in [4, 5].

The term proportional to $L^\mu$ in (1.2) does not contain unknown quantities – it is determined by the amplitude of the nonradiative decay $K^+ \rightarrow l^+\nu_l$. This part of the amplitude is usually referred to as “inner Bremsstrahlung (IB) contribution”, whereas the term proportional to $H^{\mu\nu}$ is called “structure dependent (SD) part”.

The form factors are analytic functions in the complex $W^2$-plane cut along the positive real axis. The cut starts at $W^2 = (M_K+2M_\pi)^2$ for $A$ (at $W^2 = (M_K+M_\pi)^2$ for $V$). In our phase convention, $A$ and $V$ are real in the physical region of $K_{l2\gamma}$ decays,

$$m_l^2 \leq W^2 \leq M_K^2. \quad (1.5)$$
The kinematics of (spin averaged) $K_{l2\gamma}$ decays needs two variables, for which we choose the conventional quantities

$$x = 2pq/M_K^2, \quad y = 2pp_l/M_K^2.$$  \hspace{1cm} (1.6)

In the $K$ rest frame, the variable $x$ ($y$) is proportional to the photon (charged lepton) energy,

$$x = 2E_\gamma/M_K, \quad y = 2E_l/M_K,$$  \hspace{1cm} (1.7)

and the angle $\theta_{l\gamma}$ between the photon and the charged lepton is related to $x$ and $y$ by

$$x = \frac{(1 - y/2 + A/2)(1 - y/2 - A/2)}{1 - y/2 + A/2\cos\theta_{l\gamma}}, \quad A = \sqrt{y^2 - 4r_l}.$$  \hspace{1cm} (1.8)

In terms of these quantities, one has

$$W^2 = M_K^2(1 - x) ; \quad (q^2 = 0).$$  \hspace{1cm} (1.9)

We write the physical region for $x$ and $y$ as

$$2\sqrt{r_l} \leq y \leq 1 + r_l$$

$$1 - \frac{1}{2}(y + A) \leq x \leq 1 - \frac{1}{2}(y - A)$$ \hspace{1cm} (1.10)

or, equivalently, as

$$0 \leq x \leq 1 - r_l$$

$$1 - x + \frac{r_l}{1 - x} \leq y \leq 1 + r_l$$ \hspace{1cm} (1.11)

where

$$r_l = m_l^2/M_K^2 = \left\{ \begin{array}{l}
1.1 \cdot 10^{-6}(l = e) \\
4.6 \cdot 10^{-2}(l = \mu)
\end{array} \right.$$ \hspace{1cm} (1.12)

### 1.2 Decay rates

The partial decay rate is

$$d\Gamma = \frac{1}{2M_K(2\pi)^5} \sum_{spins} |T|^2 dLIPS(p; p_l, p_\nu, q).$$ \hspace{1cm} (1.13)

The Dalitz plot density

$$\rho(x, y) = \frac{d^2\Gamma}{dx dy} = \frac{M_K}{256\pi^3} \sum_{spins} |T|^2.$$ \hspace{1cm} (1.14)
is a Lorentz invariant function which contains $V$ and $A$ in the following form:

$$\rho(x, y) = \rho_{IB}(x, y) + \rho_{SD}(x, y) + \rho_{INT}(x, y)$$

$$\rho_{IB}(x, y) = A_{IB} f_{IB}(x, y)$$

$$\rho_{SD}(x, y) = A_{SD} M_K^2 \left[ (V + A)^2 f_{SD^+}(x, y) + (V - A)^2 f_{SD^-}(x, y) \right]$$

$$\rho_{INT}(x, y) = A_{INT} M_K \left[ (V + A) f_{INT^+}(x, y) + (V - A) f_{INT^-}(x, y) \right]$$ (1.15)

where

$$f_{IB}(x, y) = \left[ \frac{1 - y + r_l}{x^2(x + y - 1 - r_l)} \right] \left[ x^2 + 2(1 - x)(1 - r_l) - \frac{2xr_l(1 - r_l)}{x + y - 1 - r_l} \right]$$

$$f_{SD^+}(x, y) = [x + y - 1 - r_l] \left[ (x + y - 1)(1 - x) - r_l \right]$$

$$f_{SD^-}(x, y) = [1 - y + r_l] \left[ (1 - x)(1 - y) + r_l \right]$$

$$f_{INT^+}(x, y) = \left[ \frac{1 - y + r_l}{x(x + y - 1 - r_l)} \right] \left[ (1 - x)(1 - x - y) + r_l \right]$$

$$f_{INT^-}(x, y) = \left[ \frac{1 - y + r_l}{x(x + y - 1 - r_l)} \right] \left[ x^2 - (1 - x)(1 - x - y) - r_l \right]$$ (1.16)

and

$$A_{IB} = 4r_l \left( \frac{F_K}{M_K} \right)^2 A_{SD}$$

$$A_{SD} = \frac{G_F^2 |V_{us}|^2 \alpha}{32\pi^2} M_K^5$$

$$A_{INT} = 4r_l \left( \frac{F_K}{M_K} \right) A_{SD} .$$ (1.17)

For later convenience, we note that

$$A_{SD} = \frac{\alpha}{8\pi r_l(1 - r_l)^2} \left( \frac{M_K}{F_K} \right)^2 \Gamma(K \to l\nu_l) .$$ (1.18)

The indices IB, SD and INT stand respectively for the contribution from inner Bremsstrahlung, from the structure dependent part and from the interference term between the IB and the SD part in the amplitude.

To get a feeling for the magnitude of the various contributions IB, SD$^\pm$ and INT$^\pm$ to the decay rate, we consider the integrated rates

$$\Gamma_I = \int_{R_I} dxdyd\rho_I(x, y) ; \quad I = SD^\pm, INT^\pm, IB ,$$ (1.19)

where $\rho_{SD} = \rho_{SD^+} + \rho_{SD^-}$ etc. For the region $R_I$ we take the full phase space for $I \neq IB$, and

$$R_{IB} = 214.5 \text{MeV}/c \leq p_l \leq 231.5 \text{MeV}/c .$$ (1.20)
Table 1.1: The quantities $X_I, N_I$. SD$^\pm$ and INT$^\pm$ are evaluated with full phase space, IB with restricted kinematics \( (1.20) \).

|   | SD$^+$ | SD$^-$ | INT$^+$ | INT$^-$ | IB  |
|---|--------|--------|---------|---------|-----|
| $X_I$ | $1.67 \cdot 10^{-2}$ | $1.67 \cdot 10^{-2}$ | $-8.22 \cdot 10^{-8}$ | $3.67 \cdot 10^{-6}$ | $3.58 \cdot 10^{-6}$ | $K_{e2\gamma}$ |
| $N_I$ | $2$ | $2$ | $1$ | $1$ | $0$ | $K_{\mu2\gamma}$ |

for the Bremsstrahlung contribution. Here \( p_l \) stands for the modulus of the lepton three momentum in the kaon rest system \( [1] \). We consider constant form factors $V, A$ and write for the rates and for the corresponding branching ratios

$$ \Gamma_I = A_{SD} \{ M_K(V \pm A) \}^{N_I} X_I $$

$$ BR_I = \Gamma_I / \Gamma_{tot} = N \{ M_K(V \pm A) \}^{N_I} X_I $$ \hspace{1cm} (1.21)

with

$$ N = A_{SD} / \Gamma_{tot} = 8.348 \cdot 10^{-2} . $$ \hspace{1cm} (1.22)

The values for $N_I$ and $X_I$ are listed in table 1.1.

To estimate $\Gamma_I$ and $BR_I$, we note that the form factors $V, A$ are of order

$$ M_K(V + A) \simeq -10^{-1} , \quad M_K(V - A) \simeq -4 \cdot 10^{-2} . $$ \hspace{1cm} (1.23)

From this and from the entries in the table one concludes that for the above regions $R_I$, the interference terms INT$^\pm$ are negligible in $K_{e2\gamma}$, whereas they are important in $K_{\mu2\gamma}$. Furthermore, IB is negligible for $K_{e2\gamma}$, because it is helicity suppressed as can be seen from the factor $m_l^2$ in $A_{IB}$. This term dominates however in $K_{\mu2\gamma}$.

1.3 Determination of $A(W^2)$ and $V(W^2)$

The decay rate contains two real functions

$$ F^\pm(W^2) = V(W^2) \pm A(W^2) $$ \hspace{1cm} (1.24)

as the only unknowns. In Figs. (1.1,1.2) we display contour plots for the density distributions $f_{IB}, \ldots, f_{INT^\pm}$ for $l = \mu, e$. These five terms have obviously very different Dalitz plots. Therefore, in principle, one can determine the strength of each term by choosing a suitable kinematical region of observation. To pin down $F^\pm$, it would be sufficient to measure at each photon energy the interference term INT$^\pm$. This has not yet been achieved so far, either because the contribution of INT$^\pm$ is too

---

1 This cut has been used in \( [3] \) for $K_{\mu2\gamma}$, because this kinematical region is free from $K_{\mu3}$ background. We apply it here for illustration also to the electron mode $K_{e2\gamma}$. 

8
Figure 1.1: Contour plots for $f_{ib}, \ldots, f_{int} \pm [K_{\mu2\gamma}]$. The numbering on the lines points towards increasing modulus. The normalization is arbitrary.
Figure 1.2: Contour plots for $f_{IB}, \ldots, f_{INT\pm [K_{e2z}]}$. The numbering on the lines points towards increasing modulus. The normalization is arbitrary.
small (in $K_{e2\gamma}$), or because too few events have been collected (in $K_{\mu2\gamma}$). On the other hand, from a measurement of $SD^\pm$ alone one can determine $A, V$ only up to a fourfold ambiguity:

$$SD^\pm \rightarrow \{(V, A); -(V, A); (A, V); -(A, V)\}. \quad (1.25)$$

In terms of the ratio

$$\gamma_K = A/V \quad (1.26)$$

this ambiguity amounts to

$$SD^\pm \rightarrow \{\gamma_K; 1/\gamma_K\}. \quad (1.27)$$

Therefore, in order to pin down the amplitudes $A$ and $V$ uniquely, one must measure the interference terms $INT^\pm$ as well.

1.4 Previous experiments

$K^+ \rightarrow e^+\nu_e\gamma$

The PDG uses data from two experiments [4, 7], both of which have been sensitive mainly to the $SD^+$ term in (1.13). In [7], 56 events with $E_\gamma > 100$ MeV, $E_{e^+} > 236$ MeV and $\theta_{e^+\gamma} > 120^\circ$ have been identified, whereas the later experiment [4] has collected 51 events with $E_\gamma > 48$ MeV, $E_{e^+} > 235$ MeV and $\theta_{e^+\gamma} > 140^\circ$. In these kinematical regions, background from $K^+ \rightarrow e^+\nu_e\pi^0$ is absent because $E_{e^+}^{\max}(K_{e3}) = 228$ MeV. The combined result of both experiments is [4]

$$\Gamma(SD^+)/\Gamma(K_{\mu2}) = (2.4 \pm 0.36) \cdot 10^{-5}. \quad (1.28)$$

For $SD^-$, the bound

$$\Gamma(SD^-)/\Gamma_{\text{total}} < 1.6 \cdot 10^{-4} \quad (1.29)$$

has been obtained from a sample of electrons with energies $220$ MeV $\leq E_e \leq 230$ MeV [4]. Using (1.21, 1.22), the result (1.28) leads to

$$M_K \mid V + A \mid = 0.105 \pm 0.008. \quad (1.30)$$

The bound (1.29) on the other hand implies [4]

$$| V - A | / | V + A | < \sqrt{11}, \quad (1.31)$$

from where one concludes [4] that $\gamma_K$ is outside the range $-1.86$ to $-0.54$,

$$\gamma_K \notin [-1.86, -0.54] \quad (1.32)$$

\footnote{In all four experiments [4, 5, 6, 7] discussed here and below, the form factors $A$ and $V$ have been treated as constants.}
Table 1.2: Measured branching ratios $\Gamma(K \rightarrow l\nu l\gamma)/\Gamma_{\text{total}}$. The $K_{e2\gamma}$ data are from [1, 4], the $K_{\mu2\gamma}$ data from [3, 5]. The last column corresponds [5] to the cut (1.20).

|                | SD$^+$   | SD$^-$   | INT$^+$  | SD$^-$ + INT$^-$ | total    |
|----------------|----------|----------|----------|------------------|----------|
| $K_{e2\gamma}$ | $(1.52 \pm 0.23) \cdot 10^{-5}$ | $< 1.6 \cdot 10^{-4}$ | $< 2.7 \cdot 10^{-5}$ (modulus) | $< 2.6 \cdot 10^{-4}$ (modulus) | $(3.02 \pm 0.10) \cdot 10^{-5}$ |
| $K_{\mu2\gamma}$ | $< 3 \cdot 10^{-5}$ | $< 1.6 \cdot 10^{-4}$ | $< 2.7 \cdot 10^{-5}$ (modulus) | $< 2.6 \cdot 10^{-4}$ (modulus) | $(3.02 \pm 0.10) \cdot 10^{-5}$ |

As we already mentioned, the interference terms INT$^\pm$ in $K \rightarrow e\nu_e\gamma$ are small and can hardly ever be measured. As a result of this, the amplitudes $A, V$ and the ratio $\gamma_K$ determined from $K_{e2\gamma}$ are subject to the ambiguities (1.25), (1.27).

\[ K^+ \rightarrow \mu^+\nu_\mu\gamma \]

Here, the interference terms INT$^\pm$ are nonnegligible in appropriate regions of phase space (see Figs. (1.1,1.2)). Therefore, this decay allows one in principle to pin down $V$ and $A$. The PDG uses data from two experiments [5, 8]. In [5], the momentum spectrum of the muon was measured in the region (1.20). In total $2 \pm 3.44$ SD$^+$ events have been found with $216 \text{ MeV/c} < p_\mu < 230 \text{ MeV/c}$ and $E_{\gamma} > 100 \text{ MeV}$, which leads to

\[ M_K | V + A | < 0.16 . \] (1.33)

In order to identify the effect of the SD$^-$ terms, the region $120 \text{ MeV/c} < p_\mu < 150 \text{ MeV/c}$ was searched. Here, the background from $K_{\mu3}$ decays was very serious. The authors found 142 $K_{\mu\nu\gamma}$ candidates and conclude that

\[ -1.77 < M_K (V - A) < 0.21 . \] (1.34)

The result (1.33) is consistent with (1.30), and the bound (1.34) is worse than the result (1.31) obtained from $K_{e2\gamma}$. The branching ratios which follow [5] from (1.33,1.34) are displayed in table 1.2, where we also show the $K_{e2\gamma}$ results [4, 4]. The entry SD$^-+$INT$^-$ for $K_{\mu2\gamma}$ is based on additional constraints from $K_{e2\gamma}$.

1.5 Theory

The amplitudes $A(W^2)$ and $V(W^2)$ have been worked out in the framework of various approaches, viz., current algebra, PCAC, resonance exchange, dispersion relations, . . . . For a rather detailed review together with an extensive list of references up to 1976 see [4]. Here, we concentrate on the predictions of $V, A$ in the framework of CHPT.
1.5.1 Chiral expansion to one loop

The amplitudes $A$ and $V$ have been evaluated \cite{10, 11} in the framework of CHPT to one loop. At leading order in the low-energy expansion, one has

$$A = V = 0.$$  \hspace{1cm} (1.35)

As a consequence of this, the rate is entirely given by the IB contribution at leading order. At the one-loop level, one finds

$$A = -4 \frac{F}{F} (L_9^r + L_{10}^r),$$  \hspace{1cm} (1.36)

$$V = -\frac{1}{8\pi^2} (L_9^r + L_{10}^r),$$

$$\gamma_K = 32\pi^2 (L_9^r + L_{10}^r),$$

where $L_9^r$ and $L_{10}^r$ are the renormalized low-energy couplings evaluated at the scale $\mu$ (the combination $L_9^r + L_{10}^r$ is scale independent). The vector form factor stems from the Wess-Zumino term \cite{12} which enters the low-energy expansion at order $p^4$, see Ref. \cite{2}.

Remarks:

(i) At this order in the low-energy expansion, the form factors $A, V$ do not exhibit any $W^2$-dependence. A nontrivial $W^2$-dependence only occurs at the next order in the energy expansion (two-loop effect, see the discussion below). Note that the available analyses of experimental data of $K \rightarrow l\nu\gamma$ decays \cite{7, 4, 5, 8} use constant form factors throughout.

(ii) Once the combination $L_9 + L_{10}$ has been pinned down from other processes, Eq. (1.36) allows one to evaluate $A, V$ unambiguously at this order in the low-energy expansion. Using $L_9 + L_{10} = 1.4 \cdot 10^{-3}$ and $F = F_\pi$, one has

$$M_K (A + V) = -0.097$$

$$M_K (V - A) = -0.037$$

$$\gamma_K = 0.45.$$  \hspace{1cm} (1.37)

The result for the combination $(A + V)$ agrees with (1.30) within the errors, while $\gamma_K$ is consistent with (1.32).

We display in table 1.3 the branching ratios $BR_I$ (1.21) which follow from the prediction (1.37). These predictions satisfy of course the inequalities found from experimental data (see table 1.2).
Table 1.3: Chiral prediction at order $p^4$ for the branching ratios $\Gamma(K \rightarrow l\nu l\gamma)/\Gamma_{\text{total}}$.

The cut used in the last column is given in Eq. (1.20).

|       | SD$^+$ | SD$^-$ | INT$^+$ | INT$^-$ | total  |
|-------|--------|--------|---------|---------|--------|
| $K_{e2\gamma}$ | $1.30 \cdot 10^{-9}$ | $1.95 \cdot 10^{-6}$ | $6.64 \cdot 10^{-10}$ | $-1.15 \cdot 10^{-8}$ | $2.34 \cdot 10^{-6}$ |
| $K_{\mu2\gamma}$ | $9.24 \cdot 10^{-6}$ | $1.38 \cdot 10^{-6}$ | $1.44 \cdot 10^{-3}$ | $-3.83 \cdot 10^{-5}$ | $3.08 \cdot 10^{-3}$ |

1.5.2 $W^2$-dependence of the form factors

The chiral prediction gives constant form factors at order $p^4$. Terms of order $p^6$ have not yet been calculated. They would, however, generate a nontrivial $W^2$-dependence both in $V$ and $A$. In order to estimate the magnitude of these corrections, we consider one class of $p^6$-contributions: terms which are generated by vector and axial-vector resonance exchange with strangeness [9, 13],

$$V(W^2) = \frac{V}{1 - W^2/M_{K^*}^2}, \quad A(W^2) = \frac{A}{1 - W^2/M_{K_1}^2}$$  \hspace{1cm} (1.38)

where $V, A$ are given in (1.36). We now examine the effect of the denominators in (1.38) in the region $y \geq 0.95, x \geq 0.2$ which has been explored in $K^+ \rightarrow e^+\nu e\gamma$ [4]. We put $m_e = 0$ and evaluate the rate

$$\frac{dP(x)}{dx} = \frac{N_{\text{tot}}}{\Gamma_{\text{tot}}} \int_{y=0.95}^{1} \rho_{SD^+}(x, y) dy$$  \hspace{1cm} (1.39)

where $N_{\text{tot}}$ denotes the total number of $K^+$ decays considered, and $\Gamma_{\text{tot}}^{-1} = 1.24 \cdot 10^{-8}$ sec.

The function $\frac{dP(x)}{dx}$ is displayed in Fig. (1.3) for three different values of $M_{K^*}$ and $M_{K_1}$, with $N_{\text{tot}} = 9 \cdot 10^9$. The total number of events

$$N_P = \int_{x=0.2}^{1} dP(x)$$  \hspace{1cm} (1.40)

is also indicated in each case. The difference between the dashed and the dotted line shows that the nearby singularity in the anomaly form factor influences the decay rate substantially at low photon energies. The effect disappears at $x \rightarrow 1$, where $W^2 = M_K^2 (1 - x) \rightarrow 0$. To minimize the effect of resonance exchange, the large-$x$ region should thus be considered. The low-$x$ region, on the other hand, may be used to explore the $W^2$-dependence of $V$ and of $A$. For a rather exhaustive discussion of the relevance of this $W^2$-dependence for the analysis of $K_{l2\gamma}$ decays we refer the reader to Ref. [4].
Figure 1.3: The rate $dP(x)/dx$ in (1.39), evaluated with the form factors (1.38) and $N_{\text{tot}} = 9 \cdot 10^9$. The solid line corresponds to $M_{K^*} = 890$ MeV, $M_{K_1} = 1.3$ GeV. The dashed line is evaluated with $M_{K^*} = 890$ MeV, $M_{K_1} = \infty$ and the dotted line corresponds to $M_{K^*} = M_{K_1} = \infty$. The total number of events is also indicated in each case.

1.6 Comment on tensor couplings

Bolotov et al. [14] have analyzed radiative pion decays $\pi^- \rightarrow e^- \bar{\nu}_e \gamma$ in flight ($\simeq 80$ events) in a wider kinematical region than was explored in the high-statistics experiment of Bay et al. [15] (where $\simeq 700 \pi^+ \rightarrow e^+ \nu_e \gamma$ events had been observed). The theoretical branching ratio, calculated with the standard $V - A$ coupling, differs from the measured one by more than three standard deviations. This discrepancy may be avoided by adding to the standard matrix element the amplitude of a tensorial interaction [16]. Belyaev and Kogan [17] and Voloshin [18] have pointed out, however, that in the standard model the induced tensor coupling is too small to generate the rate observed in ref. [14].

