ARTICLE INFO

Keywords: Nutritional quality Food choice motives Lockdown COVID-19

ABSTRACT

To limit the transmission of COVID-19, nationwide lockdown was imposed in France between March, 17th and May 10th, 2020. This disruption in individuals’ daily routines likely altered food consumption habits. We examined how changes in food choice motives related to changes in nutritional quality during the lockdown compared to before. A convenience sample of 938 French adults completed online questionnaires on the Qualtrics platform at the end of April 2020. Participants were retrospectively asked about their food choice motives and food consumption during the month before and in the first month of the lockdown. The importance of nine food choice motives was assessed: health, convenience, sensory appeal, natural content, ethical concern, weight control, mood, familiarity, and price, scoring from 1 to 4. Food intakes were recorded using a food frequency questionnaire including 110 foods, 12 non-alcoholic beverages and 4 alcoholic beverages. Adherence to the French dietary recommendations before and during the lockdown was estimated using the simplified PNNS-GS2, scoring from −17 to 11.5. The nutritional quality of diet was lower during the lockdown compared to before (−0.32, SD 2.28, p < 0.001). Food choice motives significantly changed and an increase in the importance of weight control was associated with increased nutritional quality (β = 0.89, p < 0.001, partial η² = 0.032), whereas an increase in the importance of mood was associated with decreased nutritional quality (β = −0.43, p = 0.021, partial η² = 0.006). The lockdown period in France was related to a decrease in nutritional quality of diet on average, which could be partly explained by changes in food choice motives. The lockdown was indeed related to modification of food choice motives, notably with an increase of mood as a food choice motive for 48% of the participants, but also with an increase of health (26%), ethical concern (21%) and natural content (19%) suggesting a growing awareness of the importance of sustainable food choices in some participants.

1. Introduction

The world is currently facing the COVID-19 pandemic. To avoid fast-growing transmission of the virus, governmental authorities have had to impose nationwide lockdowns. In France, between March 17th and May 10th, 2020, most of the population was asked to stay home. In order to limit drastically any human contact, the French were allowed to leave their home only for grocery shopping, medical care, legal obligations and physical activity within a 1 km radius; except for workers from essential sectors (e.g., healthcare, food factories and shops). During this period, all businesses that sold food remained open to the public. However, major disruptions in daily routines caused by the lockdown (e. g., home-working, restaurant closures) were likely to alter food consumption habits in the French population. Moreover, closed borders led to changes in the distribution and availability of food products (Morel, Stroobants, Bran, Iwaniuk, & Hauteville, 2020; Oxfam France, 2020).

A large part of humans’ eating behaviours are habits, i.e., automatic associations between specific context cues and responses, which have history of repetition and reward. Habits form as people pursue goals by repeating the same responses in given contexts, and become automatic and hard to change (Wood & Runger, 2016). Because food choices are performed every day and usually in the same context, they likely result from a habitual response; notably, food choices have been shown to be very stable in adulthood (Borland, Robinson, Crozier, & Inskip, 2008; Hu et al., 1999; Khani, Ye, Terry, & Wolk, 2004; Weismayer, Anderson, 2008).
& Wolk, 2006). However, when people are undergoing changes in their environment, their habits are vulnerable to change as they engage in a new non-automatic process of decision making (Verplanken & Wood, 2006). We thus hypothesised that the unusual lockdown period may have caused discontinuities in food choice habits.

In a constructionist perspective, food choice decisions result from one’s personal food values that are shaped by life course events, personal and social factors (Furst, Connors, Bisogni, Sobal, & Falk, 1996; Sobal & Bisogni, 2009). Food values are computed by integrating a set of attributes (food choice motives) based on their importance or salience for an individual at the point of choice (Rangel, 2013). A change in food choice motives may thus lead to a change in food choice decisions. The most important food choice motives have been shown to be taste, cost, nutrition and convenience with a large interindividual variability (Glanz, Basil, Maibach, Goldberg, & Snyder, 1998). We hypothesised that people engaging in a new process of food choice decision making during the lockdown period may have caused changes in food choice motives associated with changes in food choice habits, resulting in modification of the nutritional quality of diet.

The present study aimed to examine the extent of changes in food choice motives during the lockdown and how it related to changes in nutritional quality of diet. We hypothesised that food choice motives and nutritional quality of diet changed during the first month of lockdown (from March 17th to April 16th, 2020) compared to the month just before the lockdown (from February 17th to March 16th, 2020). We also hypothesised that changes in food choice motives were associated with changes in nutritional quality. Because poor nutritional quality diet is one of the main risk factors for non-communicable diseases (Afshin et al., 2019), it is of importance to examine the effect of the lockdown on nutritional quality to help anticipating health consequences at a population level. Moreover, this unique nationwide disruption in daily life gives the opportunity to investigate how changes in food choice motives may influence the nutritional quality of diet at an individual level. The results may inform future public health actions that aim to tackling diet related non-communicable diseases by identifying which food choice motives changes may increase or decrease the nutritional quality of diet.

