Abstract. We present the most up-to-date and complete multi-wavelength correlation analysis on luminosity properties of TeV BL Lacs. Correlation function (power law or linear) parameters are calculated based on linear regression method. Using the lower energy luminosities of a sample of 182 non-TeV BL Lacs and the generated functions, minimum level of VHE gamma-ray emission was calculated for each non-TeV BL Lac. This multi wavelength prediction method gives us a list of best candidates to be observed with current generation of Imaging Air Cherenkov Telescopes.

Keywords. BL Lacs, VHE gamma-ray

1. Introduction

The majority of extragalactic objects detected in Very High Energy (VHE) \(\gamma\)-ray band (\(>100\) GeV) are from rare type of radio-loud Active Galactic Nuclei (AGN) called BL Lacs. As a subclass of blazars, BL Lacs’ jets are nearly aligned to the observer’s line of sight. As bright distant objects, VHE \(\gamma\)-ray emitting (TeV) BL Lacs can be used to study the universe between us and BL Lacs. The observed properties of BL Lacs in VHE \(\gamma\)-rays band are measured using targeted observation by Imaging Air Cherenkov Telescopes (IACTs). Only 57 BL Lacs are detected in VHE \(\gamma\)-rays band. Therefore, IACTs are expected to discover many BL Lacs in VHE gamma-rays band. But due to the restrictions on current technology a prediction method based on the lower energy data is demanding. We constructed a prediction method based on the cross bands luminosity of TeV BL Lacs.

2. Samples, Data and methodology

Radio (4.85 GHz), Optical (R-band), X-ray (2-10 keV) and Gamma-ray (1-100 GeV) data are collected from literature and databases for TeV (\(#47\)) and non-TeV (\(#182\)) BL Lacs. VHE \(\gamma\)-ray flux (\(>200\) GeV) are collected for TeV sample by dividing this sample to multiple (Group A) and single detected (Group B). Five VHE \(\gamma\)-ray data sets are formed based on different states of group A (high state and low state), group B and combination of group B with each state of group A. Figure 1 illustrate the distribution of TeV sample in different Luminosity-Luminosity planes in logarithmic scale. Figure 2 illustrates the approach to check the existence of correlation and calculating the best fitted model parameters. The lower energy band luminosities of non-TeV BL Lacs are used as variable input for the prediction functions. We calculate at least 4 levels of VHE gamma-ray luminosity for each non-TeV BL Lac. The non-TeV BL Lacs with highest predicted VHE gamma-ray flux are selected as the promising TeV candidates.
Figure 1. Luminosity in the VHE γ-ray band versus the luminosity in radio (a), optical (b), X-ray (c) and γ-ray (d) bands in logarithmic scale. All the axis are in [erg/s] unit. The different symbols represent the data of different groups (see text): Low state group A (circle), High state group A (triangle) and group B (cross). The correlation functions of the low state of group A is shown with dashed line. The solid/dot-dashed lines represent the correlation functions of the combined data sets of group B and low/high state of group A.

3. Results and Conclusions

There are 7 significant correlations between lower energy bands and TeV band. All the significant correlations can be described better with power law model. We build our prediction functions based on these correlations. The lower energy band luminosities of non-TeV BL Lacs are used as variable input for the prediction functions. At least 4 levels of VHE gamma-ray luminosity are calculated for each non-TeV BL Lac. The non-TeV BL Lacs with highest predicted VHE gamma-ray flux are selected as the promising TeV candidates and listed in table 1.