Gabrielli [19] has worked out the effect of tensor couplings for $K^+ \rightarrow l^+ \nu_l \gamma$ decays. Using the above quoted values for the form factors $A$ and $V$ and a tensor coupling of a size suggested to explain the data in Ref. [14], he finds a $\lesssim 30\%$ effect in the partial decay rates (the exact size depends on the chosen coupling, channel, decay region,...). The author then suggests that these effects may be accessible to detection at high precision experiments carried out at DAΦNE.

We wish to point out that this may be difficult for the following reason. The
calculation of the decays $K^+ \rightarrow l^+ \nu l \gamma$ presented in this section is based on the one-loop formulae for the decay matrix elements. Higher-order effects may well be sizeable, see e.g. figure [3]. There, it is explicitly seen that the effect of resonance exchange is $\simeq 30\%$ in particular regions of phase space. Therefore, in order to identify effects due to tensor couplings, one first has to pin down the contribution from higher-order effects in CHPT. This is not an easy task to achieve to the accuracy required. On the other hand, it is of course needless to say that the finding of a tensorial coupling of the size suggested in Ref. [6] would be spectacular.

1.7 Improvements at DAΦNE

Previous experiments have used various cuts in phase space in order (i) to identify the individual contributions $IB, SD^\pm, INT^\pm$ as far as possible, and (ii) to reduce the background from $K_{l3}$ decays. This background has in fact forced so severe cuts that only the upper end of the lepton spectrum remained.

The experimental possibilities to reduce background from $K_{l3}$ decays are presumably more favourable with today’s techniques. Furthermore, the annual yield of $9 \cdot 10^9 K^+$ decays at DAΦNE is more than two orders of magnitude higher than the samples which were available in [1, 3, 4, 8]. This allows for a big improvement in the determination of the amplitudes $A$ and $V$, in particular in $K_{\mu2\gamma}$ decays. It would be very interesting to pin down the combination $L_9 + L_{10}$ of the low-energy constants which occur in the chiral representation of the amplitude $A$ and to investigate the $W^2$-dependence of the form factors.
2 The decays $K^\pm \to l^\pm \nu l'^+ l'^-$

Here we consider decays where the photon turns into a lepton-antilepton pair,

\[
\begin{align*}
K^+ &\to e^+ \nu e^+ \mu^- \quad (2.1) \\
K^+ &\to \mu^+ \nu \mu^+ e^- \quad (2.2) \\
K^+ &\to e^+ \nu e^+ e^- \quad (2.3) \\
K^+ &\to \mu^+ \nu \mu^+ \mu^- \quad (2.4)
\end{align*}
\]

2.1 Matrix elements

We start with the processes (2.1) and (2.2),

\[
K^+(p) \to l^+(p_l) \nu(p_\nu) l'^+(p_1) l'^-(p_2) \quad (l, l') = (e, \mu) \text{ or } (\mu, e).
\]

The matrix element is

\[
T = -i G_F e V_{us}^* \epsilon \rho \bigg\{ F_K L^\rho - \overline{H}_\rho l_\mu \bigg\}
\]

where

\[
\begin{align*}
L^\rho &= m_l \overline{\pi}(p_\nu) (1 + \gamma_5) \left\{ \frac{2p^\rho - q^\rho}{2pq - q^2} - \frac{2p_1^\rho + q_1^\rho}{2p_1 q + q^2} \right\} v(p_l) \\
\overline{H}^{q \mu} &= i V_1 e^{\mu \rho \alpha \beta} q_\alpha p_\beta - A_1(q W g^{\rho \mu} - W^\rho q^\mu) \\
&\quad - A_2(q^2 g^{\rho \mu} - q^\rho q^\mu) - A_4(q W q^\rho - q^2 W^\rho) W^\mu
\end{align*}
\]

with

\[
A_4 = \frac{2 F_K}{M_K^2 - W^2} \frac{F_K^V(q^2)}{q^2} - \frac{1}{q^2} + A_3.
\]

The form factors $A_1(q^2, W^2)$, $V_1(q^2, W^2)$ are the ones defined in appendix C. $F_K^V(q^2)$ is the electromagnetic form factor of the $K^+$. Finally the quantity $\epsilon^\mu$ stands for

\[
\epsilon^\mu = \frac{e}{q^2} \overline{\pi}(p_2) \gamma^\mu v(p_1),
\]

and the four-momenta are

\[
q = p_1 + p_2, \quad W = p_l + p_\nu = p - q
\]

such that $q^\mu \epsilon^\mu = 0$.

In order to obtain the matrix element for (2.3) and (2.4),

\[
K^+(p) \to l^+(p_l) \nu(p_\nu) l'^+(p_1) l'^-(p_2),
\]

\[
(2.11)
\]
one identifies \( m_l \) and \( m'_l \) in (2.3) and subtracts the contribution obtained from interchanging \( p_1 \leftrightarrow p_l \):

\[
(p_1, p_l) \rightarrow (p_l, p_1) \\
q \rightarrow p_1 + p_2 \\
W \rightarrow p - q = p_\nu + p_1. \tag{2.12}
\]

### 2.2 Decay distributions

The decay width is given by

\[
d\Gamma = \frac{1}{2M_K(2\pi)^8} \sum_{\text{spins}} |T|^2 d_{LIPS}(p; p_l, p_\nu, p_1, p_2) \tag{2.13}
\]

and the total rate is the integral over this for the case \( l \neq l' \). For the case \( l = l' \) the integral has to be divided by the factor 2 for two identical particles in the final state.

We first consider the case where \( l \neq l' \) and introduce the dimensionless variables

\[
x = \frac{2pq}{M_K^2}, \quad y = \frac{2pp}{M_K^2}, \quad z = \frac{q^2}{M_K^2}, \quad r_l = \frac{m_l^2}{M_K^2}, \quad r'_l = \frac{m'_l^2}{M_K^2}. \tag{2.14}
\]

Then one obtains, after integrating over \( p_1 \) and \( p_2 \) at fixed \( q^2 \) [20],

\[
d\Gamma_{K^+l^+l'^-l'^-} = \alpha^2 G_F^2 |V_{us}|^2 M_K^5 F(z, r'_l) \left\{ \sum_{\text{spins}} T^\mu \overline{T}^\nu \right\} dxdydz
\]

\[
F(z, r'_l) = \frac{1}{192\pi^3 z} \left\{ 1 + 2r'_l \sqrt{1 - 4r'_l z} \right\} \overline{T}^\mu = M_K^{-2} \left\{ F_K l'^\mu - \overline{H}^\mu l_\nu \right\}. \tag{2.15}
\]

This result allows one to evaluate, e.g., the distribution \( d\Gamma/dz \) of produced \( l'^+l'^- \) pairs rather easily. The kinematically allowed region is

\[
4r'_l \leq z \leq 1 + r_l - 2\sqrt{r_l} \\
2\sqrt{z} \leq x \leq 1 + z - r_l \\
A - B \leq y \leq A + B \tag{2.16}
\]

with

\[
A = \frac{(2 - x)(1 + z + r_l - x)}{2(1 + z - x)} \\
B = \frac{(1 + z - x - r_l)\sqrt{x^2 - 4z}}{2(1 + z - x)}. \tag{2.17}
\]
The case \( l = l' \) is slightly more elaborate. We feel that it does not make sense to display the term \( \sum_{spins} |T|^2 \) because it is of considerable complexity in the general case when all the form factors \( A_i, V_1 \) and \( F^K_V \) are \( q^2 \) and \( W^2 \) dependent. The expression together with the Monte Carlo program to do the phase space integrals is available on request from the authors.

### 2.3 Theory

The form factors \( A_i, V_1 \) and \( F^K_V \) have been discussed in all kinds of models, Vector Meson Dominance, hard meson, etc.. For a discussion see Ref. [9]. We will restrict ourselves to the predictions in the framework of CHPT.

To leading order we have

\[
\begin{align*}
V_1 &= 0 \\
A_1 &= A_2 = A_3 = 0 .
\end{align*}
\]

We also have \( F^K_V = 1 \). The rate here is entirely given by the inner Bremsstrahlung contribution. At the one-loop level several form factors get non-zero values [11]

\[
\begin{align*}
V_1 &= -\frac{1}{8\pi^2 F} \\
A_1 &= -\frac{4}{F}(L'_9 + L'_{10}) \\
A_2 &= -\frac{2F_K(F^K_V(q^2) - 1)}{q^2} \\
A_3 &= 0 \\
F^K_V(q^2) &= 1 + H_{\pi\pi}(q^2) + 2H_{KK}(q^2) .
\end{align*}
\]

These results obey the current algebra relation of Ref. [9]. The function \( F^K_V(q^2) \) does, however, deviate somewhat from the linear parametrization often used. The function \( H(t) \) is defined in appendix [3].

The fact that the form factors at next-to-leading order could be written in terms of the kaon electromagnetic form factor in a simple way is not true anymore at the \( p^6 \) level. The Lagrangian at order \( p^6 \) contains a term of the form

\[
\text{tr} \left\{ D_\alpha F_L^{\alpha\mu} U^\dagger D^\beta F_R^{\beta\mu} U \right\}
\]

that contributes to \( A_2 \) and \( A_3 \) but not to the kaon electromagnetic form factor, \( F^K_V(q^2) \).

### 2.4 Numerical results

We have calculated the rates for a few cuts, including those given in the literature. For the case of unequal leptons, the results are given in table 2.1 for the decay \( K^+ \rightarrow \)
Table 2.1: Theoretical values for the branching ratios for the decay $K^+ \rightarrow \mu^+\nu e^+e^-$ for various cuts.

| Cut                        | Tree Level | CHPT Form Factors |
|---------------------------|------------|-------------------|
| Full Phase Space          | $2.49 \cdot 10^{-5}$ | $2.49 \cdot 10^{-5}$ |
| $z \leq 10^{-3}$          | $2.07 \cdot 10^{-5}$ | $2.07 \cdot 10^{-5}$ |
| $z \geq 10^{-3}$          | $4.12 \cdot 10^{-6}$ | $4.20 \cdot 10^{-6}$ |
| $z \geq (20 \text{ MeV}/M_K)^2$ | $3.15 \cdot 10^{-6}$ | $3.23 \cdot 10^{-6}$ |
| $z \geq (140 \text{ MeV}/M_K)^2$ | $4.98 \cdot 10^{-8}$ | $8.51 \cdot 10^{-8}$ |
| $x \geq 40 \text{ MeV}/M_K$ | $1.58 \cdot 10^{-5}$ | $1.58 \cdot 10^{-5}$ |

$\mu^+\nu e^+e^-$. These include the cuts used in Refs. [20] and [21], $x \geq 40 \text{ MeV}/M_K$ and $z \geq (140 \text{ MeV}/M_K)^2$, respectively. It can be seen that for this decay most of the branching ratio is generated at very low electron-positron invariant masses. As can be seen from the result for the cuts used in Ref. [21], the effect of the structure dependent terms is most visible at high invariant electron-positron invariant mass. Our calculation, including the effect of the form factors agrees well with their data. We disagree, however, with the numerical result obtained by Ref. [20] by about an order of magnitude.

For the decay $K^+ \rightarrow e^+\nu \mu^+\mu^-$, we obtain for the tree level or IB contribution a branching ratio

$$BR_{IB}(K^+ \rightarrow e^+\nu \mu^+\mu^-) = 3.06 \cdot 10^{-12}$$

(2.21)

and, including the form factors,

$$BR_{total}(K^+ \rightarrow e^+\nu \mu^+\mu^-) = 1.12 \cdot 10^{-8}.$$ 

(2.22)

Here the structure dependent terms are the leading-contribution since the inner Bremsstrahlung contribution is helicity suppressed as can be seen from the factor $m_l$ in $\Sigma_{\mu}$.

For the decays with identical leptons we obtain for the muon case a branching ratio of

$$BR_{total}(K^+ \rightarrow \mu^+\nu \mu^+\mu^-) = 1.35 \cdot 10^{-8}$$

(2.23)

for the full phase space including the effects of the form factors. The inner Bremsstrahlung or the tree level branching ratio for this decay is

$$BR_{IB}(K^+ \rightarrow \mu^+\nu \mu^+\mu^-) = 3.79 \cdot 10^{-9}.$$ 

(2.24)

For the decay with two positrons and one electron the integration over full phase space for the tree level results is very sensitive to the behaviour for small pair masses. We have given the tree level and the full prediction, including form factor effects in
Table 2.2: Theoretical values for the branching ratios for the decay $K^+ \rightarrow e^+\nu e^-e^-$ for various cuts.

| Cut Condition                  | Tree Level | Form Factors as Given by CHPT |
|--------------------------------|------------|--------------------------------|
| Full phase space               | $\approx 4 \cdot 10^{-9}$ | $1.8 \cdot 10^{-7}$ |
| $z, z_1 \geq 10^{-3}$         | $3.0 \cdot 10^{-10}$ | $1.22 \cdot 10^{-7}$ |
| $z, z_1 \geq (50 \text{ MeV}/M_K)^2$ | $5.2 \cdot 10^{-11}$ | $8.88 \cdot 10^{-8}$ |
| $z, z_1 \geq (140 \text{ MeV}/M_K)^2$ | $2.1 \cdot 10^{-12}$ | $3.39 \cdot 10^{-8}$ |

The values for the masses used are those of $K^+$ and $\pi^+$. For $L_9$ and $L_{10}$ we used the values given in table 1 in Ref. [2], $L_r^9(M_\rho) = 6.9 \cdot 10^{-3}$, $L_r^{10}(M_\rho) = -5.5 \cdot 10^{-3}$.

2.5 Present experimental status

Only decays with an electron positron pair in the final state, decays (2.2) and (2.3), have been observed.

Both have been measured in the same experiment [21]. The decay $K^+ \rightarrow \mu^+\nu e^+e^-$ was measured with a branching ratio of $(1.23 \pm 0.32) \cdot 10^{-7}$ with a lower cut on the electron positron invariant mass of 140 MeV. The measurement is compatible with our calculation including the form factor effects for the relevant region of phase space. This measurement was then extrapolated [21] using the result of [20] to the full phase space. Since we disagree with that calculation, we also disagree with the extrapolation.

In the same experiment, 4 events of the type $K^+ \rightarrow e^+\nu e^-e^-$ were observed where both electron positron pair invariant masses were above 140 MeV. This corresponds to a branching ratio for this region of phase space of $(2.8^{+2.8}_{-1.4}) \cdot 10^{-8}$. This result is compatible within errors with our calculation, see table 2.2. The matrix element of Ref. [20] was again used for the extrapolation to full phase space [21]. Apart from our numerical disagreement, the calculation of Ref. [20] was for the case of non-identical leptons and cannot be applied here.

For the decay $K^+ \rightarrow \mu^+\nu\mu^+\mu^-$ an upper limit of $4.1 \cdot 10^{-7}$ exists [22]. This upper limit is compatible with our theoretical result, Eq. (2.23).
The decay $K^+ \rightarrow e^+\nu\mu^+\mu^-$ has not been looked for so far and should be within the capabilities of DAΦNE given the branching ratio predicted in the previous subsection. This decay proceeds almost entirely through the structure dependent terms and is as such a good test of our calculation.

2.6 Improvements at DAΦNE

The decays discussed in this subsection, $K^+ \rightarrow l^+\nu l^+l^-$, are complementary to the decays $K^+ \rightarrow l^+\nu\gamma$. As was the case for the analogous decay, $\pi^+ \rightarrow e^+\nu e^+e^-$ [23], it may be possible to explore phase space more easily with this process than with $K^+ \rightarrow l^+\nu\gamma$ to resolve ambiguities in the form factors.

As can be seen from our predictions, tables 2.1 and 2.2, all the decays considered in this subsection should be observable at DAΦNE. Large improvements in statistics are possible since less severe cuts than those used in the past experiments should be possible. In the decays with a $\mu^+\mu^-$ pair and the decay $K^+ \rightarrow e^+\nu e^+e^-$ the effects of the form factors are already large in the total rates and should be easily visible at DAΦNE. In the decay $K^+ \rightarrow \mu^+\nu e^+e^-$ most of the total rate is for small invariant mass of the pair and is given by the inner Bremsstrahlung contribution. There are, however, regions of phase space where the form factor effects are large and DAΦNE should have enough statistics to be able to study these regions.
3 \( K_{l3} \) decays

The decay channels considered in this subsection are

\[
K^+(p) \rightarrow \pi^0(p')l^+(p_l)\bar{\nu}_l(p_{\nu}) \quad [K_{l3}^+] \quad (3.1)
\]
\[
K^0(p) \rightarrow \pi^-(p')l^+(p_l)\bar{\nu}_l(p_{\nu}) \quad [K_{l3}^0] \quad (3.2)
\]

and their charge conjugate modes. The symbol \( l \) stands for \( \mu \) or \( e \). We do not consider electromagnetic corrections and correspondingly set \( \alpha = 0 \) throughout this subsection.

3.1 Matrix elements and kinematics

The matrix element for \( K_{l3}^+ \) has the general structure

\[
T = \frac{G_F}{\sqrt{2}} V_{us} \ell^\mu F^+(p',p) \quad (3.3)
\]

with

\[
\ell^\mu = \bar{u}(p_{\nu})\gamma^\mu(1-\gamma_5)v(p_l)
\]
\[
F^+(p',p) = \langle \pi^0(p') | V^{4-i5}(0) | K^+(p) \rangle
\]
\[
= \frac{1}{\sqrt{2}}[\langle p' + p \rangle_\mu f^0_+(t) + \langle p - p' \rangle_\mu f^0_-(t)]. \quad (3.4)
\]

To obtain the matrix element for \( K_{l3}^0 \), one replaces \( F^+_\mu \) by

\[
F^0_\mu(p',p) = \langle \pi^-(p') | V^{4-i5}(0) | K^0(p) \rangle
\]
\[
= \langle p' + p \rangle_\mu f^0_+(t) + \langle p - p' \rangle_\mu f^0_-(t). \quad (3.5)
\]

The processes (3.1) and (3.2) thus involve the four \( K_{l3} \) form factors \( f_{\pm}^{K\pi}(t) \), \( f_{\pm}^{K\pi^0}(t) \) which depend on

\[
t = (p' - p)^2 = (p_l + p_{\nu})^2, \quad (3.6)
\]

the square of the four momentum transfer to the leptons.

Let \( f_{\pm}^{K\pi} = f_{\pm}^{K\pi^0} \) or \( f_{\pm}^{K\pi^0} \). \( f_{\pm}^{K\pi} \) is referred to as the vector form factor, because it specifies the \( P \)-wave projection of the crossed channel matrix elements \( <0 | V^{4-i5}(0) | K^+, \pi^0 \) in \( > \). The \( S \)-wave projection is described by the scalar form factor

\[
f^0_0(t) = f^0_+(t) + \frac{t}{M^2_K - M^2_{\pi^0}} f^0_-(t). \quad (3.7)
\]

Analyses of \( K_{l3} \) data frequently assume a linear dependence

\[
f^{K\pi}_{+,0}(t) = f^{K\pi}_{+,0}(0) \left[ 1 + \lambda_{+,0} \frac{t}{M^2_{\pi^0}} \right]. \quad (3.8)
\]
For a discussion of the validity of this approximation see \[24, 3\] and references cited therein. Eq. (3.8) leads to a constant $f_{K\pi}^{-}(t)$,

$$f_{K\pi}^{-}(t) = f_{K\pi}^{-}(0) = f_{K\pi}^{+}(0)(\lambda_0 - \lambda_+) \frac{M_K^2 - M_{\pi}^2}{M_{\pi}^2}. \quad (3.9)$$

The form factors $f_{K\pi}^{\pm}(t)$ are analytic functions in the complex $t$-plane cut along the positive real axis. The cut starts at $t = (M_K + M_{\pi})^2$. In our phase convention, the form factors are real in the physical region

$$m_t^2 \leq t \leq (M_K - M_{\pi})^2. \quad (3.10)$$

The kinematics of (spin averaged) $K_{l3}$ decays needs two variables, for which we choose

$$y = 2p_{pl}/M_K^2, \quad z = 2pp'/M_K^2 = (-t + M_{\pi}^2 + M_K^2)/M_K^2. \quad (3.11)$$

In the $K$ rest frame, $y$ ($z$) is proportional to the charged lepton (pion) energy,

$$y = 2E_l/M_K, \quad z = 2E_\pi/M_K. \quad (3.12)$$

The physical region for $y$ and $z$ is

$$2\sqrt{r_l} \leq y \leq 1 + r_l - r_{\pi},$$

$$A(y) - B(y) \leq z \leq A(y) + B(y)$$

$$A(y) = (2 - y)(1 + r_l + r_{\pi} - y)/[2(1 + r_l - y)]$$

$$B(y) = \sqrt{y^2 - 4r_l(1 + r_l - r_{\pi} - y)/[2(1 + r_l - y)]}$$

$$r_l = m_l^2/M_K^2, r_{\pi} = M_{\pi}^2/M_K^2. \quad (3.13)$$

or, equivalently,

$$2\sqrt{r_{\pi}} \leq z \leq 1 + r_{\pi} - r_l$$

$$C(z) - D(z) \leq y \leq C(z) + D(z)$$

$$C(z) = (2 - z)(1 + r_{\pi} + r_l - z)/[2(1 + r_{\pi} - z)]$$

$$D(z) = \sqrt{z^2 - 4r_{\pi}(1 + r_{\pi} - r_l - z)/[2(1 + r_{\pi} - z)]. \quad (3.14)$$

### 3.2 Decay rates

The differential decay rate for $K_{l3}^+$ is given by

$$d\Gamma = \frac{1}{2M_K(2\pi)^3} \sum_{\text{spins}} |T|^2 dLIPS(p; p_l, p_\nu, p') \quad (3.15)$$
The Dalitz plot density

\[ \rho(y, z) = \frac{d^2\Gamma}{dydz} = \frac{M_K}{256\pi^3} \sum_{spins} |T|^2 \] (3.16)

is a Lorentz invariant function which contains \( f_\pm^{K^+\pi^0} \) in the following form,

\[ \rho(y, z) = \frac{M_K^5 G_F^2 |V_{us}|^2}{256\pi^3} \left[ \frac{A(f_+^{K^+\pi^0})^2 + B f_+^{K^+\pi^0} f_-^{K^+\pi^0} + C (f_-^{K^+\pi^0})^2}{256\pi^3} \right] \] (3.17)

with

\[
A(y, z) = 4(z + y - 1)(1 - y) + r_l[4y + 3z - 3] - 4r_\pi + r_l(r_\pi - r_l)
\]

\[
B(y, z) = 2r_l(3 - 2y - z + r_l - r_\pi)
\]

\[
C(y, z) = r_l(1 + r_\pi - z - r_l).
\] (3.18)

The quantities \((A, B, C)\) are related to the ones quoted by the PDG [3] by

\[(A, B, C) = \frac{8}{M_K^2} (A, B, C)_{PDG}. \] (3.19)

To obtain the rate for \(K^0_{l3}\), one replaces in (3.17) \( f_\pm^{K^+\pi^0} \) by \( \sqrt{2} f_\pm^{K^0\pi^-} \).