2. Methods

2.1. Design and data collection

This was a cross-sectional, pre-registered online experiment conducted in Qualtrics survey platform (www.qualtrics.com). Participants were recruited by emailing individuals from a population registered in the Chemosens Platform’s PanelSens database at Centre des Sciences du Goût et de l’Alimentation (Dijon). This database was declared to the relevant authority (Commission Nationale Informatique et Libertés; CNIL; n’1,148,039). Eligible participants were aged over 18, had been residing in France at least since February 17th, 2020 (i.e., one month before the lockdown) and had access to a computer or tablet with an internet connection. Eligible participants who completed the study received compensation in return for their participation (15€ Amazon voucher). The study was approved by the ethical evaluation committee for research of INSERM (reference: n’20–683, delivered on April 27th, 2020). All participants were informed that the purpose of the study was to investigate food choices during the lockdown and provided consent for their participation. Data were collected on April 30th and May 1st, 2020. Three attention check questions (e.g., ‘How many times have you visited the planet Mars?’) were included in various parts of the questionnaire.

2.2. Measures

2.2.1. Participants’ characteristics

Participants’ characteristics assessment included demographic questions (age, gender, employment status, highest educational qualification, professional situation during the lockdown, living area, type of housing, household composition, financial situation) and food-related behaviours questions (out-of-home eating habits before the lockdown, grocery shopping frequency and time spent cooking during the lockdown, changes in eating habits during the lockdown, dietary restrictions, dieting status, weight and height at the time of the study). Participants also answered questions about their consumption of organic and local food products (not reported here). As participants were recruited during the COVID-19 pandemic, they were asked if they suspected having or having had COVID-19 and how worried they were about their health. We also asked for current levels of stress, depression, and loneliness (3 individual items) on a continuous scale from 0 to 100.

2.2.2. Food choice motives

Food choice motives were assessed using a French version of the Food Choice Questionnaire developed in English by (Steptoe, Pollard, & Wardle, 1995) and adapted by (Cottet, Ferrandi, Lichtlé, & Planchon, 2017). The French version included 24 items and nine subscales: health (3 items), convenience (3 items), sensory appeal (3 items), natural content (3 items), ethical concern (2 items), weight control (3 items), mood (3 items), familiarity (2 items), and price (2 items). See Additional file – section 1 for the items in French and in English. Instructions were adapted to assess food choice motives during the month before the lockdown and during the first month of the lockdown simultaneously. For each subscale, two scores were computed by averaging ratings for individual items before and during the lockdown, respectively. The scores ranged from 1 to 4: 1 = Not at all important; 2 = A little important; 3 = Moderately important; 4 = Very important. Δ motives were calculated as the difference of the score for each of the nine subscales during and before the lockdown. Δ motives > 0 indicated higher importance of the motives during the lockdown compared to before.

2.2.3. Food consumption and dietary nutritional quality

Food consumption was retrospectively assessed for the month before the lockdown and the first month of the lockdown simultaneously using a validated food frequency questionnaire including 110 foods, 12 non-alcoholic drinks and 4 alcoholic drinks with frequency assessed by a 6-item scale from “Never” to “Several times a day” (Kadawathagedara et al., 2017). Usual portion sizes before and during the lockdown were estimated with photos for different food types on a 5-level scale, derived from the SU.VI.MAX portion book (Herberg, Deheeger, & Preziosi, 2002), for 72 commonly eaten food items, and by the intermediate portion size for the 38 remaining food items. Participants were also asked the size of the glass or cup they used before and during the lockdown for each non-alcoholic beverage and standard servings were used to estimate alcoholic beverage amounts. Consumption frequency of each item before and during the lockdown was transformed into daily frequency, and daily intake was calculated by multiplying the daily frequency by the estimated portion size. Individual nutrients intakes were calculated before and during the lockdown by multiplying the daily intake of each food item by its nutritional values from the SU.VI.MAX nutrient composition database (Herberg, 2006).

Adherence to the French dietary recommendations was evaluated during the month before the lockdown and during the first month of the lockdown using the simplified PNNS-GS2 (sPNNS-GS2), an index previously designed to reflect the 2017 French main dietary recommendations (Chaltiel et al., 2019). The sPNNS-GS2 builds on the distinction between health-promoting food groups (less healthy food groups which consumption should be limited, carrying a negative score, i.e., red meat, processed meat, sugary foods, sweet-tasting beverages, alcoholic beverages, salt) and bonus components (healthier food groups carrying a positive score, i.e., fruits and vegetables, nuts, legumes, whole-grain food, milk and dairy products, fish and seafood). The sPNNS-GS2 calculation has been previously described by Chaltiel et al., 2019. A weight for each component is defined according to the level of evidence of the association between food groups consumption and health status. sPNNS-GS2
were conducted to examine whether the pattern of results from the main Δ multiple linear regression including the nine who declared that they did not make any noticeable change in their diet model differed: 1/ including age, gender, highest educational level and week, infected by the corona virus vs. not infected. We then examined having meal out of home at least four times a week vs. less than 4 times a day for women, and < 4000 kcal/day for men (Banna, McCrory, Fialkowski, day for women, and < 4000 kcal/day for men (Banna, McCrory, Fialkowski, & Boushey, 2017; Willett, 2013).