For convenience we also display the \(K_{\mu3}/K_{e3}\) rates evaluated in the approximation (3.8) for the form factors,

\[
\Gamma(K_{\mu3})/\Gamma(K_{e3}) = \frac{0.645 + 2.087\lambda_+ + 1.464\lambda_0 + 3.375\lambda^2_+ + 2.573\lambda^2_0}{1 + 3.457\lambda_+ + 4.783\lambda^2_+},
\]

\[
\Gamma(K_{l3}^0)/\Gamma(K_{e3}) = \frac{0.645 + 2.086\lambda_+ + 1.459\lambda_0 + 3.369\lambda^2_+ + 2.560\lambda^2_0}{1 + 3.456\lambda_+ + 4.776\lambda^2_+}. \] (3.20)

We have used the physical masses [3] in evaluating these ratios and \(M_{\pi^+}\) to scale the slope in both cases. The terms linear and quadratic in \(\lambda_0\) are proportional to \(m_t^2\) and therefore strongly suppressed in the electron case. We do not include them in the denominators, because these coefficients are smaller than 10\(^{-4}\). The interference term \(\lambda_0\lambda_+\) is absent by angular momentum conservation. Furthermore, one has

\[
\int dy \ dz A(y, z) = \begin{cases} 
0.0623 & [K_{\mu3}^+] \\
0.0606 & [K_{l3}^0]
\end{cases}.
\] (3.21)

### 3.3 Determination of the \(K_{l3}\) form factors

Measurements of the Dalitz plot distribution (3.17) of \(K_{\mu3}\) data allow one in principle to pin down the form factors (up to a sign) in the range \(m_{\mu}^2 \leq t \leq (M_K - M_\pi)^2\). Measuring the \(K_{\mu3}/K_{e3}\) branching ratio and then using (3.20) gives a relationship
between $\lambda_+$ and $\lambda_0$ which is valid in the approximation (3.8). Furthermore, muon polarization experiments measure the weighted average of the ratio $f_{K^\pi}(t)/f_{K^\pi}^*(t)$ over the $t$ range of the experiment [4, 23]. On the other hand, the electron modes $K_{e3}$ are sensitive to $f_{K^\pi}^*$ only, because the other contributions are suppressed by the factor $(m_e/M_K)^2 \simeq 10^{-6}$, see eqs. (3.17), (3.18).

Isospin breaking effects in $f_{K^\pi}^{*0}(0)$ and $f_{K^0\pi^+}(0)$ play a central role in the determination of the Kobayashi-Maskawa matrix element $V_{us}$ from $K_{e3}$ data, see [26] for a detailed discussion of this point. In the following we concentrate on the measurement of the slopes $\lambda_{+0}$.

### 3.4 Previous measurements

We refer the reader to the 1982 version of the PDG [27] for a critical discussion of the wealth of experimental information on $\lambda_{+0}^K$. Here we content ourselves with a short summary.

**$K_{e3}$-experiments**

The $\lambda_+$ values obtained are fairly consistent. The average values are

$$
\begin{align*}
K_{e3}^+ : \lambda_+ & = 0.028 \pm 0.004 \text{ Ref.[3]} \\
K_{e3}^0 : \lambda_+ & = 0.030 \pm 0.0016 \text{ Ref.[3]}.
\end{align*}
$$

**$K_{\mu3}$-experiments**

The result by Donaldson et al. [28]

$$
\begin{align*}
\lambda_+ & = 0.030 \pm 0.003 \\
\lambda_0 & = 0.019 \pm 0.004
\end{align*}
$$

dominates the statistics in the $K_{\mu3}^0$ case. The $\lambda_+$ value (3.23) is consistent with the $K_{e3}$ value (3.22). However, the situation concerning the slope $\lambda_0$ is rather unsatisfactory, as the following (chronological) list illustrates.

$$
\lambda_0 = \begin{cases} 
0.0341 \pm 0.0067 & \text{[29]} \\
0.050 \pm 0.008 & \text{[30]} \\
0.039 \pm 0.010 & \text{[31]} \\
0.047 \pm 0.009 & \text{[32]} \\
0.025 \pm 0.019 & \text{[33]} \\
0.019 \pm 0.004 & \text{[28]}
\end{cases}
$$

The $\chi^2$ fit to the $K_{\mu3}^0$ data yields $\lambda_+ = 0.034 \pm 0.005$, $\lambda_0 = 0.025 \pm 0.006$ with a $\chi^2/DF = 88/16$ [27, p.76]! The situation in the charged mode $K_{\mu3}^+$ is slightly better [27].

3Please note that the most recent measurements of $\lambda_{+0}$ go back to 1981 [3]!
3.5 Theory

The theoretical prediction of $K_{l3}$ form factors has a long history, starting in the sixties with the current algebra evaluation of $f_{K^+}^\pi$. For an early review of the subject and for references to work prior to CHPT evaluations of $f_\pm$ we refer the reader to [34] (see also Ref.[35]). Here we concentrate on the evaluation of the form factors in the framework of CHPT. We restrict our consideration to the isospin symmetry limit $m_u = m_d$, as a result of which one has

$$f_{\pm,0}^{K_0}\pi^- (t) = f_{\pm,0}^{K^+}\pi^0 (t) \equiv f_{\pm,0}(t) ; \quad m_u = m_d \, . \quad (3.25)$$

3.5.1 Chiral prediction at one-loop order

In Ref. [24], the vector current matrix elements $< M' | q\gamma^\mu \frac{\Lambda}{2} q | M >$ have been calculated up to and including terms of order $t = (p' - p)^2$ and of order $m_u, m_d$ and $m_s$ in the invariant form factors. For reasons which will become evident below, we consider here, in addition to the $K_{l3}$ form factors, also the electromagnetic form factor of the pion

$$< \pi^+ (p') | V^\mu_{em} (0) | \pi^+ (p) > = (p' + p)^\mu F_{V}^\pi(t). \quad (3.26)$$

The low-energy representation for $F_{V}^\pi(t)$ [24, 36] and $f_+(t)$ [24] reads

$$F_{V}^\pi(t) = 1 + 2H_{\pi\pi}(t) + H_{KK}(t)$$

$$f_+(t) = 1 + \frac{3}{2}H_{K\pi}(t) + \frac{3}{2}H_{K\eta}(t). \quad (3.27)$$

The quantity $H(t)$ is a loop function displayed in appendix [3]. It contains the low-energy constant $L_9$. The indices attached to $H(t)$ denote the masses running in the loop.

Since $L_9$ is the only unknown occurring in $F_{V}^\pi(t)$ and in $f_+(t)$, we need experimental information on the slope of one of these two form factors to obtain a parameter-free low-energy representation of the other.

The analogous low-energy representation of the scalar form factor is

$$f_0(t) = 1 + \frac{1}{8F^2} \left( 5t - 2\Sigma_{K\pi} - 3\frac{\Delta_{K\pi}^2}{t} \right) \tilde{J}_{K\pi}(t)$$

$$+ \frac{1}{24F^2} \left( 3t - 2\Sigma_{K\pi} - \frac{\Delta_{K\pi}^2}{t} \right) \tilde{J}_{K\eta}(t)$$

$$+ \frac{t}{\Delta_{K\pi}} \left( \frac{F_K}{F_{\pi}} - 1 \right). \quad (3.28)$$
Figure 3.1: The vector and scalar form factors $f_+(t)$ and $f_0(t)$.

The function $\bar{J}(t)$ is listed in appendix A and $\Sigma_{K\pi}$ and $\Delta_{K\pi}$ stand for
\[
\Sigma_{K\pi} = M_K^2 + M_\pi^2 \\
\Delta_{K\pi} = M_K^2 - M_\pi^2.
\] (3.29)

The measured value $F_K/F_\pi = 1.22 \pm 0.01$ may be used to obtain a parameter-free prediction of the scalar form factor $f_0(t)$.

### 3.5.2 Momentum dependence of the vector form factor

In the spacelike interval $\sqrt{-t} < 350$ MeV the low-energy representation (3.27) for the electromagnetic form factor $F_V^\pi(t)$ is very well approximated by the first two terms in the Taylor series expansion around $t = 0$,
\[
F_V^\pi(t) = 1 + \frac{1}{6} < r^2 >^\pi_V t + \cdots.
\] (3.30)

Likewise, the linear approximation
\[
f_+(t) = f_+(0) \left\{ 1 + \frac{1}{6} < r^2 >^K_V t + \cdots \right\}
\] (3.31)
reproduces the low-energy representation (3.27) very well, see Fig. 3.1. This is in agreement with the observed Dalitz plot distribution, which is consistent with a form factor linear in $t$. The charge radii are
\[
<r^2>^\pi_V = \frac{12 L_9^r}{F^2} - \frac{1}{32 \pi^2 F^2} \left\{ 2 \ln \frac{M_\pi^2}{\mu^2} + \ln \frac{M_K^2}{\mu^2} + 3 \right\}
\]
\[
<r^2>_{V}^{K\pi} = <r^2>_{V}^{\pi} - \frac{1}{64\pi^2 F^2} \left\{ 3h_1 \left( \frac{M^2_{\pi}}{M^2_K} \right) + 3h_1 \left( \frac{M^2_{\eta}}{M^2_K} \right) + \frac{5}{2} \ln \frac{M^2_K}{M^2_\pi} + \frac{3}{2} \ln \frac{M^2_{\eta}}{M^2_K} - 6 \right\}
\]
(3.32)

where
\[
h_1(x) = \frac{1}{2} \frac{(x^3 - 3x^2 - 3x + 1)}{(x-1)^3} \ln x + \frac{1}{2} \frac{(x+1)}{(x-1)}^2 - \frac{1}{3}.
\]
(3.33)

To evaluate these relations numerically, we use the measured charge radius of the pion:
\[
<r^2>_{V}^{\pi} = 0.439 \pm 0.008 \text{fm}^2 \quad [37]
\]
(3.34)
as input and obtain the prediction
\[
\lambda_+ = \frac{1}{6} M^2_{\pi} <r^2>_{V}^{K\pi} = 0.031
\]
(3.35)
in agreement with the experimental results \((3.22), (3.23)\). From this (and from the considerably more detailed discussion in Ref. [24]), one concludes, in agreement with other theoretical investigations \([38]\), that the measured charge radii \(r^2 >_{V}^{\pi}\) and \(r^2 >_{V}^{K\pi}\) are consistent with the low-energy prediction.

### 3.5.3 Momentum dependence of the scalar form factor. Dashen-Weinstein and Callan-Treiman relations

In the physical region of \(K_{13}\) decay the low-energy representation (3.28) for the scalar form factor is approximated by the linear formula
\[
f_0(t) = f_+(0) \left\{ 1 + \frac{1}{6} <r^2>_{S}^{K\pi} t + \cdots \right\}
\]
(3.36)
to within an accuracy of 1%. (See Fig. [3.1].) The curvature generated by higher-order terms is also expected to be negligible in the physical region of the decay [24]. For the slope \(<r^2>_{S}^{K\pi}\) one obtains
\[
<r^2>_{S}^{K\pi} = \frac{6}{M^2_K - M^2_\pi} \left( \frac{F_K}{F_\pi} - 1 \right) + \delta_2 + O(\hat{m}, m_s)
\]
\[
\delta_2 = \frac{1}{192\pi^2 F^2} \left\{ 15h_2 \left( \frac{M^2_\pi}{M^2_K} \right) + 19M^2_K + 3M^2_\eta \right\} h_2 \left( \frac{M^2_{\eta}}{M^2_K} \right) - 18
\]
(3.37)

\(^4\) We do not quote an error for the result (3.35), because one should estimate higher-order chiral corrections for this purpose.
Figure 3.2: The normalized slopes of the vector and the scalar form factors. Curve 1: the normalized slope $M^2_\pi + df_+(t)/dt$. Curve 2: the normalized slope $M^2_\pi, df_0(t)/dt$. Near the $\pi K$ threshold $t_0 = (M_K + M_\pi)^2$, the vector form factor behaves as $f_+(t) = f_+(t_0) + O[(t - t_0)]$, whereas $f_0(t) = f_0(t_0) + O[\sqrt{t - t_0}]$. The slope of the scalar form factor is therefore singular at $t = (M_K + M_\pi)^2$.

where

$$
\begin{align*}
    h_2(x) &= \frac{3}{2} \left( \frac{1 + x}{1 - x} \right)^2 + \frac{3x(1 + x)}{(1 - x)^3} \ln x, \\
    h_2(x) &= h_2 \left( \frac{1}{x} \right), \quad h_2(1) = 1, \\
    \hat{m} &= (m_u + m_d)/2 .
\end{align*}
$$

(3.38)

This (parameter-free) prediction is a modified version of the Dashen-Weinstein relation [39], which results if the nonanalytic contribution $\delta_2$ is dropped. Dashen, Li, Pagels and Weinstein [40] were the first to point out that the low-energy singularities generated by the Goldstone bosons affect this relation. The modified relation is formulated as a prediction for the slope of $f_0(t)$ at the unphysical point $t_1 = M_K^2 + M_\pi^2$. Their expression for this slope however has two shortcomings: (i) it does not account for all corrections of order $\mathcal{M}$; (ii) The slope at $t_1$ differs substantially from the slope in the physical region of the decay [24, 41], see Fig. 3.2.

Algebraically, the correction $\delta_2$ is of the same order in the low-energy expansion as the term involving $F_K/F_\pi - 1$. Numerically, the correction is however small: $\delta_2$ reduces the prediction by 11%. With $F_K/F_\pi = 1.22 \pm 0.01$ the low-energy theorem (3.37) implies

$$
< r^2 >_{S^\pi} = 0.20 \pm 0.05 \text{fm}^2
$$
\[ \lambda_0 = \frac{1}{6} M_{\pi^+}^2 < r^2 >_{\pi^0}^{K^0} = 0.017 \pm 0.004 \quad (3.39) \]

where the error is an estimate of the uncertainties due to higher-order contributions. The prediction (3.39) is in agreement with the high-statistics experiment \cite{28} quoted in (3.23) but in flat disagreement with some of the more recent data listed in (3.24).

In the formulation of Dashen and Weinstein \cite{39}, the Callan-Treiman relation \cite{42} states that the scalar form factor evaluated at \( t = M_K^2 - M_\pi^2 \) differs from \( F_K/F_\pi \) only by terms of order \( m_u, m_d \): the quantity

\[ \Delta_{CT} = f_0(M_K^2 - M_\pi^2) - \frac{F_K}{F_\pi} \quad (3.40) \]

is of order \( \hat{m} \). Indeed, the low-energy representation (3.28) leads to

\[ \Delta_{CT} = -\frac{M_\pi^2}{2F^2} \left\{ \bar{J}_{K\pi}(M_K^2 - M_\pi^2) + \frac{1}{3} \bar{J}_{K\eta}(M_K^2 - M_\pi^2) \right\} + O(\hat{m}m_s) \quad (3.41) \]

Numerically, \( \Delta_{CT} = -3.5 \cdot 10^{-3} \). The Callan-Treiman relation should therefore hold to a very high degree of accuracy. If the form factor is linear from \( t = 0 \) to \( t = M_K^2 - M_\pi^2 \) then the slope must be very close to

\[ \lambda_{CT} = \frac{M_\pi^+}{M_K^2 - M_\pi^2} \left( \frac{F_K}{F_\pi} - 1 \right) = 0.019, \quad (3.42) \]

in agreement with (3.39) and with the experimental result of Ref. \cite{28}, but in disagreement with, e.g., the value found in Ref. \cite{30}. We see no way to reconcile the value \( \lambda_0 = 0.050 \) with chiral symmetry.

### 3.6 Comment on tensor couplings

S.A. Akimenko et al. \cite{43} have investigated the general form of the matrix element for \( K_{e3} \) decays, obtained by adding scalar and tensor couplings to the standard \( V-A \) interaction. Analyzing the Dalitz-plot distribution of \( 3.2 \cdot 10^4 K^+ \to \pi^0 e^+\nu_e \) events, they find that the presence of scalar and tensor couplings or nonlinearities in the form factor \( f_+ \) cannot be excluded. DAΦNE may be an ideal place to check this claim \((\approx 4 \cdot 10^8 K^+ \to \pi^0 e^+\nu_e \) events in one year). However, the same proviso as in the case of radiative \( K_{l2} \) decays should be made (see subsection (4.6)): before any firm conclusion can be drawn, one has to estimate the effect of higher-order terms in the chiral calculation. In the present case this may be less difficult to achieve than in radiative kaon decays, as only one form factor comes into play, which, in addition, depends on one kinematical variable only.
Table 3.1: Rates of $K_{l3}$ decays. The number of events in the third column corresponds to those data which are of relevance for the determination of the slope $\lambda_0$ of the scalar form factor.

| Event | Branching Ratio | Particle Data Group | DAΦNE 1 year | Improvement |
|-------|-----------------|---------------------|--------------|-------------|
| $K^+ \rightarrow \pi^0 \mu^+ \nu_\mu$ | $3.18 \cdot 10^{-2}$ | $10^9$ | $3 \cdot 10^5$ | $3 \cdot 10^4$ |
| $K_L \rightarrow \pi^\pm \mu^\mp \nu$ | $27 \cdot 10^{-2}$ | $4 \cdot 10^6$ | $3 \cdot 10^8$ | 70 |

3.7 Improvements at DAΦNE

DAΦNE provides the opportunity to improve our knowledge of $K_{l3}$ decays in a very substantial manner - in particular, it should be possible to clarify the issue of the slope $\lambda_0$ of the scalar form factor $f_0$. To illustrate, we compare in table 3.1 the hitherto obtained number of events (third column) with the expected ones at DAΦNE (fourth column). The last column displays the remarkable increase in statistics obtainable at DAΦNE.
4 Radiative $K_{l3}$ decays

The decay channels considered in this subsection are

\[ K^+(p) \rightarrow \pi^0(p')l^+(p_l)\nu_l(p_\nu)\gamma(q) \quad [K^+_{l3\gamma}] \]
\[ K^0(p) \rightarrow \pi^-(p')l^+(p_l)\nu_l(p_\nu)\gamma(q) \quad [K^0_{l3\gamma}] \]

and the charge conjugate modes. We only consider real photons ($q^2 = 0$).

4.1 Matrix elements

The matrix element for $K^+_{l3\gamma}$ has the general structure

\[ T = \frac{G_F}{\sqrt{2}} e V^*_{us} \varepsilon^\mu(q) \left\{ (V^+_{\mu\nu} - A^+_{\mu\nu})\overline{\pi}(p_\nu)\gamma^\nu(1 - \gamma_5)v(p_l) \right\} + \frac{F^+_{\nu}}{2p_l q} \overline{\pi}(p_\nu)\gamma^\nu(1 - \gamma_5)(m_l - \not{p}_l - \not{q})\gamma_\mu v(p_l) \right\} \equiv \varepsilon^\mu A^+_{\mu}. \]

The diagram of Fig. 4.1.a corresponding to the first part of Eq. (4.1) includes Bremsstrahlung off the $K^+$. The lepton Bremsstrahlung diagram of Fig. 4.1.b is represented by the second part of Eq. (4.1). The hadronic tensors $V^+_{\mu\nu}, A^+_{\mu\nu}$ are defined as

\[ I^+_{\mu\nu} = i \int d^4x e^{iqx} \langle \pi^0(p') | T\{V_{\mu\nu}^{em}(x)I^{4-i5}_{\nu}(0) \} | K^+(p) \rangle, \quad I = V, A. \]

$F^+_{\nu}$ is the $K^+_{l3\gamma}$ matrix element

\[ F^+_{\nu} = \langle \pi^0(p') | V^{4-i5}_{\nu}(0) | K^+(p) \rangle. \]

The tensors $V^+_{\mu\nu}$ and $A^+_{\mu\nu}$ satisfy the Ward identities

\[ q^\mu V^+_{\mu\nu} = F^+_{\nu} \]
\[ q^\mu A^+_{\mu\nu} = 0 \]

leading in turn to

\[ q^\mu A^+_{\mu} = 0, \]

as is required by gauge invariance.

For $K^0_{l3\gamma}$, one obtains the corresponding amplitudes and hadronic tensors by making the replacements

\[ K^+ \rightarrow K^0, \quad \pi^0 \rightarrow \pi^- \]
\[ V^+_{\mu\nu} \rightarrow V^0_{\mu\nu}, \quad A^+_{\mu\nu} \rightarrow A^0_{\mu\nu} \]
\[ F^+_{\nu} \rightarrow F^0_{\nu}, \quad A^+_{\mu} \rightarrow A^0_{\mu}. \]
To make the infrared behaviour transparent, it is convenient to separate the tensors $V_{\mu\nu}^+, V_{\mu\nu}^0$ into two parts:

$$V_{\mu\nu}^+ = \hat{V}_{\mu\nu}^+ + \frac{p_\mu}{pq} F^+_{\nu}, \quad (4.7)$$

$$V_{\mu\nu}^0 = \hat{V}_{\mu\nu}^0 + \frac{p_\mu}{pq} F^0_{\nu}. \quad (4.8)$$

Due to Low’s theorem, the amplitudes $\hat{V}_{\mu\nu}^{+,0}$ are finite for $q \to 0$. The axial amplitudes $A_{\mu\nu}^{+,0}$ are automatically infrared finite. The Ward identity (4.4) implies that the vector amplitudes $\hat{V}_{\mu\nu}^{+,0}$ are transverse:

$$q^\mu \hat{V}_{\mu\nu}^{+,0} = 0. \quad (4.9)$$

For on-shell photons, Lorentz and parity invariance together with gauge invariance allow the general decomposition (dropping the superscripts $+,0$ and terms that vanish upon contraction with the photon polarization vector)

$$\hat{V}_{\mu\nu} = V_1 \left( g_{\mu\nu} - \frac{W_\mu q_\nu}{qW} \right) + V_2 \left( p'_\mu q_\nu - \frac{p'_\nu q}{qW} W_\mu q_\nu \right) + V_3 \left( p'_\mu W_\nu - \frac{p'_\nu q}{qW} W_\mu W_\nu \right) + V_4 \left( p'_\mu p'_\nu - \frac{p'_\nu q}{qW} W_\mu p'_\nu \right) \quad (4.9)$$

$$A_{\mu\nu} = i \varepsilon_{\mu\nu\rho\sigma} (A_1 p'^\rho q^\sigma + A_2 q^\rho W^\sigma) + i \varepsilon_{\mu\lambda\nu\rho} p^\lambda q^\rho W^\mu (A_3 W_\nu + A_4 p'_\nu)$$

$$F_{\nu} = C_1 p'_\nu + C_2 (p - p')_\nu$$

$$W = p_l + p_\nu.$$

With the decomposition (4.7) we can write the matrix element for $K_{l3}^{+\gamma}$ in (1.1) in a form analogous to Eq. (1.2) for $K_{l2}^{+\gamma}$:

$$T = \frac{G_F}{\sqrt{2}} e V_{us}^* \varepsilon^\mu(q)^* \left\{ (\hat{V}_{\mu\nu}^+ - A_{\mu\nu}^+) \overline{\mu}(p_\nu) \gamma^\nu (1 - \gamma_5) v(p_l) \right\}$$

$$+ F^+_{\nu} \overline{\nu}(p_\nu) \gamma^\nu (1 - \gamma_5) \left[ \frac{p_\mu}{pq} - \frac{(p_l + q - m_l)\gamma_\mu}{2p_l q} \right] v(p_l). \quad (4.10)$$

The four invariant vector amplitudes $V_1, \ldots, V_4$ and the four axial amplitudes $A_1, \ldots, A_4$ are functions of three scalar variables. A convenient choice for these variables is

$$E_\gamma = pq/M_K, \quad E_\pi = pp'/M_K, \quad W = \sqrt{W^2} \quad (4.11)$$

where $W$ is the invariant mass of the lepton pair. The amplitudes $C_1, C_2$ can be expressed in terms of the $K_{l3}$ form factors and depend only on the variable $(p - p')^2 = M_K^2 + M_\pi^2 - 2M_K E_\pi$. For the full kinematics of $K_{l3}\gamma$, two more variables are needed, e.g.

$$E_l = pp'/M_K, \quad x = p_l q/M_K^2. \quad (4.12)$$
The variable $x$ is related to the angle $\theta_{l\gamma}$ between the photon and the charged lepton in the $K$ rest frame:

$$xM_K^2 = E_\gamma (E_l - \sqrt{E_l^2 - m_l^2 \cos \theta_{l\gamma}}).$$

(4.13)

T invariance implies that the vector amplitudes $V_1, \ldots, V_4$, the axial amplitudes $A_1, \ldots, A_4$ and the $K_{l3}$ form factors $C_1, C_2$ are (separately) relatively real in the physical region. We choose the standard phase convention in which all amplitudes are real.

For $\theta_{l\gamma} \to 0$ (collinear lepton and photon), there is a lepton mass singularity in (4.1) which is numerically relevant for $l = e$. The region of small $E_\gamma, \theta_{l\gamma}$ is dominated by the $K_{l3}$ matrix elements. The new theoretical information of $K_{l3\gamma}$ decays resides in the tensor amplitudes $\hat{V}_{\mu\nu}$ and $A_{\mu\nu}$. The relative importance of these contributions can be enhanced by cutting away the region of low $E_\gamma, \theta_{l\gamma}$. It may turn out to be of advantage to reduce the statistics by applying more severe cuts than necessary from a purely experimental point of view.

### 4.2 Decay rates

The total decay rate is given by

$$\Gamma(K \to \pi l\nu\gamma) = \frac{1}{2M_K(2\pi)^8} \int d_{LIPS}(p, p', p_l, p_\nu, q) \sum_{\text{spins}} |T|^2$$

(4.14)

in terms of the amplitude $T$ in (4.1). The square of the matrix element, summed over photon and lepton polarizations, is a bilinear form in the invariant amplitudes.

---

Figure 4.1: Diagrammatic representation of the $K_{l3\gamma}^+$ amplitude.
V_1, \ldots, V_4, A_1, \ldots, A_4, C_1, C_2. Pulling out common factors, we write (4.14) in the form
\[ \Gamma(K \rightarrow \pi l \nu \gamma) = \frac{4 \alpha G_F^2 |V_{us}|^2}{(2\pi)^7 M_K} \int d_{LIPS}(p; p', p_l, p_\nu; q) \, SM \, , \] (4.15)
where SM is the reduced matrix element. For the actual numerical calculations, we have found it useful to employ a tensor decomposition different from the one in Eqs. (4.7) and (4.9)
\[ V_\mu \nu = B_1 g_{\mu \nu} + B_2 W_{\mu q} + B_3 p'_{\mu q} + B_4 W_{p'\nu} + B_5 W_{p' W_{\nu}} + B_6 p'_{\mu p'_{\nu}} + B_7 p'_{\mu p'_{\nu}} \, . \] (4.16)
One advantage is that (4.16) applies equally well to both charge modes while (4.7) does not. In the numerical evaluation of the amplitudes, gauge invariance can of course be used to express three of the \( B_i \) in terms of the remaining ones and of \( C_1, C_2 \).

To get some feeling for the magnitude of the various decay rates, let us first consider the tree level amplitudes to lowest order \( p^2 \) in CHPT. With the sign conventions of Ref. [44], these amplitudes are [11, 45]
\[ K^+_{\ell 3\gamma} : \]
\[ V^{+ \mu \nu} = \frac{1}{\sqrt{2}} \left[ g_{\mu \nu} + \frac{(p' + W)_\mu (2p' + W)_\nu}{pq} \right] \]
\[ A^{+ \mu \nu} = 0 \] (4.17)
\[ F^{+ \nu} = \frac{1}{\sqrt{2}} (p + p')_\nu \]
\[ K^0_{\ell 3\gamma} : \]
\[ V^{0 \mu \nu} = -g_{\mu \nu} + \frac{p'_{\mu} (2p' + 2q + W)_\nu}{p' q} \]
\[ A^{0 \mu \nu} = 0 \] (4.18)
\[ F^{0 \nu} = (p + p')_\nu. \]

In table 4.1 the corresponding branching ratios are presented for the four decay modes for \( E_\gamma \geq 30MeV \) and \( \theta_{l\gamma} \geq 20^\circ \). For \( K^0_{\ell 3\gamma} \), the rates are to be understood as \( \Gamma(K_L \rightarrow \pi^\pm l^\mp \nu \gamma) \). The number of events correspond to the design values for DAΦNE (cf. App. A).
Table 4.1: Branching ratios for tree level amplitudes for $E_\gamma \geq 30\text{MeV}$ and $\theta_{l\gamma} \geq 20^\circ$ in the $K$ rest frame.

| decay | BR(tree) | # events/yr |
|-------|----------|-------------|
| $K^+_e\gamma$ | $2.8 \times 10^{-4}$ | $2.5 \times 10^6$ |
| $K^+_{\mu3\gamma}$ | $1.9 \times 10^{-5}$ | $1.7 \times 10^5$ |
| $K^0_{e3\gamma}$ | $3.6 \times 10^{-3}$ | $4.0 \times 10^6$ |
| $K^0_{\mu3\gamma}$ | $5.2 \times 10^{-4}$ | $5.7 \times 10^6$ |

Table 4.2: Experimental results for $K_{l3\gamma}$ decays

| decay | exp. | $E_{\gamma,\text{min}}$ | # events | BR |
|-------|------|-------------------------|----------|----|
| $K^+_{e3\gamma}$ | 10 | 10 MeV | 192 | $(2.7 \pm 0.2) \times 10^{-4}$ |
| $K^+_{\mu3\gamma}$ | 17 | 10 MeV | 13 | $(3.7 \pm 1.3) \times 10^{-4}$ |
| $K^0_{e3\gamma}$ | 18 | 30 MeV | 16 | $(2.3 \pm 1.0) \times 10^{-4}$ |
| $K^0_{\mu3\gamma}$ | 18 | 30 MeV | 0 | $< 6.1 \times 10^{-5}$ |
| $K^0_\gamma$ | 19 | 15 MeV | 10 | $(1.3 \pm 0.8) \times 10^{-2}$ |

4.3 Previous experiments

The data sample for $K_{l3\gamma}$ decays is very limited and it is obvious that DAΦNE will be able to make significant improvements. The present experimental status is summarized in table 4.2.

A comparison between tables 4.1 and 4.2 shows the tremendous improvement in statistics to be expected at DAΦNE. We shall come back to the question whether this improvement will be sufficient to test the standard model at the next-to-leading order, $O(p^4)$, in CHPT.

4.4 Theory

Prior to CHPT, the most detailed calculations of $K_{l3\gamma}$ amplitudes were performed by Fearing, Fischbach and Smith [50] using current algebra techniques.

In the framework of CHPT, the amplitudes are given by (4.17) and (4.18) to leading order in the chiral expansion.

4.4.1 CHPT to $O(p^4)$

There are in general three types of contributions [44]: anomaly, local contributions due to $L_4$ and loop amplitudes.
Figure 4.2: Loop diagrams (without tadpoles) for $K_l^3$ at $O(p^4)$. For $K_{l3\gamma}$, the photon must be appended on all charged lines and on all vertices.

The anomaly contributes to the axial amplitudes

$$A^+_{\mu\nu} = \frac{i\sqrt{2}}{16\pi^2 F^2} \left\{ \varepsilon_{\mu\rho\sigma} p'(4p' + W)^\sigma + \frac{4}{W^2 - M_K^2} \varepsilon_{\mu\lambda\rho\sigma} W_\nu P^\lambda q^\rho W^\sigma \right\} \quad (4.19)$$

$$A^0_{\mu\nu} = -\frac{i}{8\pi^2 F^2} \varepsilon_{\mu\rho\sigma} q^\rho W^\sigma.$$

The loop diagrams for $K_{l3\gamma}$ are shown in Fig. 4.2. We first write the $K_{l3}^+$ matrix element in terms of three functions $f^+_1, f^+_2, f^+_3$ which will also appear in the invariant amplitudes $V^+_i$. Including the contributions from the low-energy constants $L_5, L_9$ in $\mathcal{L}_4$, the $K_{l3}$ matrix element $F^+_\nu$ is given by

$$F^+_\nu = f^+_1(t_p) p'_\nu + \left[ \frac{1}{2}(M_K^2 - M_\pi^2 - t) f^+_2(t) + f^+_3(t) \right] (p - p')_\nu$$

$$f^+_1(t) = \frac{\sqrt{2} + 4L_9}{\sqrt{2} F^2} t + 2 \sum_{l=1}^{3} (c^l_1 - c^l_2) B^l_2(t)$$

$$f^+_2(t) = -\frac{4L_9}{\sqrt{2} F^2} + \frac{1}{2t} \sum_{l=1}^{3} \left\{ (c^l_1 - c^l_2) \left[ 2B^l_2(t) - \frac{(t + \Delta I)\Delta I J_1(t)}{2t} \right] - c^l_2 \Delta I J_1(t) \right\}$$

$$f^+_3(t) = \frac{F_K}{\sqrt{2} F_\pi} + \frac{1}{2t} \sum_{l=1}^{3} \left\{ (c^l_1 + c^l_2)(t + \Delta I) - 2c^l_3 \right\} \Delta I J_1(t) \quad (4.20)$$

$$L_9 = L_9(\mu) - \frac{1}{256\pi^2} \ln \frac{M_\pi M_K^2 M_\eta}{\mu^4}$$

$$\Delta I = M^2_I - m^2_I, \quad t = (p - p')^2.$$
Table 4.3: Coefficients for the $K_{l3\gamma}^+$ loop amplitudes corresponding to the diagrams $I = 1, 2, 3$ in Fig. 4.2. All coefficients $c_i^I$ must be divided by $6\sqrt{2}F^2$.

| $I$ | $M_I$ | $m_I$ | $c_1^I$ | $c_2^I$ | $c_3^I$ |
|-----|-------|-------|---------|---------|---------|
| 1   | $M_K$ | $M_\pi$ | 1       | -2      | $-M_K^2 - 2M_\pi^2$ |
| 2   | $M_K$ | $M_\eta$ | 3       | -6      | $-M_K^2 - 2M_\eta^2$ |
| 3   | $M_\pi$ | $M_K$ | 0       | -6      | $-6M_\pi^2$ |

$L_9$ is a scale independent coupling constant and we have traded the tadpole contribution together with $L_5$ for $F_K/F_\pi$ in $f_3^+(t)$. The sum over $I$ corresponds to the three loop diagrams of Fig. 4.2 with coefficients $c_1^I, c_2^I, c_3^I$ displayed in table 4.3. We use the Gell-Mann–Okubo mass formula throughout to express $M_\eta^2$ in terms of $M_K^2, M_\pi^2$. The functions $J_I(t)$ and $B_I^2(t)$ can be found in App. B.

The standard $K_{l3}$ form factors $f_+(t), f_-(t)$ as given in the previous subsection [24] are

$$f_+(t) = \frac{1}{\sqrt{2}} f_1^+(t)$$
$$f_-(t) = \frac{1}{\sqrt{2}} \left[ (M_K^2 - M_\pi^2 - t) f_2^+(t) + 2f_3^+(t) - f_1^+(t) \right]. \tag{4.21}$$

It remains to calculate the infrared finite tensor amplitude $\hat{V}_{\mu\nu}$. The invariant amplitudes $V_i^+$ can be expressed in terms of the previously defined functions $f_i^+$ and of additional amplitudes $I_1, I_2, I_3$. Diagrammatically, the latter amplitudes arise from those diagrams in Fig. 4.2 where the photon is not appended on the incoming $K^+$ (non-Bremsstrahlung diagrams). The final expressions are

$$V_1^+ = I_1 + p'W_q f_2^+ (W_q^2) + f_3^+ (W_q^2)$$
$$V_2^+ = I_2 - \frac{1}{pq} \left[ p'W_q f_2^+ (W_q^2) + f_3^+ (W_q^2) \right]$$
$$V_3^+ = I_3 + \frac{1}{pq} \left[ p'W f_2^+ (W^2) + f_3^+ (W^2) - p'W_q f_2^+ (W_q^2) - f_3^+ (W_q^2) \right] \tag{4.22}$$
$$V_4^+ = \frac{f_1^+ (W^2) - f_1^+ (W_q^2)}{pq}$$
$$W_q = W + q = p - p'. \tag{39}$$
The amplitudes $I_1, I_2, I_3$ in Eq. (4.22) are given by

$$I_1 = \frac{4qW}{\sqrt{2}F^2} (L_9 + L_{10}) + \frac{8p'q}{\sqrt{2}F^2} L_9$$

$$+ \sum_{i=1}^{3} \left\{ \left[ (W_q^2 + \Delta_I)(c_i^1 + c_i^2) - 2(c_i^2 p' W_q + c_i^3) \right] \left[ \frac{(W_q^2 - \Delta_I)J_i}{2W_q^2} - 2G_I \right] \right.$$  

$$+ \left[ \frac{p'W_q(W_q^4 - \Delta_q^2)J_i}{W_q^2} + 4\hat{B}_i^2 \right] + p'(W - q)L_m^I \right\}$$

$$+ \frac{2(c_i^1 - c_i^2)}{qW} \left[ p'q(F_i - (W_q^2 + \Delta_I)G_I) + p'W(\hat{B}_2^I - B_2^I) \right] \}$$

$$I_2 = -\frac{8L_9}{\sqrt{2}F^2} + \frac{2}{qW} \sum_{i=1}^{3} (c_i^1 - c_i^2) \left[ F_i - (W^2 + \Delta_I)G_I \right]$$

$$I_3 = -\frac{4L_9}{\sqrt{2}F^2} + \sum_{i=1}^{3} \left\{ 2(c_i^1 - c_i^2) \left[ G_I + \frac{L_m^I}{4} + \frac{\hat{B}_i^2 - B_2^I}{qW} \right] - c_i^1 \frac{\Delta_I J_i}{W^2} \right\} \} \quad (4.23)$$

$$\overline{L_{10}} = L_{10}(\mu) + \frac{1}{256\pi^2} \ln \frac{M_\pi M_K M_\eta}{\mu^4}$$

$$L_m^I = \frac{\Sigma_I}{32\pi^2 \Delta_I} \ln \frac{m_i^2}{M_i^2}$$

$$F_I = \hat{B}_2^I - \frac{W^2}{4}L_m^I + \frac{1}{qW} \left( W^2 B_2^I - W_q^2 \hat{B}_2^I \right)$$

$$G_I = M_i^2 C(W_q^2, W^2, M_i^2, m_i^2) + \frac{1}{8qW} \left[ (W_q^2 + \Delta_I)J_i - (W^2 + \Delta_I)J_i \right]$$

$$J_I \equiv J_i(W_q^2), \quad \hat{J}_I \equiv J_i(W^2)$$

$$B_2^I \equiv B_2^I(W_q^2), \quad \hat{B}_2^I \equiv B_2^I(W_q^2).$$

The function $C(W_q^2, W^2, M_i^2, m_i^2)$ is given in App. [3]. All the invariant amplitudes $V_1^+, \ldots, V_4^+$ are real in the physical region. Of course, the same is true for the $K_{3\gamma}$ matrix element $V_{\nu}^+.$

The $K_{3\gamma}$ amplitude has a very similar structure. Both the $K_{3\gamma}$ matrix element $F_{\nu}^0$ and the infrared finite vector amplitude $\hat{V}_{\mu \nu}^0$ can be obtained from the corresponding quantities $F_{\nu}^+$ and $\hat{V}_{\mu \nu}^+$ by the following steps:

- interchange $p'$ and $-p$;
- replace $\frac{F_K}{F_\pi}$ by $\frac{F_\pi}{F_K}$ in $f_3^+$;
- insert the appropriate coefficients $c_i^j$ for $K_{3\gamma}^0$ listed in table [4,5];
- multiply $F_{\nu}^+$ and $\hat{V}_{\mu \nu}^+$ by a factor $-\sqrt{2}.$
Table 4.4: Coefficients for the $K^0_{l3\gamma}$ loop amplitudes corresponding to the diagrams $I = 1, 2, 3$ in Fig. [4.2]. All coefficients $c^I_i$ must be divided by $6\sqrt{2}F^2$.

| $I$ | $M_I$ | $m_I$ | $c^I_1$ | $c^I_2$ | $c^I_3$ |
|-----|------|------|--------|--------|--------|
| 1   | $M_K$ | $M_\pi$ | 0      | -3     | $-3M_K^2$ |
| 2   | $M_K$ | $M_\eta$ | 6      | -3     | $M_K^2 + 2M_\pi^2$ |
| 3   | $M_\pi$ | $M_K$ | 4      | -2     | $-2M_K^2 + 2M_\pi^2$ |

Table 4.5: Branching ratios and expected number of events at DAΦNE for $K^+_{l3\gamma}$.

| $K^+_{e3\gamma}$ | BR     | #events/yr |
|------------------|--------|------------|
| full $O(p^4)$ amplitude | $3.0 \times 10^{-4}$ | $2.7 \times 10^6$ |
| tree level        | $2.8 \times 10^{-4}$ | $2.5 \times 10^6$ |
| $O(p^4)$ without loops | $3.2 \times 10^{-4}$ | $2.9 \times 10^6$ |

| $K^+_{\mu3\gamma}$ | BR     | #events/yr |
|---------------------|--------|------------|
| full $O(p^4)$ amplitude | $2.0 \times 10^{-5}$ | $1.8 \times 10^5$ |
| tree level          | $1.9 \times 10^{-5}$ | $1.7 \times 10^5$ |
| $O(p^4)$ without loops | $2.1 \times 10^{-5}$ | $1.9 \times 10^5$ |

4.4.2 Numerical results

In calculating the rates with the complete amplitudes of the previous subsection, we use the same cuts as for the tree level rates in Subsect. [4.2]:

\[ E_\gamma \geq 30 \text{MeV} \quad (4.24) \]
\[ \theta_{l\gamma} \geq 20^\circ. \]

The physical values of $M_\pi$ and $M_K$ are used in the amplitudes. $M_\eta$ is calculated from the Gell-Mann–Okubo mass formula. The values of the other parameters can be found in Ref. [3] and in appendix [A].

The results for $K^+_{e3\gamma}$ and $K^0_{l3\gamma}$ are displayed in tables [4.5] and [4.6], respectively. For comparison, the tree level branching ratios of table [4.1] and the rates for the amplitudes without the loop contributions are also shown. The separation between loop and counterterm contributions is of course scale dependent. This scale dependence is absorbed in the scale invariant constants $L_9, L_{10}$ defined in Eqs. (4.20), (4.23). In other words, the entries in tables [4.5] for the amplitudes without loops correspond to setting all coefficients $c^I_i$ in tables [4.3], [4.4] equal to zero.
Table 4.6: Branching ratios and expected number of events at DAΦNE for \(K_0^{0}\) or \(K_0^{0}\).

| \(K_{e3\gamma}^0\) | BR         | #events/yr |
|-------------------|------------|------------|
| full \(O(p^4)\) amplitude | \(3.8 \times 10^{-3}\) | \(4.2 \times 10^6\) |
| tree level        | \(3.6 \times 10^{-3}\) | \(4.0 \times 10^6\) |
| \(O(p^4)\) without loops | \(4.0 \times 10^{-3}\) | \(4.4 \times 10^6\) |

| \(K_{\mu3\gamma}^0\) | BR         | #events/yr |
|-----------------------|------------|------------|
| full \(O(p^4)\) amplitude | \(5.6 \times 10^{-4}\) | \(6.1 \times 10^9\) |
| tree level            | \(5.2 \times 10^{-4}\) | \(5.7 \times 10^5\) |
| \(O(p^4)\) without loops | \(5.9 \times 10^{-4}\) | \(6.5 \times 10^5\) |

4.5 Improvements at DAΦNE

The numerical results given above demonstrate very clearly that the non-trivial CHPT effects of \(O(p^4)\) can be detected at DAΦNE in all four channels without any problem of statistics. Of course, the rates are bigger for the electronic modes. On the other hand, the relative size of the structure dependent terms is somewhat bigger in the muonic channels (around 8% for the chosen cuts). We observe that there is negative interference between the loop and counterterm amplitudes.

The sensitivity to the counterterm coupling constants \(L_9\), \(L_{10}\) and to the chiral anomaly can be expressed as the difference in the number of events between the tree level and the \(O(p^4)\) amplitudes (without loops). In the optimal case of \(K_{e3\gamma}^0\), this amounts to more than \(4 \times 10^5\) events/yr at DAΦNE. Almost all of this difference is due to \(L_9\). It will be very difficult to extract the coupling constant \(L_{10}\) from the total rates. A more detailed study is needed to determine whether \(L_{10}\) can be extracted from differential distributions.

The chiral anomaly is more important for \(K_{e3\gamma}^0\), but even there it influences the total rates rather little. Once again, a dedicated study of differential rates is necessary to locate the chiral anomaly, if possible at all.

On the other hand, taking into account that \(L_9\) is already known to good accuracy (see table 1 in Ref. [2]), \(K_{e3\gamma}^0\) decays will certainly allow for precise and unambiguous tests of the one-loop effects in CHPT [1].
5 $K_{l4}$ decays

In this subsection we discuss the decays

\[ \begin{align*}
K^+(p) & \rightarrow \pi^+(p_1) \pi^-(p_2) l^+(p_l) \nu_l(p_\nu) & (5.1) \\
K^+(p) & \rightarrow \pi^0(p_1) \pi^0(p_2) l^+(p_l) \nu_l(p_\nu) & (5.2) \\
K^0(p) & \rightarrow \pi^0(p_1) \pi^- (p_2) l^+(p_l) \nu_l(p_\nu) & (5.3)
\end{align*} \]

and their charge conjugate modes. The letter $l$ stands for $e$ or $\mu$. We do not consider isospin violating contributions and correspondingly set $m_u = m_d$, $\alpha = 0$.

5.1 Kinematics

We start with the process (5.1). The full kinematics of this decay requires five variables. We will use the ones introduced by Cabibbo and Maksymowicz [51]. It is convenient to consider three reference frames, namely the $K^+$ rest system ($\Sigma_K$), the $\pi^+\pi^-$ center-of-mass system ($\Sigma_{2\pi}$) and the $l^+\nu_l$ center-of-mass system ($\Sigma_{l\nu}$). Then the variables are

1. $s_\pi$, the effective mass squared of the dipion system,
2. $s_l$, the effective mass squared of the dilepton system,
3. $\theta_\pi$, the angle of the $\pi^+$ in $\Sigma_{2\pi}$ with respect to the dipion line of flight in $\Sigma_K$,
4. $\theta_l$, the angle of the $l^+$ in $\Sigma_{l\nu}$ with respect to the dilepton line of flight in $\Sigma_K$,
5. $\phi$, the angle between the plane formed by the pions in $\Sigma_K$ and the corresponding plane formed by the dileptons.

The angles $\theta_\pi$, $\theta_l$ and $\phi$ are displayed in Fig. [5.1]. In order to specify these variables more precisely, let $\vec{p}_1$ be the three-momentum of the $\pi^+$ in $\Sigma_{2\pi}$ and $\vec{p}_l$ the three-momentum of the $l^+$ in $\Sigma_{l\nu}$. Furthermore, let $\vec{v}$ be a unit vector along the direction of flight of the dipion in $\Sigma_K$, and $\vec{c}(\vec{d})$ a unit vector along the projection of $\vec{p}_l(\vec{p}_\nu)$ perpendicular to $\vec{v}(-\vec{v})$,

\[ \begin{align*}
\vec{c} &= (\vec{p}_1 - \vec{v} \vec{v} \cdot \vec{p}_1)/(|\vec{p}_1|^2 - (\vec{p}_1 \cdot \vec{v})^2)^{1/2} \\
\vec{d} &= (\vec{p}_l - \vec{v} \vec{v} \cdot \vec{p}_l)/(|\vec{p}_l|^2 - (\vec{p}_l \cdot \vec{v})^2)^{1/2}.
\end{align*} \]

The vectors $\vec{v}$, $\vec{c}$ and $\vec{d}$ are indicated in Fig. [5.1]. Then, one has

\[ \begin{align*}
s_\pi &= (p_1 + p_2)^2, & s_l &= (p_l + p_\nu)^2 \\
\cos \theta_\pi &= \vec{v} \cdot \vec{p}_1/|\vec{p}_1|, & \cos \theta_l &= -\vec{v} \cdot \vec{p}_l/|\vec{p}_l| \\
\cos \phi &= \vec{c} \cdot \vec{d}, & \sin \phi &= (\vec{c} \times \vec{v}) \cdot \vec{d}.
\end{align*} \]
Figure 5.1: Kinematic variables for $K_{l4}$ decays. The angle $\theta_\pi$ is defined in $\Sigma_{2\pi}, \theta_l$ in $\Sigma_{l\nu}$ and $\phi$ in $\Sigma_K$.

The range of the variables is

$$
4M_\pi^2 \leq s_\pi \leq (M_K - m_l)^2
$$
$$
m_l^2 \leq s_l \leq (M_K - \sqrt{s_\pi})^2
$$
$$
0 \leq \theta_\pi, \theta_l \leq \pi, 0 \leq \phi \leq 2\pi.
$$

(5.5)

It is useful to furthermore introduce the following combinations of four vectors

$$
P = p_1 + p_2, \quad Q = p_1 - p_2, \quad L = p_l + p_\nu, \quad N = p_l - p_\nu
$$

(5.6)

together with the corresponding Lorentz invariant scalar products

$$
P^2 = s_\pi, \quad Q^2 = 4M_\pi^2 - s_\pi, \quad L^2 = s_l, \quad N^2 = 2m_l^2 - s_l,
$$
$$
PQ = 0,
$$
$$
PL = \frac{1}{2}(M_K^2 - s_\pi - s_l),
$$
$$
PN = z_l PL + (1 - z_l) X \cos \theta_l,
$$
$$
QL = \sigma_\pi X \cos \theta_\pi,
$$
$$
QN = z_l QL + \sigma_\pi (1 - z_l) [PL \cos \theta_\pi \cos \theta_l
$$
$$
- (s_\pi s_l)^{1/2} \sin \theta_\pi \sin \theta_l \cos \phi]
$$
$$
LN = m_l^2
$$

$$
< LNPQ > \equiv \epsilon_{\mu\nu\rho\sigma} L^\mu N^\nu P^\rho Q^\sigma
$$
$$
= -(s_\pi s_l)^{1/2} \sigma_\pi (1 - z_l) X \sin \theta_\pi \sin \theta_l \sin \phi
$$

(5.7)

with

$$
X = ((PL)^2 - s_\pi s_l)^{1/2} = \frac{1}{2} \lambda^{1/2} (M_K^2, s_\pi, s_l)
$$
$$
z_l = m_l^2 / s_l
$$
$$
\sigma_\pi = (1 - 4M_\pi^2 / s_\pi)^{1/2}.
$$

(5.8)
Below we will also use the variables
\[
    t = (p_1 - p)^2, \\
    u = (p_2 - p)^2.
\]  
These are related to \(s_\pi, s_l\) and \(\theta_\pi\) by
\[
    t + u = 2M_\pi^2 + M_K^2 + s_l - s_\pi \\
    t - u = -2\sigma_\pi X \cos \theta_\pi.
\]  

5.2 Matrix elements

The matrix element for \(K^+ \to \pi^+\pi^- l^+ \nu_l\) is
\[
    T = \frac{G_F}{\sqrt{2}} V^*_{us} \bar{u}(p_\nu) \gamma_\mu (1 - \gamma_5) v(p_l)(V^\mu - A^\mu)
\]  
where
\[
    I_\mu = < \pi^+(p_1)\pi^-(p_2)\text{out} \mid I^{4-i5}(0) \mid K^+(p)>; \quad I = V,A \\
    V_\mu = -\frac{H}{M_K^2} \epsilon_{\mu\rho\sigma\tau} L^\rho P^\sigma Q^\tau \\
    A_\mu = -i \frac{1}{M_K} [P_\mu F + Q_\mu G + L_\mu R]
\]  
and \(\epsilon_{0123} = 1\). The matrix elements for the other channels \((5.2, 5.3)\) may be obtained from \((5.11, 5.12)\) by isospin symmetry, see below.

The form factors \(F, G, R\) and \(H\) are real analytic functions of the three variables \(p_1p_2, p_1p\) and \(p_2p\). Below, we will use instead the variables \(\{s_\pi, s_l, \theta_\pi\}\) or \(\{s_\pi, t, u\}\).

Remark: In order to agree with the notation used by Pais and Treiman \([52]\) and by Rosselet et al. \([53]\), we have changed our previous convention \([54, 55]\) in the definition of the anomaly form factor \(H\). See also the comments after Eq. \((5.21)\).

5.3 Decay rates

The partial decay rate for \((5.1)\) is given by
\[
    d\Gamma = \frac{1}{2M_K(2\pi)^8} \sum_{\text{spins}} |T|^2 d_{LIPS}(p; p_1, p_\nu, p_1, p_2).
\]  
The quantity \(\sum_{\text{spins}} |T|^2\) is a Lorentz invariant quadratic form in \(F, G, R\) and \(H\). All scalar products can be expressed in the 5 independent variables \(s_\pi, s_l, \theta_\pi, \theta_l\) and \(\phi\), such that
\[
    \sum_{\text{spins}} |T|^2 = 2G_F^2 |V_{us}|^2 M_K^2 J_5(s_\pi, s_l, \theta_\pi, \theta_l, \phi).
\]  

45
Carrying out the integrations over the remaining $4 \cdot 3 - 5 = 7$ variables in (5.13) gives

$$d\Gamma_5 = G^2_F |V_{us}|^2 N(s_{\pi}, s_{l}) J_5(s_{\pi}, s_{l}, \theta_{\pi}, \theta_{l}, \phi) ds_{\pi} ds_{l} d(\cos \theta_{\pi}) d(\cos \theta_{l}) d\phi$$

(5.15)

where

$$N(s_{\pi}, s_{l}) = (1 - z_{l})\sigma_{\pi} X / (213\pi^6 M_K^5) .$$

(5.16)

The form factors $F, G, R$ and $H$ are independent of $\phi$ and $\theta_{l}$. It is therefore possible to carry out two more integrations in (5.15) with the result

$$d\Gamma_3 = G^2_F |V_{us}|^2 N(s_{\pi}, s_{l}) J_3(s_{\pi}, s_{l}, \theta_{\pi}) ds_{\pi} ds_{l} d(\cos \theta_{\pi}).$$

(5.17)

The explicit form of $J_5$ is

$$J_5 = |F|^2 [(PL)^2 - (PN)^2 - s_{\pi} s_{l} + m_{l}^2 s_{\pi}]$$

$$+ |G|^2 [(QL)^2 - (QN)^2 - Q^2 s_{l} + m_{l}^2 Q^2]$$

$$+ |R|^2 m_{l}^2 [s_{l} - m_{l}^2]$$

$$+ \frac{1}{M_K^2} |H|^2 [(m_{l}^2 - s_{l}) (Q^2 X^2 + s_{\pi}(QL)^2] - < LNPQ >^2$$

$$+ (F^*G + FG^*) [(PL)(QL) - (PN)(QN)]$$

$$+ (F^*R + FR^*) (s_{l} - m_{l}^2) [(PL) - (PN)]$$

$$+ \frac{1}{M_K^2} (F^*H + FH^*) [(QN)(PL)^2 - (QL)(PL)(PN) - s_{\pi} s_{l}(QN) + m_{l}^2 s_{\pi}(QL)]$$

$$+ (G^*R + GR^*) (s_{l} - m_{l}^2) [(QL) - (QN)]$$

$$+ \frac{1}{M_K^2} (G^*H + GH^*) [(PL)(QL)(QN) - (PN)(QL)^2 + s_{l}(PN)Q^2 - m_{l}^2 (PL)Q^2]$$

$$+ \frac{i}{M_K^2} < LNPQ > [[F^*G - FG^*]M_K^2 + (F^*H - FH^*)(PN)]$$

$$+ (G^*H - GH^*)(QN) + (R^*H - RH^*)m_{l}^2$$

(5.18)

For data analysis it is useful to represent this result in a still different form which displays the $\theta_{l}$ and $\phi$ dependence more clearly [52]:

$$J_5 = 2(1 - z_{l}) \left[ I_1 + I_2 \cos 2\theta_{l} + I_3 \sin^2 \theta_{l} \cdot \cos 2\phi + I_4 \sin 2\theta_{l} \cdot \cos \phi + I_5 \sin \theta_{l} \cdot \cos \phi + I_6 \cos \theta_{l} + I_7 \sin \theta_{l} \cdot \sin \phi + I_8 \sin 2\theta_{l} \cdot \sin \phi + I_9 \sin^2 \theta_{l} \cdot \sin 2\phi \right].$$

(5.19)

One obtains

$$I_1 = \frac{1}{4} \left\{ (1 + z_{l})|F_1|^2 + \frac{1}{2}(3 + z_{l}) \left( |F_2|^2 + |F_3|^2 \right) \sin^2 \theta_{\pi} + 2z_{l}|F_4|^2 \right\}$$
\[ I_2 = -\frac{1}{4}(1 - z_l) \left\{ |F_1|^2 - \frac{1}{2} \left( |F_2|^2 + |F_3|^2 \right) \sin^2 \theta_\pi \right\} \]
\[ I_3 = -\frac{1}{4}(1 - z_l) \left\{ |F_2|^2 - |F_3|^2 \right\} \sin^2 \theta_\pi \]
\[ I_4 = \frac{1}{2}(1 - z_l) \Re(F_1^* F_2) \sin \theta_\pi \]
\[ I_5 = - \left\{ \Re(F_1^* F_3) + z_l \Re(F_4^* F_2) \right\} \sin \theta_\pi \]
\[ I_6 = - \left\{ \Re(F_2^* F_3) \sin^2 \theta_\pi - z_l \Re(F_1^* F_4) \right\} \]
\[ I_7 = - \left\{ \Im(F_1^* F_2) + z_l \Im(F_4^* F_3) \right\} \sin \theta_\pi \]
\[ I_8 = \frac{1}{2}(1 - z_l) \Im(F_1^* F_3) \sin \theta_\pi \]
\[ I_9 = -\frac{1}{2}(1 - z_l) \Im(F_2^* F_3) \sin^2 \theta_\pi , \]

where

\[ F_1 = X \cdot F + \sigma_\pi (PL) \cos \theta_\pi \cdot G \]
\[ F_2 = \sigma_\pi (s_\pi s_l)^{1/2} G \]
\[ F_3 = \sigma_\pi X (s_\pi s_l)^{1/2} \frac{H}{M_K^2} \]
\[ F_4 = -(PL)F - s_l R - \sigma_\pi X \cos \theta_\pi \cdot G . \]

The definition of \( F_1, \ldots, F_4 \) in (5.21) corresponds to the combinations used by Pais and Treiman [52] (the different sign in the terms \( \sim PL \) is due to our use of the metric diag\((+ - - -)\)). The form factors \( I_1, \ldots, I_9 \) agree with the expressions given in [52]. We conclude that our convention for the relative phase in the definition of the form factors in Eq. (5.12) agrees with the one used by Pais and Treiman. The comparison of (5.18) with [53, table II] shows furthermore that it also agrees with this reference.

The quantity \( J_3 \) can now easily be obtained from (5.19) by integrating over \( \phi \) and \( \theta_2 \),

\[ J_3 = \int d\phi \, d(\cos \theta_2) J_5 = 8\pi (1 - z_l) \left[ I_1 - \frac{1}{3} I_2 \right]. \]

\[ \text{(5.22)} \]

### 5.4 Isospin decomposition

The \( K_{l4} \) decays (5.2) and (5.3) involve the same form factors as displayed in Eq. (5.12). We denote by \( A_{+-}, A_{00} \) and \( A_0 \) the current matrix elements of the processes (5.1)-(5.3). These are related by isospin symmetry [47],

\[ A_{+-} = \frac{A_0}{\sqrt{2}} - A_{00} . \]

\[ \text{(5.23)} \]

\(^5\)We use the Condon-Shortley phase conventions.
This relation also holds for the individual form factors, which may be decomposed into a symmetric and an antisymmetric part under $t \leftrightarrow u$ ($p_1 \leftrightarrow p_2$). Because of Bose symmetry and of the $\Delta I = \frac{1}{2}$ rule of the relevant weak currents, one has

$$
(F, G, R, H)_{00} = -(F^+, G^-, R^+, H^-)_{+-}
$$

$$(F, G, R, H)_{0-} = \sqrt{2}(F^-, G^+, R^-, H^+)_{+-}
$$

where

$$
F^\pm_{+-} = \frac{1}{2}[F(s_\pi, t, u) \pm F(s_\pi, u, t)]
$$

and $F(s_\pi, t, u)$ is defined in Eq. (5.12).

The isospin relation for the decay rates is

$$
\Gamma(K^+ \to \pi^+\pi^-l^+\nu_l) = \frac{1}{2}\Gamma(K_L \to \pi^0\pi^+l^\mp\nu) + 2\Gamma(K^+ \to \pi^0\pi^0l^+\nu_l)
$$

Isospin violating contributions affect the matrix elements and phase space, as a result of which this relation is modified. In order to illustrate the (substantial) effects from asymmetries in phase space, we take constant form factors $F, G$ and set $R = 0, H = 0$. Eq. (5.26) then reads (with physical masses for $K^+ \to \pi^+\pi^-l^+\nu_l, \pi^0\pi^0l^+\nu_l$ and with $M_{\pi^0} = M_{\pi^\pm} = 137$ MeV in $K_L \to \pi^0\pi^+l^\pm\nu$)

$$
(16.0F^2 + 3.1G^2)\Gamma_0 = (20.1F^2 + 2.0G^2)\Gamma_0
$$

$$
\Gamma_0 = V_{us}^2 \cdot 10^2 \text{sec}^{-1}
$$

in the electron mode and

$$
(1.79F^2 + 0.25G^2)\Gamma_0 = (2.64F^2 + 0.20G^2)\Gamma_0
$$

in the muon mode.

### 5.5 Partial wave expansion

The form factors may be written in a partial wave expansion in the variable $\theta_\pi$. We consider a definite isospin $\pi\pi$ state. Suppressing isospin indices, one has

$$
F = \sum_{l=0}^{\infty} P_l(\cos \theta_\pi) f_l - \frac{\sigma_{\pi} P L}{X} \cos \theta_\pi G
$$

$$
G = \sum_{l=1}^{\infty} P'_l(\cos \theta_\pi) g_l
$$

$$
R = \sum_{l=0}^{\infty} P_l(\cos \theta_\pi) r_l + \frac{\sigma_{\pi} s_{\pi}}{X} \cos \theta_\pi G
$$

$$
H = \sum_{l=0}^{\infty} P'_l(\cos \theta_\pi) h_l
$$

(5.29)
Table 5.1: Rates of $K_{l4}$ decays [3]. The data for $K_L \to \pi^0 \pi^\pm e^\mp \nu$ is from ref. [60].

| Decay                  | # events | Particle Data Group | DAΦNE 1 yr | Improvement |
|------------------------|----------|---------------------|------------|-------------|
| $K^+ \to \pi^+ \pi^- e^+ \nu_e$ | $3.91 \cdot 10^{-5}$ | $3 \cdot 10^4$ | $3 \cdot 10^5$ | 10          |
| $K^+ \to \pi^0 \pi^0 e^+ \nu_e$ | $2.1 \cdot 10^{-5}$ | $< 50$ | $2 \cdot 10^5$ | $> 4 \cdot 10^3$ |
| $K_L \to \pi^0 \pi^\pm e^\mp \nu$ | $5.16 \cdot 10^{-5}$ | 729 | $7 \cdot 10^4$ | $7 \cdot 10^2$ |
| $K^+ \to \pi^+ \pi^- \mu^+ \nu_\mu$ | $10^{-6}$ | 7 | $2 \cdot 10^4$ | $3 \cdot 10^3$ |

where

$$P'_l(z) = \frac{d}{dz} P_l(z) \, . \quad (5.30)$$

The partial wave amplitudes $f_l, g_l, r_l, h_l$ depend on $s_\pi$ and $s_l$. Their phase coincides with the phase shifts $\delta^I_l$ in elastic $\pi\pi$ scattering (angular momentum $l$, isospin $I$). More precisely, the quantities

$$e^{-i\delta^0_l} X_{2l} \quad e^{-i\delta^I_l} X_{2l+1} ; \ l = 0, 1, \ldots \ ; X = f, g, r, h$$

are real in the physical region of $K_{l4}$ decay. The form factors $F_1$ and $F_4$ therefore have a simple expansion

$$F_1 = X \sum_l P_l(\cos \theta_\pi) f_l$$

$$F_4 = - \sum_l P_l(\cos \theta_\pi)(PLf_l + s_l r_l). \quad (5.32)$$

On the other hand, the phase of the projected amplitudes

$$F_{2l} = \int P_l(\cos \theta_\pi) F_{2l} d(\cos \theta_\pi) ; \ l = 0, 1, 2, \ldots \quad (5.33)$$

is not given by $\delta^I_l$, e.g., $e^{-i\delta^I_l} F_{20}$ is not real in the isospin one case. A similar remark applies to $F_3$.

### 5.6 Previous experiments

We display in Table 5.1 the number of events collected so far. The data are obviously dominated by the work of Rosselet et al. [53], which measures the $\pi^+ \pi^-$ final state.
with good statistics. The authors parametrize the form factors as

\[ F = f_s e^{i\delta_0} + f_p e^{i\delta_1} \cos \theta + \text{D-wave} \]
\[ G = g e^{i\delta_1} + \text{D-wave} \]
\[ H = h e^{i\delta_1} + \text{D-wave} \]  \hspace{1cm} (5.34)

with \( f_s, f_p, g \) and \( h \) assumed to be real\(^6\). Furthermore, they put \( m_e = 0 \), such that the form factors \( R \) and \( F_4 \) drop out in the decay distribution. Despite the good statistics, the experiment has not been able to separate out the full kinematic behaviour of the matrix elements. Therefore certain approximations/assumptions had to be made. For example, no dependence on \( s_l \) was seen within the limits of the data, so that the results were quoted assuming that such a dependence is absent. Similarly, \( f_p \) was found to be compatible with zero, and hence put equal to zero when the final result for \( g \) was derived. A dependence on \( s_\pi \) was seen, and found to be compatible with

\[ f_s(q^2) = f_s(0)[1 + \lambda_f q^2] \]
\[ g(q^2) = g(0)[1 + \lambda_g q^2] \]
\[ h(q^2) = h(0)[1 + \lambda_h q^2] \]
\[ q^2 = (s_\pi - 4M_\pi^2)/4M_\pi^2 \]  \hspace{1cm} (5.35)

with

\[ \lambda_f = \lambda_g = \lambda_h = \lambda. \]  \hspace{1cm} (5.36)

These approximations to the form factors do not agree completely with what is found in the theoretical predictions. Dependence on \( s_l \) and non-zero values for higher partial waves all occur in the theoretical results.

The experimental results for the threshold values and the slopes of the form factors are \[53\]

\[ f_s(0) = 5.59 \pm 0.14 \]
\[ g(0) = 4.77 \pm 0.27 \]
\[ h(0) = -2.68 \pm 0.68 \]
\[ \lambda = 0.08 \pm 0.02. \]  \hspace{1cm} (5.37)

We have used \[3\] \( |V_{us}| = 0.22 \) in transcribing these results. (We note that from Eqs. (5.34 - 5.37) and \( f_p = 0 \) we obtain \( \Gamma_{K_{e4}} = (2.94 \pm 0.16) \cdot 10^3 \text{ sec}^{-1}. \) This value must be compared with \( \Gamma_{K_{e4}} = (3.26 \pm 0.15) \cdot 10^3 \text{ sec}^{-1} \) obtained in the same experiment.) In addition to the threshold values (5.37) of the form factors, the phase shift difference \( \delta = \delta_0^0 - \delta_1^1 \) was determined \[53\] in five energy bins. The S-wave scattering length \( a_0^0 \) was then extracted by using a model of Basdevant, Froggatt and Petersen \[58\].

\(^6\)Note that, according to what is said in the previous subsection, the terms denoted by "D-wave" in Eq. (5.34) all contain (complex) contributions which are proportional to \( P_l(\cos \theta_\pi), l \geq 0. \)
This model is based on solutions to Roy equations. The result for the scattering length is

$$a_0^0 = 0.28 \pm 0.05.$$  \hspace{1cm} (5.38)

A study by [59], based on a more recent solution to Roy equations, gives

$$a_0^0 = 0.26 \pm 0.05.$$  \hspace{1cm} (5.39)

Turning now to the $\pi^0\pi^0\bar{e}\nu_e$ channel, we consider the following recent data (based on $729 \pm 15$ events) [60]:

$$\text{BR}(K_L \to \pi^0\pi^0\bar{e}\nu_e) = (5.16 \pm 0.22 \pm 0.07) \cdot 10^{-5}.$$  \hspace{1cm} (5.40)

The group also measured the $G$ form factor. Defining

$$G_{0-} = G_0(1 + \lambda g q^2) e^{i\delta_{01}},$$  \hspace{1cm} (5.41)

they find

$$G_0 = 7.8 \pm 0.7 \pm 0.2,$$

$$\lambda_g = 0.014 \pm 0.087 \pm 0.070.$$  \hspace{1cm} (5.42)

The slope agrees within the errors with the value (5.37) found by Rosselet et al. [53].

To compare the value of the form factor at threshold, we use the isospin prediction

$$|g(0)| = |G_0|/\sqrt{2} = 5.5 \pm 0.5,$$  \hspace{1cm} (5.43)

which is not incompatible with $g(0) = 4.77 \pm 0.27$ in eq. (5.37). (Here we have used $|V_{us}| = 0.22$ to transcribe the data. Furthermore, we assume that the form factor $G_{0-}$ measured in Ref. [60] indeed has to be divided by $\sqrt{2}$ for the comparison with [53]. This is not quite clear to us reading [60].)

Finally for the channel $\pi^0\pi^0\bar{e}\nu_e$, we consider the rate [3]

$$\Gamma_{K^+ \to \pi^0\pi^0\bar{e}\nu_e} = \left(1.70^{+0.34}_{-0.29}\right) \cdot 10^3 \text{sec}^{-1}.$$  \hspace{1cm} (5.44)

The kinematic dependence of the form factors on the variables $s_\pi, s_t$ and $\theta_\pi$ has not yet been resolved experimentally in this decay. In order to proceed, we assume that the form factors in this channel are independent of $\theta_\pi$, e.g., $F_{00} = F_{00}(s_\pi, t + u)$ etc. As a result of this assumption, $G_{00}$ and $H_{00}$ vanish by Bose statistics. The contribution from $R_{00}$ is completely negligible in the electron mode, and the contribution from the anomaly form factor to the decay (5.44) is tiny. We neglect it altogether, as a result of which the above decay is fully determined by $F_{00}$. We write

$$F_{00} = F_0(1 + \lambda q^2) e^{i\delta_0},$$  \hspace{1cm} (5.45)

and obtain for the rate

$$2\Gamma_{K^+ \to \pi^0\pi^0\bar{e}\nu_e} = |F_0V_{us}|^2(2.01 + 1.7\lambda + O(\lambda^2)) \cdot 10^3 \text{sec}^{-1}.$$  \hspace{1cm} (5.46)
This finally gives with $\lambda = 0.08$

$$|F_0| = 5.72^{+0.57}_{-0.49}, \quad (5.47)$$

which compares very well with the isospin prediction

$$|F_0| = |f_s(0)| = 5.59 \pm 0.14. \quad (5.48)$$

### 5.7 Theory

The theoretical predictions of $K_{14}$ form factors have a long history which started in the sixties with the current algebra evaluation of $F$, $G$, $R$ and $H$. For an early review of the subject and for references to work prior to CHPT we refer the reader to [34] (see also [35]). Here we concentrate on the evaluation of the form factors in the framework of CHPT [54, 55, 61, 62].

#### 5.7.1 Form factors at tree level

The chiral representation of the form factors at leading order was originally given by Weinberg [63].

$$F = G = \frac{M_K}{\sqrt{2}F_\pi} = 3.74, \quad \text{(5.49)}$$

$$R = \frac{M_K}{2\sqrt{2}F_\pi} \left( \frac{s_\pi + \nu}{s_t - M_K^2} + 1 \right), \quad H = 0. \quad (5.49)$$

The next-to-leading order corrections are displayed below, and the later sections contain an estimate of yet higher-order contributions. Here we note that the total decay rates which follow from Eq. (5.49) are typically a factor of two (or more) below the data. As an example, consider the channel $K^+ \to \pi^+\pi^-e^+\nu_e$. Using (5.49), the total decay rate becomes $1297 \text{ sec}^{-1}$, whereas the experimental value is $3160 \pm 140 \text{ sec}^{-1}$ [8].

#### 5.7.2 Form factors at one loop

The one-loop result for $F$ [54, 55] may be written in the form

$$F(s_\pi, t, u) = \frac{M_K}{\sqrt{2}F_\pi} \left\{ 1 + \frac{1}{F_\pi^2} (U_F + P_F + C_F) + O(E^4) \right\}. \quad (5.50)$$

If not stated otherwise, we use $F_\pi = 93.2 \text{ MeV}$, $|V_{us}| = 0.22$ and $(M_\pi, M_K) = (139.6, 493.6) \text{ MeV}$, (135, 493.6) MeV and (137, 497.7) MeV for the decays (5.1), (5.2) and (5.3), respectively.
The contribution $U_F(s_\pi, t, u)$ denotes the unitarity correction generated by the one-loop graphs which appear at order $E^4$ in the low-energy expansion. Its expression will be given in appendix D.

The contribution $P_F(s_\pi, t, u)$ is a polynomial in $s_\pi, t, u$ obtained from the tree graphs at order $E^4$. We find

$$P_F(s_\pi, t, u) = \sum_{i=1}^{9} p_{i,F}(s_\pi, t, u)L_i^r, \quad (5.51)$$

where

$$
\begin{align*}
p_{1,F} &= 32(s_\pi - 2M_\pi^2), \\
p_{2,F} &= 8(M_K^2 + s_\pi - s_l), \\
p_{3,F} &= 4(M_K^2 - 3M_\pi^2 + 2s_\pi - t), \\
p_{4,F} &= 32M_\pi^2, \\
p_{5,F} &= 4M_\pi^2, \\
p_{9,F} &= 2s_l.
\end{align*}
(5.52)
$$

The remaining coefficients $p_{i,F}$ are zero.

The contributions $C_F$ contain logarithmic terms, independent of $s_\pi, t$ and $u$: 

$$C_F = \frac{1}{256\pi^2} \left[5M_\pi^2 \ln \frac{M_\pi^2}{\mu^2} - 2M_K^2 \ln \frac{M_K^2}{\mu^2} - 3M_\eta^2 \ln \frac{M_\eta^2}{\mu^2}\right]. \quad (5.53)$$

The corresponding decomposition of the form factor $G$ is [54], [55]

$$G(s_\pi, t, u) = \frac{M_K}{\sqrt{2F_\pi}} \left\{1 + \frac{1}{F_\pi^2}(U_G + P_G + C_G) + O(E^4)\right\}, \quad (5.54)$$

For the expression of $U_G$ see appendix D. The polynomials

$$P_G = \sum_{i=1}^{9} p_{i,G}(s_\pi, t, u)L_i^r \quad (5.55)$$

are

$$
\begin{align*}
p_{2,G} &= 8(t - u), \\
p_{3,G} &= 4(t - M_K^2 - M_\pi^2), \\
p_{5,G} &= 4M_\pi^2, \\
p_{9,G} &= 2s_l.
\end{align*}
(5.56)$$
The remaining \( p_{i,G} \) vanish. The logarithms contained in \( C_G \) are

\[ C_G = -C_F. \tag{5.57} \]

The form factor \( R \) contains a pole part \( Z(s_\pi, t, u)/(s_l - M_K^2) \) and a regular piece \( Q \). [Since the axial current acts as an interpolating field for a kaon, the residue of the pole part is related to the \( KK \to \pi\pi \) amplitude in the standard manner.] We write

\[
R = \frac{M_K}{2\sqrt{2}F_\pi} \left\{ \frac{Z}{s_l - M_K^2} + Q + O(E^4) \right\},
\]

\[
I = B_I + \frac{1}{F_\pi^2}(U_I + P_I + C_I), \quad I = Z, Q. \tag{5.58}
\]

According to (5.49), the Born terms \( B_I \) are \[63\]

\[
B_Z = s_\pi + \nu, \\
B_Q = 1.
\tag{5.59}
\]

The one-loop corrections have been worked out in Ref. \[62\]. The unitarity corrections \( U_I \) are displayed in the appendix \[\text{D}]. The residues \( P_Z \) and \( C_Z \) are

\[
P_Z(s_\pi, t, u) = \sum_{i=1}^9 p_{i,Z}(s_\pi, t, u)L_i^r, \tag{5.60}
\]

with

\[
p_{1,Z} = 32(s_\pi - 2M_K^2)(s_\pi - 2M_\pi^2), \\
p_{2,Z} = 8(s_\pi^2 + \nu^2), \\
p_{3,Z} = -2\left[2(\nu + 4\Sigma)s_\pi - 5s_\pi^2 - \nu^2 - 16M_K^2M_\pi^2\right], \\
p_{4,Z} = 32\left[\Sigma s_\pi - 4M_K^2M_\pi^2\right], \\
p_{5,Z} = 4\left[(s_\pi + \nu)\Sigma - 8M_K^2M_\pi^2\right], \\
p_{6,Z} = 128M_K^2M_\pi^2, \\
p_{8,Z} = 64M_K^2M_\pi^2, \\
\Sigma = M_K^2 + M_\pi^2. \tag{5.61}
\]

The remaining \( p_{i,Z} \) vanish. The logarithms in \( C_Z \) are

\[
C_Z = -\frac{M_K^2 - M_\pi^2}{128\pi^2} \left[ 3M_\pi^2 \ln \frac{M_\pi^2}{\mu^2} - 2M_K^2 \ln \frac{M_K^2}{\mu^2} - M_\eta^2 \ln \frac{M_\eta^2}{\mu^2} \right]. \tag{5.62}
\]

For the nonpole part \( Q \) we find:
\[ P_Q(s_\pi, t, u) = \sum_{i=1}^{9} p_{i,Q}(s_\pi, t, u) L^r_i , \]  
\[ \text{(5.63)} \]

with

\[
\begin{align*}
    p_{1,Q} &= 32(s_\pi - 2M_\pi^2) , \\
    p_{2,Q} &= 8(M_K^2 - s_1) , \\
    p_{3,Q} &= 2 \left[ 4(s_\pi - 2M_\pi^2) + M_K^2 - s_1 \right] , \\
    p_{4,Q} &= 32M_\pi^2 , \\
    p_{5,Q} &= 4\Sigma , \\
    p_{9,Q} &= 2 \left[ (s_\pi + \nu) - (M_K^2 - s_1) \right] . \\
\end{align*}
\]

\[ \text{(5.64)} \]

The remaining \( p_{i,Q} \) vanish. The logarithms in \( C_Q \) are

\[
C_Q = \frac{1}{128\pi^2} \left[ 5M_\pi^2 \ln \frac{M_\pi^2}{\mu^2} - 2M_\pi^2 \ln \frac{M_K^2}{\mu^2} - 3M_\eta^2 \ln \frac{M_\eta^2}{\mu^2} \right] .
\]

\[ \text{(5.65)} \]

The first nonvanishing contribution in the chiral expansion of the form factor \( H \) is due to the chiral anomaly \[12\]. The prediction is \[64\]

\[
H = -\frac{\sqrt{2}M_K^3}{8\pi^2 F_\pi^3} = -2.66 ,
\]

\[ \text{(5.66)} \]

in excellent agreement with the experimental value \[53\] \( H = -2.68 \pm 0.68 \). The next-to-leading order corrections to \( H \) have also been calculated \[65\]. If the new low-energy parameters are estimated using the vector mesons only, these corrections are small.

The results for \( F, G \) and \( R \) must satisfy two nontrivial constraints: i) Unitarity requires that \( F, G \) and \( R \) contain, in the physical region \( 4M_\pi^2 \leq s_\pi \leq (M_K - m_1)^2 \), imaginary parts governed by \( S \)- and \( P \)-wave \( \pi\pi \) scattering [these imaginary parts are contained in the functions \( \Delta_0(s_\pi), \Delta_1(s_\pi) \)]. ii) The scale dependence of the low-energy constants \( L_i^r \) must be compensated by the scale dependence of \( U_{F,G,Z,Q} \) and \( C_{F,G,Z,Q} \) for all values of \( s_\pi, t, u, M^2_\pi, M_K^2 \). [Since we work at order \( E^4 \) in the chiral expansion, the meson masses appearing in the above expressions satisfy the Gell-Mann-Okubo mass formula.] We have checked that these constraints are satisfied.

Because the one-loop contributions are rather large, one expects still substantial corrections from higher orders. In the following section, we therefore first estimate the effects from higher orders in the chiral expansion, using then this improved representation for the form factors in a comparison with the data.
5.7.3 Form factors beyond one loop

To investigate the importance of higher-order terms, we employ the method developed in Ref. [66]. It amounts to writing a dispersive representation of the partial wave amplitudes, fixing the subtraction constants using chiral perturbation theory. Here, we estimate the higher-order terms in the S-wave projection of the amplitude $F_1$,

$$f(s_\pi, s_l) = (4\pi X)^{-1} \int d\Omega F_1(s_\pi, t, s_l) ,$$

because this form factor plays a decisive role in the determination of $L_{r_1}^r, L_{r_2}^r$ and $L_3$, and it is influenced by S-wave $\pi\pi$ scattering which is known [67] to produce substantial corrections.

5.7.4 Analytic properties of partial waves

Only the crossing-even part

$$F_1^+ = XF^+ + \sigma_\pi(PL) \cos \theta_\pi \cdot G^-$$

contributes in the projection (5.67). The partial wave $f$ has the following analytic properties:

1. At fixed $s_l$, it is analytic in the complex $s_\pi$-plane, cut along the real axis for $\text{Re} \ s_\pi \geq 4M_\pi^2$ and $\text{Re} \ s_\pi \leq 0$.
2. In the interval $0 \leq s_\pi \leq 4M_\pi^2$, it is real.
3. In $4M_\pi^2 \leq s_\pi \leq 16M_\pi^2$, its phase coincides with the isospin zero S-wave phase $\delta_0^0$ in elastic $\pi\pi$ scattering,

$$f_+ = e^{2i\delta_0^0} f_+, f_\pm = f(s_\pi \pm i\epsilon, s_l).$$

The proof of these properties is standard [68]. Here we only note that the presence of the cut for $s_\pi \leq 0$ follows from the relations

$$t = M_\pi^2 + \frac{M_K^2 + s_l - s_\pi}{2} - \sigma_\pi X \cos \theta_\pi ,$$

$$t(\cos \theta_\pi = -1, s_\pi < 0) \geq (M_K + M_\pi)^2.$$ 

Since $F^+$ and $G^-$ have cuts at $t \geq (M_K + M_\pi)^2$, the claim is proven.

5.7.5 Unitarization
We introduce the Omnès function
\[ \Omega(s_\pi) = \exp \left[ \frac{s_\pi}{\pi} \int_{4M_\pi^2}^{\Lambda^2} \frac{ds \, \delta_0^0(s)}{s \, s - s_\pi} \right], \tag{5.71} \]
where \( \Lambda \) will be chosen of the order of 1 GeV below. According to (5.69), multiplication by \( \Omega^{-1} \) removes the cut in \( f \) for \( 4M_\pi^2 \leq s_\pi \leq 16M_\pi^2 \). Consider now
\[ f = f_L + f_R, \tag{5.72} \]
where \( f_L(f_R) \) has only the left-hand (right-hand) cut, and introduce
\[ v = \Omega^{-1}(f - f_L). \tag{5.73} \]
Then \( v \) has only a right-hand cut, and we may represent it in a dispersive way,
\[ v = v_0 + v_1 s_\pi + \frac{s_\pi^2}{\pi} \int_{4M_\pi^2}^{\infty} \frac{ds \, \text{Im}\Omega^{-1}(f - f_L)}{s - s_\pi}. \tag{5.74} \]
We expect the contributions from the integral beyond 1 GeV to be small. Furthermore, \( \Omega^{-1}f \) is approximately real between \( 16M_\pi^2 \) and 1 GeV, as a result of which one has
\[ v = v_0 + v_1 s_\pi - \frac{s_\pi^2}{\pi} \int_{4M_\pi^2}^{\Lambda^2} \frac{ds \, f_L \text{Im}\Omega^{-1}}{s - s_\pi}. \tag{5.75} \]
For given \( v_0, v_1, f_L \) and \( \Omega \), the form factor \( f \) is finally obtained from
\[ f = f_L + \Omega v. \tag{5.76} \]
The behaviour of \( f_L \) at \( s_\pi \to 0 \) is governed by the large-\( |t| \) behaviour of \( F^+ \) and \( G^- \), see (5.70). Therefore, instead of using CHPT to model \( f_L \), we approximate the left-hand cut by resonance exchange. To pin down the subtraction constants \( v_0, v_1 \), we require that the threshold expansion of \( f \) and \( f_{\text{CHPT}} \) agree up to and including terms of order \( O(E^2) \). For a specific choice of \( f_L \), this fixes \( v_0, v_1 \) in terms of the quantities which occur in the one-loop representation of \( F^+ \) and \( G^- \). In the case where \( f_L = 0 \), \( f \) has then a particularly simple form at \( s_l = 0 \),
\[
\begin{align*}
\left. f(s_\pi, s_l = 0) \right|_{f_L=0} &= \Omega(v_0 + v_1 s_\pi), \\
v_0 &= \frac{M_K}{\sqrt{2}F_\pi} \left\{ 1.05 + \frac{1}{F_\pi^2} \left[ -64M_\pi^2 L_1^r + 8M_K^2 L_2^r \\
& \quad + 2(M_K^2 - 8M_\pi^2)L_3 + \frac{2}{3}(M_K^2 - 4M_\pi^2)(4L_2^r + L_3) \right] \right\}, \\
v_1 &= \frac{M_K}{\sqrt{2}F_\pi} \left\{ 0.38 + \frac{1}{F_\pi^2} \left[ 32L_1^r + 8L_2^r + 10L_3 \\
& \quad - \frac{2}{3} \frac{2M_K^2 - 4M_\pi^2}{4M_\pi^2}(4L_2^r + L_3) \right] \right\}. \tag{5.77}
\end{align*}
\]
The details of the evaluation of $f_L, v_0$ and of $v_1$ may be found in Ref. [62].

In the partial wave $f$, the effects of the final-state interactions are substantial, because they are related to the $I = 0, S$-wave $\pi\pi$ phase shift. On the other hand, for the leading partial wave in $G^+ = g e^{i\delta_p} + \cdots$, these effects are reduced, because the phase $\delta_p$ is small at low energies. We find it more difficult to assess an estimate for the higher-order corrections in this case – we come back to this point in the following sections.

We add a remark concerning the choice of the subtraction point in the Omnès function (5.71). To remove the right-hand cut in $f$, the modified Omnès function

$$\Omega(s_\pi, s_0) = \exp \left( \frac{s_\pi - s_0}{\pi} \right) \int_{4M_\pi^2}^{\Lambda^2} \frac{ds}{s-s_0} \frac{\delta_0^0(s)}{s-s_\pi}$$

would do as well, with any value of $s_0 \leq 4M_\pi^2$. To illustrate the meaning of $s_0$, we consider for simplicity the form factor $f$ in the case where $f_L = 0$. The choice $s_0 = 4M_\pi^2$ then amounts to the statement that, at threshold, there are no contributions from two loops and beyond by fiat. We consider this to be rather unlikely. (For a different opinion see [69].) On the other hand, we have checked that our results do not vary significantly if $s_0$ is taken of the order of the pion mass squared, $|s_0| \leq M_\pi^2$.

### 5.8 Determination of $L_1, L_2$ and $L_3$

To illustrate the usefulness of forthcoming more accurate $K_{l4}$ data, we determine here the low-energy constants $L_1, L_2$ and $L_3$ from data on $K^+ \rightarrow \pi^+\pi^- e^+\nu_e$ decays and on $\pi\pi \rightarrow \pi\pi$ threshold parameters, using the improved $S$-wave amplitude $f$ set up above. For a comparison with earlier work [55], we refer the reader to Ref. [62].

We perform fits to $f_s(0), \lambda_f, g(0)$ as given in (5.37) and to the $\pi\pi$ threshold parameters listed in table 5.2. We introduce for this purpose the quantities

$$\bar{f}(s_\pi, s_l) = (4\pi X)^{-1} \int d\Omega F_1(s_\pi, t, s_l) = |f(s_\pi, s_l)| ,$$

$$\bar{g}(s_\pi, s_l) = \frac{3}{8\pi} \int d\Omega \sin^2 \theta \pi G(s_\pi, t, s_l) \right| ,$$

where the factor $3/2 \sin^2 \theta$ appears because $G$ is expanded in derivatives of Legendre polynomials. Below, we identify $[f_s(0), g(0)]$ with $[\bar{f}(4M_\pi^2, s_l), \bar{g}(4M_\pi^2, s_l)]$, which depend on $s_l$. Furthermore, we compare the slope $\lambda_f$ with

$$\bar{\lambda}_f(s_\pi, s_l) = \bar{f}(s_\pi, s_l) - \bar{f}(4M_\pi^2, s_l) \frac{4M_\pi^2}{s_\pi - 4M_\pi^2} ,$$

which depends on both $s_\pi$ and $s_l$. We use these dependences to estimate systematic uncertainties in the determination of the low-energy couplings. [In future high-statistics experiments, the $s_l$-dependence of the form factors will presumably be resolved. It will be easy to adapt the procedure to this case.]
Table 5.2: Results of fits with one-loop and unitarized form factors, respectively. The errors quoted for the $L_i$'s are statistical only. The $L_i$ are given in units of $10^{-3}$ at the scale $\mu = M_\rho$, the scattering lengths $a_i$ and the slopes $b_i$ in appropriate powers of $M_{\pi^+}$.

| $K_{e4}$ data alone | $K_{e4}$ and $\pi\pi$ data | experiment |
|---------------------|-----------------------------|------------|
|                     | one-loop | unitarized | one-loop | unitarized | [71]         |

We have used MINUIT [70] to perform the fits. The results for the choice $s_t = 0, s_\pi = 4.4M_\pi^2$ are given in table 5.2. In the columns denoted by “one-loop”, we have evaluated $\bar{f}, \bar{g}$ and $\bar{\lambda}_f$ from the one-loop representation given above [71]. In the fit with the unitarized form factor (columns 3 and 5), we have evaluated $\bar{f}$ from Eqs. (5.76), inserting in the Omnès function the parametrization of the $\pi\pi$ S-wave phase shift proposed by Schenk [72, solution B]. For the form factor $G$, we have again used the one-loop representation. The statistical errors quoted for the $L_i$’s are the ones generated by the procedure MINOS in MINUIT and correspond to an increase of $\chi^2$ by one unit.

A few remarks are in order at this place.

1. It is seen that the overall description of the $\pi\pi$ scattering data is better using the unitarized form factors, in particular so for the $D$-wave scattering lengths.

2. The errors quoted do not give account of the fact that the simultaneous determination of the three constants produces a strong correlation between them. To illustrate this point we note that, while the values of the $L_i$’s in column 4 and 5 are apparently consistent with each other within one error bar, the $\chi^2$ in column 5 increases from 4.9 to 30.7 if the $L_i$’s from column 4 are used in

---

*We always use for $L_i^a, \ldots, L_i^9$ the values quoted in table 1 of Ref. [2].*
the evaluation of \( \chi^2 \) in column 5. (For a discussion about the interpretation of the errors see [70]).

3. The low-energy constants \( \bar{l}_1, \bar{l}_2 \) which occur in \( SU(2)_L \times SU(2)_R \) analyses may be evaluated from a given set of \( L^r_1, L^r_2 \) and \( L_3 \) [44]. Their value changes in a significant way by using the unitarized amplitude instead of the one-loop formulae: the values for \( (\bar{l}_1, \bar{l}_2) \) in column 4 and 5 are \((-0.5 \pm 0.88, 6.4 \pm 0.44)\) and \((-1.7 \pm 0.85, 6.0 \pm 0.4)\), respectively.

4. \( L^r_1, L^r_2 \) and \( L_3 \) are related to \( \pi\pi \) phase shifts through sum rules [73, 74]. In principle, one could take these constraints into account as well [11]. We do not consider them here, because we find it very difficult to assess a reliable error for the integrals over the total \( \pi\pi \) cross sections which occur in those relations.

The statistical error in the data is only one source of the uncertainty in the low-energy constants, which are in addition affected by the ambiguities in the estimate of the higher-order corrections. These systematic uncertainties have several sources:

i) Higher-order corrections to \( \tilde{g} \) have not been taken into account.

ii) The determination of the contribution from the left-hand cut is not unique.

iii) The quantities \( \bar{f} \) and \( \tilde{g} \) depend on \( s_l \), and \( \tilde{\lambda}_f \) is a function of both \( s_l \) and \( s_\pi \).

iv) The Omnès function depends on the elastic \( \pi\pi \) phase shift and on the cutoff \( \Lambda \) used.

We have considered carefully these effects [52], and found that the best determination of \( L^r_1, L^r_2 \), and \( L_3 \) which takes them into account is

\[
\begin{align*}
10^3 L^r_1(M_\rho) &= 0.4 \pm 0.3 , \\
10^3 L^r_2(M_\rho) &= 1.35 \pm 0.3 , \\
10^3 L_3 &= -3.5 \pm 1.1 .
\end{align*}
\] (5.80)

These values are the ones quoted in table 1 in Ref. [2]. For \( SU(2)_L \times SU(2)_R \) analyses it is useful to know the corresponding values for the constants \( \bar{l}_1 \) and \( \bar{l}_2 \),

\[
\begin{align*}
\bar{l}_1 &= -1.7 \pm 1.0 , \\
\bar{l}_2 &= 6.1 \pm 0.5 .
\end{align*}
\] (5.81)

The value and uncertainties in these couplings play a decisive role in a planned experiment [73] to measure the lifetime of \( \pi^+\pi^- \) atoms, which will provide a completely independent measurement of the \( \pi\pi \) scattering lengths \( |a_0^0 - a_0^2| \).

\[9\]We thank B. Moussallam for pointing this out to us.
One motivation for the analysis in [54, 55] was to test the large-$N_C$ prediction $L_2^r = 2L_1^r$. The above result shows that a small non-zero value is preferred. To obtain a clean error analysis, we have repeated the fitting procedure using the variables

\[
X_1 = L_2^r - 2L_1^r - L_3 , \\
X_2^r = L_2^r , \\
X_3 = (L_2^r - 2L_1^r)/L_3 .
\]  

(5.82)

We performed a fit to $K_{e4}$ and $\pi\pi$ data, including the theoretical error in $G$ as discussed above, and found

\[
X_1 = (4.8 \pm 0.8) \cdot 10^{-3} , \\
X_3 = -0.17^{+0.12}_{-0.22} .
\]  

(5.83)

The result is that the large-$N_C$ prediction works remarkably well.

5.9 Predictions

In this section we make several predictions using the $L_i^r$'s from table 1 in Ref. [2]. It is clear that new and more accurate data on $K_{e4}$ will allow for a better determination of $L_1^r, L_2^r$ and $L_3$, and may correspondingly modify our predictions. However, unless a dramatic change in the values of these constants occurs, the modified predictions will be within the errors that we give.

Whereas the slope $\lambda_g$ was assumed to coincide with the slope $\lambda_f$ in the final analysis of the data in Ref. [53], these two quantities may differ in the chiral representation. Furthermore, our amplitudes allow us to evaluate partial and total decay rates. In this section, we consider the slope $\lambda_g$ and the total rates.

The slope $\lambda_g$

We consider the form factor $\bar{g}$ introduced in (5.78) and determine its slope $\lambda_g$

\[
\bar{g}(s_\pi, s_t) = \bar{g}(4M_\pi^2, sl)(1 + \lambda_g(s_l)q^2 + O(q^4)) \]  

(5.84)

from the one-loop expression for $G$. The result is $\lambda_g(0) = 0.08$. As the slope is a one-loop effect, higher-order corrections may affect its value substantially. For this reason, we have evaluated $\lambda_g$ also from the modified form factor obtained by using the complete resonance propagators (and the corresponding $L_i$'s), see Ref. [62]. The change is $\Delta \lambda_g = 0.025$. We believe this to be a generous error estimate and obtain in this manner

\[
\lambda_g(0) = 0.08 \pm 0.025 .
\]  

(5.85)

The central value indeed agrees with the slope $\lambda$ in (5.37).
Table 5.3: Approximations used to evaluate the total rates in table 5.4. Use of \( \bar{f} = \bar{f}_{\text{CHPT}}, \bar{g} = \bar{g}_{\text{CHPT}} \) reproduces the one-loop results in table 5.4 to about 1%.

a) \( K^+ \) decays

Total rates

Once the leading partial waves \( \bar{f} \) and \( \bar{g} \) are known from e.g. \( K^+ \to \pi^+\pi^-e^+\nu_e \) decays, the chiral representation allows one to predict the remaining rates within rather small uncertainties. We illustrate the procedure for \( K^+ \to \pi^0\pi^0e^+\nu_e \). According to Eq. (5.24), the relevant amplitude is determined by \( F^+, G^-, R^+ \) and \( H^- \). The contribution from \( H^- \) is kinematically strongly suppressed and completely negligible in all total rates, whereas the contribution from \( R \) is negligible in the electron modes. Using the chiral representation of the amplitudes \( F^+ \) and \( G^- \), we find that the rate is reproduced to about 1%, if one neglects \( G^- \) altogether and uses only the leading partial wave in the remaining amplitude, \( F_1^+ \approx -X\bar{f} \). From the measured form factor \( \bar{f} = 5.59(1 + 0.08q^2) \) we then find \( \Gamma_{K^+ \to \pi^0\pi^0e^+\nu_e} = 1625 \text{sec}^{-1} \). Finally, we estimate the error from

\[
\Delta \Gamma = \left\{ \left[ \Gamma(f_s(0) + \Delta f_s, \lambda_f) - \Gamma(f_s(0), \lambda_f) \right]^2 + \left[ \Gamma(f_s(0), \lambda_f + \Delta \lambda_f) - \Gamma(f_s(0), \lambda_f) \right]^2 \right\}^{1/2} = 90 \text{sec}^{-1},
\]

(5.86)

where \( \Delta f_s = 0.14, \Delta \lambda_f = 0.02 \). The final result for the rate is shown in the row
Table 5.4: Total decay rates in sec$^{-1}$. To evaluate the rates at one-loop accuracy, we have used the $L_i^r$'s from table 1 in Ref. [2]. The final predictions are evaluated with the amplitudes shown in table 5.3 using $f = 5.59(1 + 0.08q^2)$, $g = 4.77(1 + 0.08q^2)$. For the evaluation of the uncertainties in the rates see text.

a) $K^+$ decays

|                | $\pi^+\pi^-e^+\nu_e$ | $\pi^0\pi^0e^+\nu_e$ | $\pi^+\pi^-\mu^+\nu_\mu$ | $\pi^0\pi^0\mu^+\nu_\mu$ |

| experiment     | 998                    | $\pm 39 \pm 43$            |

“final prediction” in table 5.4, where we have also listed the tree and the one-loop result, together with the experimental data. The evaluation of the remaining rates is done in a similar manner – see table 5.3 for the simplifications used and table 5.4 for the corresponding predictions.

We have assessed an uncertainty due to contributions from $F_{\text{CHPT}}^-, R_{\text{CHPT}}$ in the following manner. i) We have checked that the results barely change by using the tree level expression for $R_{\text{CHPT}}$ instead of its one-loop representation. We conclude from this that the uncertainties in $R_{\text{CHPT}}$ do not matter. ii) The uncertainty from $F_{\text{CHPT}}^-$ is taken into account by adding to $\Delta \Gamma$ in quadrature the change obtained by evaluating $F_{\text{CHPT}}^-$ at $L_3 = -3.5 + 1.1 = -2.4$. iii) In $K^0$ decays, we have also added in quadrature the difference generated by evaluating the rate with $M_\pi = 135$ MeV.

The decay $K^0 \rightarrow \pi^0\pi^-e^+\nu_e$ has recently been measured [60] with considerably higher statistics than before [3]. We display the result for the rate in the first column of table 5.4b. The quoted errors correspond to the errors in the branching ratio [60] and do not include the uncertainty in the total decay rate quoted by the PDG [3].
Notice that the value for $L_3$ determined in (5.37) should be multiplied with $-1$.

5.10 Improvements at DAΦNE

The chiral analysis of $K_{l4}$ decays has been used so far for three purposes:

1. The $K_{e4}$ data from Ref. [53] allows one to make predictions for the slope of the $G$ form factor, for the total rates in all the channels and for the $\pi\pi$ scattering lengths. These are given in Eq. (5.85), in Table 5.4 and in Table 5.2, respectively.

2. The same $K_{e4}$ data allow one to test the large-$N_C$ prediction, see Eqs. (5.82) and (5.83).

3. The full set of $K_{e4}$ and $\pi\pi$ scattering data allows the best determination of the coefficients $L_1, L_2$ and $L_3$ in the chiral Lagrangian, see (5.80).

In the next generation of $K_{l4}$ decay experiments, there is the opportunity to improve the phenomenology of $K_{l4}$ (see Table 5.1):

1. A very useful innovation would be to analyze the experimental data with a modified chiral representation. In the latter, the full $S$- and $P$-wave parts of $F_1$ and $F_2$ could be inserted, using the chiral representation solely to describe the small background effects due to higher partial waves $l \geq 2$. To be more precise, one would take for $R$ and $H$ the one-loop chiral representation, whereas for $G$ one writes

$$G = g(s_\pi, s_l)e^{i\delta_p} + \Delta G, \quad \Delta G = G_{\text{CHPT}} - \frac{3}{8\pi} \int d\Omega \sin^2 \theta_{\pi}\, G_{\text{CHPT}}, \quad (5.87)$$

and similarly for $F$. The unknown amplitudes $g(s_\pi, s_l), f_s(s_\pi, s_l)$ and the phases $\delta_p, \delta_s$ would then be determined from the data. We have checked that, if the errors in the form factors determined in this manner can be reduced by e.g. a factor 3 with respect to the ones shown in (5.37), one could pin down particular combinations of $L_1, L_2$ and $L_3$ to considerably better precision than was shown above. This is true independently of an eventual improvement in the theoretical determination of the higher-order corrections in the form factor $G$ – which is a theoretical challenge in any case.

2. The present experimental uncertainty on $G$ is still too large to provide a precise value for the large-$N_C$ parameter $(L_2^e - 2L_1^e)/L_3$. ($K^0 \to \pi^0\pi^-e^+\nu_e$ decays are mainly sensitive to $G_{1+}^+$ which in turn can be used to pin down $L_3$. $K^+ \to \pi^0\pi^-e^+\nu_e$ is mainly sensitive to $F_{1+}^+$ which contains $L_1, L_2$ and $L_3$.)
3. The observation of all $K_{l4}$ reactions with high statistics could provide a cleaner separation of the various isospin amplitudes.

4. Finally, we come to a most important point. As we mentioned already, $K^+ \to \pi^+\pi^-e^+\nu_e$ has been used \cite{59} to determine the isoscalar $S$-wave scattering length with the result $a_0^0 = 0.26 \pm 0.05$. This value must be compared with the SU(2)×SU(2) prediction \cite{77,78} $a_0^0 = 0.20 \pm 0.01$. Low-energy $\pi\pi$ scattering is one of the few places where chiral symmetry allows one to make a precise prediction within the framework of QCD. In their article, Rosselet et al. comment about the discrepancy between $a_0^0 = 0.26 \pm 0.05$ and the leading-order result \cite{72} $a_0^0 = 0.16$ in the following manner: “... it appears that this prediction can be revised without any fundamental change in current algebra or in the partial conservation of axial-vector current \cite{80,81}.” Today, we know that this is not the case: The standard picture of the vacuum structure in QCD \cite{82} would have to be revised, should the central value $a_0^0 = 0.26$ be confirmed with a substantially smaller error. For recent work which supports this scenario see the contribution of Knecht and Stern in this Handbook \cite{83}.

$K_{l4}$ decays are – at present \cite{75} – the only available source of clean information on $\pi\pi$ $S$-wave scattering near threshold. We refer the reader to Ref. \cite{84} for a detailed analysis of the issue.
6 $K_{e5}$ decays

In this subsection we discuss the decays
\[ K^+ \rightarrow \pi^+ \pi^- \pi^0 e^+ \nu_e \]
\[ K^+ \rightarrow \pi^0 \pi^- \pi^+ e^+ \nu_e \]
\[ K^0 \rightarrow \pi^0 \pi^0 \pi^- e^+ \nu_e \]
\[ K^0 \rightarrow \pi^+ \pi^- \pi^- e^+ \nu_e . \]  

(6.1)

We do not consider isospin violating contributions and correspondingly set $m_u = m_d$, $\alpha = 0$.

6.1 Matrix elements and decay rates

The matrix element for $K \rightarrow \pi\pi\pi e^+\nu_e$ is
\[ T = \frac{G_F}{\sqrt{2}} V_{us}^* \bar{u}(p_\nu)\gamma_{\mu}(1 - \gamma_5)v(p_e)(V^\mu - A^\mu) , \]  

(6.2)

where
\[ I_{\mu} = \langle \pi(p_1)\pi(p_2)\pi(p_3)out|I_{\mu}^{1-15}(0)|K(p) > ; I = V, A. \]  

(6.3)

The decay rate is calculated from
\[ d\Gamma = \frac{1}{2M_K(2\pi)^{11}} \sum_{spans} \sum^2 |T|^2 dLIPS(p, p_e, p_\nu, p_1, p_2, p_3) . \]

6.2 Previous experiments

The Particle Data Group [3] quotes the upper bound
\[ BR(K^+ \rightarrow \pi^0 \pi^0 \pi^0 e^+\nu_e) < 3.5 \cdot 10^{-6} . \]

6.3 Theory

In CHPT, the leading-order contribution is given by the matrix element of the vector current. The corresponding rates are displayed in table (6.1). The smallness of these rates is due to the suppression of phase space. Indeed, consider the ratio of the four- and five-dimensional phase space volumes in the neutral pion channel,
\[ \frac{M_K^2 \int dLIPS(p, p_e, p_\nu, p_1, p_2)/2!}{(2\pi)^{12}} \frac{(2\pi)^{15}}{\int dLIPS(p, p_e, p_\nu, p_1, p_2, p_3)/3!} \simeq 2.3 \cdot 10^6 . \]

It agrees well with the ratio of the corresponding rates at tree level,

\[ \text{(6.4)} \]

10The material in this section is taken from Ref. 85.
Table 6.1: Rates of $K_{e5}$ decays, evaluated from the leading-order term.

| Decay                                      | Branching Ratio |
|--------------------------------------------|-----------------|
| $K^+ \to \pi^+ \pi^- \pi^0 e^+ \nu_e$     | $3 \cdot 10^{-12}$ |
| $K^+ \to \pi^0 \pi^0 \pi^0 e^+ \nu_e$    | $2.5 \cdot 10^{-12}$ |
| $K^0 \to \pi^0 \pi^0 \pi^- e^+ \nu_e$    | $12 \cdot 10^{-12}$ |
| $K^0 \to \pi^+ \pi^- \pi^0 e^+ \nu_e$    | $33 \cdot 10^{-12}$ |

\[
\frac{\Gamma(K^+ \to \pi^0 \pi^0 e^+ \nu_e)_{\text{tree}}}{\Gamma(K^+ \to \pi^0 \pi^0 \pi^0 e^+ \nu_e)_{\text{tree}}} \simeq 3.4 \cdot 10^6 .
\]

(The corresponding ratios for $K^+ \to \pi^0 e^+ \nu_e/K^+ \to \pi^0 \pi^0 e^+ \nu_e$ are $1.4 \cdot 10^4$ and $0.53 \cdot 10^4$ for phase space volumes and decay rates, respectively.) The contributions at order $p^4$ are due to i) the corrections to the matrix element of the vector current, and to ii) the matrix element of the axial current. The latter stems from the Wess-Zumino-Witten Lagrangian $L_{WZW}$. Both the local and nonlocal term in the anomalous action contribute. The nonlocal part is suppressed by the factor $m_e$ in the matrix element (in addition to the phase space suppression just mentioned).

Based on our experience with $K_{e4}$ decays, we expect the terms of order $p^4$ to enhance the above rates by roughly a factor of two to three.

### 6.4 Improvements at DAΦNE

According to the standard model, $K_{e5}$ decays are invisible at DAΦNE, but the existing upper limits can be improved significantly.

---

**Acknowledgements**

We thank G. Pancheri for the perfect organization of the DAΦNE Workshops and the INFN for the hospitality in Frascati. We have enjoyed numerous interesting discussions with the members of the working groups. We thank J. Beringer for checking traces in $K_{l2\gamma}$, M. Candusso for doing the contour plots and C. Riggenbach for providing us with numerical routines for $K_{l4}$. S. Blaser kindly allowed us to include his work [85] on $K_{e5}$ decays.
A Notation

The notation for phase space is the one without the factors of $2\pi$. For the decay rate of a particle with four momentum $p$ into $n$ particles with momenta $p_1, \ldots, p_n$ this is

$$d_{\text{LIPS}}(p; p_1, \ldots, p_n) = \delta^4(p - \sum_{i=1}^{n} p_i) \prod_{i=1}^{n} \frac{d^3 p_i}{2 p_i^0} . \quad (A.1)$$

We use a covariant normalization of one-particle states,

$$< \vec{p}' | \vec{p} > = (2\pi)^3 2p^0 \delta^3(\vec{p}' - \vec{p}) , \quad (A.2)$$

together with the spinor normalization

$$\bar{u}(p, r)u(p, s) = 2m\delta_{rs} . \quad (A.3)$$

The kinematical function $\lambda(x, y, z)$ is defined as

$$\lambda(x, y, z) = x^2 + y^2 + z^2 - 2(xy + yz + zx) . \quad (A.4)$$

We take the standard model in the current $\times$ current form, i.e., we neglect the momentum dependence of the $W$-propagator. The currents used in the text are:

$$V_{\mu}^{4-i5} = \bar{q} \gamma_{\mu} \gamma_5 \frac{1}{2}(\lambda_4 - i\lambda_5)q = \bar{q} \gamma_\mu u$$
$$A_{\mu}^{4-i5} = \bar{q} \gamma_{\mu} \frac{1}{2}(\lambda_4 - i\lambda_5)q = \bar{q} \gamma_\mu \gamma_5 u$$
$$V_{\mu}^{em} = \bar{q} \gamma_{\mu} Qq$$
$$Q = \text{diag}(2/3, -1/3, -1/3) . \quad (A.5)$$

The numerical values used in the programs are the physical masses for the particles as given by the Particle Data Group [3]. In addition we have used the values for the decay constants derived from the most recent measured charged pion and kaon semileptonic decay rates[3, 26]:

$$F_\pi = 93.2 \text{ MeV}$$
$$F_K = 113.6 \text{ MeV} . \quad (A.6)$$

We do not need values for the quark masses. For the processes considered in this report we can always use the lowest order relations to rewrite them in terms of the pseudoscalar meson masses (see Ref. [2]). For the KM matrix element we used the central value $|V_{us}| = 0.220$ of Ref. [3]. The numerical values for the $L^*_i(M_\rho)$ are those given in table 1 in Ref. [2].

The number of events quoted for DAΦNE are based on a luminosity of $5 \cdot 10^{32} \text{ cm}^{-2}\text{s}^{-1}$, which is equivalent [4] to an annual rate of $9 \cdot 10^9 (1.1 \cdot 10^9)$ tagged $K^\pm (K_L)$ (1 year = $10^7 \text{ s}$ assumed).
Whenever we quote a branching ratio for a semileptonic $K^0$ decay, it stands for the branching ratio of the corresponding $K_L$ decay, e.g.,

$$ BR(K^0 \to \pi^- l^+ \nu) \equiv BR(K_L \to \pi^\pm l^\mp \nu) . $$

(A.7)

We use the Condon-Shortley phase conventions throughout.
B Loop integrals

In this appendix we define the functions appearing in the loop integrals used in the text. First we define the functions needed for loops with two propagators, mainly in the form given in Ref. [44]. We consider a loop with two masses, \( M \) and \( m \). All needed functions can be given in terms of the subtracted scalar integral

\[
\bar{J}(t) = J(t) - J(0),
\]

with \( t = k^2 \). The functions used in the text are then:

\[
\begin{align*}
\bar{J}(t) & = -\frac{1}{16\pi^2} \int_0^1 dx \log \frac{M^2 - tx(1-x) - \Delta x}{M^2 - \Delta x} \\
& = \frac{1}{32\pi^2} \left\{ 2 + \frac{\Delta}{t} \log \frac{m^2}{M^2} - \frac{\Sigma}{\Delta} \log \frac{m^2}{M^2} - \frac{\sqrt{\lambda}}{t} \log \frac{(t + \sqrt{\lambda})^2 - \Delta^2}{(t - \sqrt{\lambda})^2 - \Delta^2} \right\}, \\
J^*(t) & = \bar{J}(t) - 2k, \\
M^*(t) & = \frac{1}{12t} \left\{ t - 2\Sigma \right\} \bar{J}(t) + \frac{\Delta^2}{3t^2} \bar{J}(t) + \frac{1}{288\pi^2} - \frac{k}{6} \\
& - \frac{1}{96\pi^2 t} \left\{ \Sigma + 2 \frac{M^2m^2}{\Delta} \log \frac{m^2}{M^2} \right\}, \\
L(t) & = \frac{\Delta^2}{4t} \bar{J}(t), \\
K(t) & = \frac{\Delta}{2t} \bar{J}(t), \\
H(t) & = \frac{2}{3} \frac{L_0}{F^2} t + \frac{1}{F^2} \left[ tM^*(t) - L(t) \right], \\
\Delta & = M^2 - m^2, \\
\Sigma & = M^2 + m^2, \\
\lambda & = \lambda(t, M^2, m^2) = (t + \Delta)^2 - 4tM^2.
\end{align*}
\]

In the text these are used with subscripts,

\[
\bar{J}_{ij}(t) = \bar{J}(t) \quad \text{with} \quad M = M_i, m = M_j
\]

and similarly for the other symbols. The subtraction point dependent part is contained in the constant \( k \)

\[
k = \frac{1}{32\pi^2} \frac{M^2 \log \left( \frac{M^2}{\mu^2} \right) - m^2 \log \left( \frac{m^2}{\mu^2} \right)}{M^2 - m^2},
\]

where \( \mu \) is the subtraction scale.
In addition, in subsection 4 these functions and symbols appear in a summation over loops $I$ with

$$J_I(t) = J(t) \quad \text{with} \quad M = M_I, m = m_I;$$
$$\Sigma_I = M_I^2 + m_I^2 \quad (B.5)$$

and again similarly for the others. There the combination $B_2$ appears as well:

$$B_2(t, M^2, m^2) = B_2(t, m^2, M^2)$$
$$= \frac{1}{288\pi^2} (3\Sigma - t) - \frac{\lambda(t, M^2, m^2)J(t)}{12t} + \frac{t\Sigma - 8M^2m^2}{384\pi^2\Delta} \log \frac{M^2}{m^2}.$$  

The last formula to be defined is the three propagator loop integral function $C(t_1, t_2, M^2, m^2)$ where one of the three external momenta has zero mass and two of the propagators have the same mass $M$. Here $t_1 = (q_1 + q_2)^2$, $t_2 = q_2^2$ and $q_1^2 = 0$.

$$C(t_1, t_2, M^2, m^2) = -i \int \frac{d^4p}{(2\pi)^d} \frac{1}{(p^2 - M^2)((p + q_1)^2 - M^2)((p + q_1 + q_2)^2 - m^2)}$$
$$= -\frac{1}{16\pi^2} \int_0^1 dx \int_0^{1-x} dy \frac{1}{M^2 - y(\Delta + t_1) + xy(t_1 - t_2) + y^2t_1}$$
$$= \frac{1}{(4\pi)^2(t_1 - t_2)} \left\{ Li_2 \left( \frac{1}{y_+(t_2)} \right) + Li_2 \left( \frac{1}{y_-(t_2)} \right) \right.$$  
$$- Li_2 \left( \frac{1}{y_+(t_1)} \right) - Li_2 \left( \frac{1}{y_-(t_2)} \right) \right\},$$

$$y_{\pm}(t) = \frac{1}{2t} \left\{ t + \Delta \pm \sqrt{\lambda(t, M^2, m^2)} \right\} \quad (B.6)$$

where $Li_2$ is the dilogarithm

$$Li_2(x) = -\int_0^1 \frac{dy}{y} \log(1 - xy). \quad (B.7)$$
C  Decomposition of the hadronic tensors $I^{\mu\nu}$

Here we consider the tensors

$$I^{\mu\nu} = \int dx e^{iqx+iy} < 0 \mid TV_{em}(x)I_{-i5}^{\nu}(y) \mid K^+(p) >, \quad I = V, A$$  \hspace{1cm} (C.1)

and detail their connection with the matrix element (1.2).

The general decomposition of $A^{\mu\nu}, V^{\mu\nu}$ in terms of Lorentz invariant amplitudes reads \cite{9, 11} for $q^2 \neq 0$

$$\frac{1}{\sqrt{2}} A^{\mu\nu} = -F_K \left\{ \frac{(2W^\mu + q^\mu)W^\nu}{M_K^2 - W^2} + g^{\mu\nu} \right\} + A_1(qW g^{\mu\nu} - W^\mu q^\nu) + A_2(q^2 g^{\mu\nu} - q^\mu q^\nu) + A_3(qW q^\mu - q^2 W^\mu)W^\nu$$  \hspace{1cm} (C.2)

and

$$\frac{1}{\sqrt{2}} V^{\mu\nu} = iV_1 \epsilon^{\mu\nu\alpha\beta} q_{\alpha} p_{\beta}$$  \hspace{1cm} (C.3)

where the form factors $A_i(q^2, W^2)$ and $V_1(q^2, W^2)$ are analytic functions of $q^2$ and $W^2$. $F_K^V(q^2)$ denotes the electromagnetic form factor of the kaon ($F_K^V(0) = 1$). $A^{\mu\nu}$ satisfies the Ward identity

$$q_{\mu} A^{\mu\nu} = -\sqrt{2}F_K P^\nu.$$  \hspace{1cm} (C.4)

In the process (1.1) the photon is real. As a consequence of this, only the two form factors $A_1(0, W^2)$ and $V_1(0, W^2)$ contribute. We set

$$A(W^2) = A_1(0, W^2) \quad V(W^2) = V_1(0, W^2)$$  \hspace{1cm} (C.5)

and obtain for the matrix element (1.2)

$$T = -iG_F/\sqrt{2}eV_{us} \epsilon_{\mu}^* \{ \sqrt{2}F_K l_1^{\mu} - (V^{\mu\nu} - A^{\mu\nu})l_\nu \} \rvert_{q^2=0},$$  \hspace{1cm} (C.6)

with

$$l^{\mu} = \bar{u}(p_{\nu})\gamma^{\mu}(1 - \gamma_5)v(p_l)$$

$$l_1^{\mu} = l^{\mu} + m_l \bar{u}(p_{\nu})(1 + \gamma_5)\frac{2p_l^{\mu} + q^{\mu}}{m_l^2 - (p_l + q)^2}v(p_l).$$  \hspace{1cm} (C.7)

Grouping terms into an IB and a SD piece gives (1.2, 1.3). As a consequence of (C.4), $T$ is invariant under the gauge transformation $\epsilon_{\mu} \rightarrow \epsilon_{\mu} + q_{\mu}$.

The amplitudes $A_1, A_2$ and $V_1$ are related to the corresponding quantities $F_A, R$ and $F_V$ used by the PDG \cite{3} by

$$-\sqrt{2}M_K(A_1, A_2, V_1) = (F_A, R, F_V).$$  \hspace{1cm} (C.8)
The last term in (C.2) is omitted in [3]. It contributes to processes with a virtual photon, \( K^\pm \rightarrow l^\pm \nu_l l'^\mp l'^+ l'^- \).

Finally, the relation to the notation used in [4, 5] is

\[
2(A \pm V)^2 = (a_k \pm v_k)^2 \quad [4]
\]

\[
\sqrt{2}(A, V) = (F_A, F_V) \quad [5].
\]  

(C.9)
D One-loop corrections to $K_{l4}$ form factors

In this appendix we give the expression of the unitarity corrections to the form factors $F, G$, and $R ([54],[55],[62])$.

$$U_F(s_\pi, t, u) = \Delta_0(s_\pi) + A_F(t) + B(t, u) , \quad (D.1)$$

with

$$\Delta_0(s_\pi) = \frac{1}{2} (2s_\pi - M_\pi^2) J^r_{\pi\pi}(s_\pi) + \frac{3s_\pi}{4} J^r_{KK}(s_\pi) + \frac{M_\pi^2}{2} J^r_{\eta\eta}(s_\pi) ,$$

$$A_F(t) = \frac{1}{16} \left[ (14M_K^2 + 14M_\pi^2 - 19t) J^r_{K\pi}(t) + (2M_K^2 + 2M_\pi^2 - 3t) J^r_{\eta K}(t) \right]$$

$$+ \frac{1}{8} \left[ (3M_K^2 - 7M_\pi^2 + 5t) K_{\pi\pi}(t) + (M_K^2 - 5M_\pi^2 + 3t) K_{\eta K}(t) \right]$$

$$- \frac{1}{4} \left[ 9(L_{K\pi}(t) + L_{\eta K}(t)) + (3M_K^2 - 3M_\pi^2 - 9t)(M_{K\pi}(t) + M_{\eta K}(t)) \right] ,$$

$$B(t, u) = -\frac{1}{2} (M_K^2 + M_\pi^2 - t) J^r_{K\pi}(t) - (t \leftrightarrow u). \quad (D.2)$$

The loop integrals $J^r_{\pi\pi}(s_\pi), \ldots$ which occur in these expressions are listed in appendix [8]. The functions $J^r_{PFQ}$ and $M^r_{PFQ}$ depend on the scale $\mu$ at which the loops are renormalized. The scale drops out in the expression for the full amplitude.

The imaginary part of $F^{-2}_\pi \Delta_0(s_\pi)$ contains the $I = 0$, $S$-wave $\pi\pi$ phase shift

$$\delta_0^0(s_\pi) = (32\pi F^2_\pi)^{-1} (2s_\pi - M_\pi^2) \sigma_\pi + O(E^4) , \quad (D.3)$$

as well as contributions from $K\bar{K}$ and $\eta\eta$ intermediate states. The functions $A_F(t)$ and $B(t, u)$ are real in the physical region.

$$U_G(s_\pi, t, u) = \Delta_1(s_\pi) + A_G(t) + B(t, u) , \quad (D.4)$$

with

$$\Delta_1(s_\pi) = 2s_\pi \left\{ M^r_{\pi\pi}(s_\pi) + \frac{1}{2} M^r_{KK}(s_\pi) \right\} ,$$

$$A_G(t) = \frac{1}{16} \left[ (2M_K^2 + 2M_\pi^2 + 3t) J^r_{K\pi}(t) - (2M_K^2 + 2M_\pi^2 - 3t) J^r_{\eta K}(t) \right]$$

$$+ \frac{1}{8} \left[ (-3M_K^2 + 7M_\pi^2 - 5t) K_{\pi\pi}(t) + (-M_K^2 + 5M_\pi^2 - 3t) K_{\eta K}(t) \right]$$

$$- \frac{3}{4} \left[ L_{K\pi}(t) + L_{\eta K}(t) - (M_K^2 - M_\pi^2 + t)(M_{K\pi}(t) + M_{\eta K}(t)) \right] . \quad (D.5)$$

The imaginary part of $F^{-2}_\pi \Delta_1(s_\pi)$ contains the $I = 1$, $P$-wave phase shift

$$\delta_1^1(s_\pi) = (96\pi F^2_\pi)^{-1} s_\pi \sigma_\pi^3 + O(E^4) . \quad (D.6)$$
as well as contributions from $K\bar{K}$ intermediate states. The function $A_G$ is real in the physical region.

The unitarity corrections $U_Z, U_Q$ in the form factor $R$ in (5.58) are

$$
U_Z = s_\pi \Delta_0(s_\pi) + \nu \Delta_1(s_\pi) - \frac{4}{9} M_K^2 M_\pi^2 J_{\eta \eta}^r(s_\pi)
+ \frac{1}{32} \left[ 11(s_\pi - \nu)^2 - 20\Sigma(s_\pi - \nu) + 12\Sigma^2 \right] J_{K\pi}^r(t)
+ \frac{1}{96} [3(s_\pi - \nu) - 2\Sigma]^2] J_{\eta \eta K}^r(t)
+ \frac{1}{4} (s_\pi + \nu)^2 J_{K\pi}^r(u)
+ \frac{1}{4} (M_K^2 - M_\pi^2) [5(s_\pi - \nu) - 6\Sigma] K_{K\pi}(t)
+ \frac{1}{4} (M_K^2 - M_\pi^2) [3(s_\pi - \nu) - 2\Sigma] K_{\eta \eta K}(t)
+ \frac{3}{8} \left[ 2s_\pi(\nu + 4\Sigma) - 3s_\pi^2 + \nu^2 - 16M_\pi^2 M_K^2 \right] \left[ M_{K\pi}^r(t) + M_{\eta \eta K}^r(t) \right]
- \frac{3}{4} (3s_\pi + \nu - 2\Sigma)(L_{\eta \eta K}(t) + L_{K\pi}(t)) ,
$$

$$
U_Q = \Delta_0(s_\pi) + \frac{M_K^2 - s_l}{32} \left\{ 11 J_{K\pi}^r(t) + 8 J_{\eta K}^r(u) + 3 J_{\eta \eta K}^r(t) \right\}
- \frac{1}{8} (5s_\pi - \nu) + 5(M_K^2 - s_l) - 6\Sigma) K_{K\pi}(t)
- \frac{1}{8} (3(s_\pi - \nu) + 3(M_K^2 - s_l) - 2\Sigma) K_{\eta \eta K}(t)
- \frac{9}{4} (L_{\eta \eta K}(t) + L_{K\pi}(t))
+ \frac{3}{8} (4(\nu + 2M_\pi^2) - 3(M_K^2 - s_l))(M_{K\pi}^r(t) + M_{\eta \eta K}^r(t))
$$

with

$$
\Sigma = M_K^2 + M_\pi^2 .
$$