For descriptive purposes, we compared food choice motives scores and sPNNS-GS2 components before and during the lockdown using paired T-tests. As exploratory analyses, we also examined whether changes in food choice motives or nutritional quality during the lockdown compared to before differed across population subgroups using one-way ANOVAs: people who are younger vs. older, male vs. female, normal-weight vs. overweight, lower vs. higher educational level, facing financial difficulties vs. people who were not, living alone during the lockdown vs. with others, living in a city vs. in the countryside, usually having meal out of home at least four times a week vs. less than 4 times a week, infected by the corona virus vs. not infected. We then examined the influence of changes in food choice motives during and before the lockdown on the difference in nutritional quality of diet by running a multiple linear regression including the nine Δ motives as predictors and Δ quality as the dependant variable (main model). Sensitivity analyses were conducted to examine whether the pattern of results from the main model differed: 1/ including age, gender, highest educational level and declared BMI as covariates (adjusted model), 2/ excluding participants who declared that they did not make any noticeable change in their diet during the lockdown, 3/ excluding participants who declared that they often did not find in store what they wanted to buy during the lockdown, as change in diet quality could be due more to external constraints than to personal motives, 4/ excluding participants who declared that they went to work as normal during the lockdown. As an additional exploratory analysis, we also adjusted the main model for the variables with significant effects on Δ motives or Δ quality in the exploratory one-way ANOVAs.

All statistical analyses were performed using SAS version 9.3 (SAS Institute, Inc. 2012 SAS® 9.3, Cary, NC). The level of significance was set at p < 0.05 applying Bonferroni correction for multiple comparisons where appropriate.

2.4. Statistical analyses

Hypotheses were specified before the data were collected and we followed an analytic plan that was pre-registered before data analysis (https://osf.io/gwfbv/). Only participants who completed the study were included in the analyses. Participants who failed at least one attention check were excluded. We analysed data from participants who reported plausible energy intake, i.e. > 500 kcal/day and < 3500 kcal/day for women, and > 800 kcal/day and < 4000 kcal/day for men (Banna, McCrory, Fialkowski, & Boushey, 2017; Willett, 2013).

3. Results

3.1. Participants

A total of 1353 participants consented to participate. Participants who were not eligible (n = 110), did not complete the study (n = 121), failed at least one attention check (n = 84) or reported implausible energy intake (n = 100) were excluded and data from 938 participants were analysed. Participants’ characteristics are presented Table 1. Eighteen participants declared that they suspected having COVID-19 when they completed the study and 59 declared that they suspected having had COVID-19 before. Six hundred participants (64%) declared being slightly to very worried about their health. On average levels of stress, depression, and loneliness were 26 (SD 28), 23 (SD 25), and 34 (SD 28) respectively on a scale from 0 to 100.

3.2. Food choice motives and nutritional quality of diet before and during the lockdown

Food choice motives changed significantly during the lockdown compared to before (Table 2). In particular, 48% of the participants declared that mood was more important in their food choices during the lockdown compared to before and 48% declared that convenience was less important. Health and weight control were more important during the lockdown compared to before and 26% of the participants, respectively.

On average, the participants consumed 1700 kcal/day (SD 596) during the month before the lockdown and 1935 kcal/day (SD 656) during the first month of lockdown and this increase was statistically significant (paired t-test: t(937) = 13.57, p < 0.001). Overall, the nutritional quality of diet significantly decreased during the first month of the lockdown compared to the month before (Table 3). Despite an increase in fruit and vegetables, pulses, fish and seafood consumption, the sharp increase in processed meat, sweet-tasting beverages and alcoholic beverages consumption negatively affected the sPNNS-GS2.

We explored whether changes in food choice motives and nutritional quality during the lockdown compared to before differed across population subgroups and found relatively few significant differences (see Additional file – section 3).

When examining the influence of changes in food choice motives on changes of the nutritional quality of diet during the lockdown compared to before, we found that increased importance of weight control motives was associated with increased nutritional quality and that increased importance of mood motives was associated with decreased nutritional quality in both raw and adjusted multiple linear regressions (Table 4). Changes in other food choice motives were not associated with changes in the nutritional quality of diet. In the other three multiple linear regressions testing the influence of changes in food choice motives on changes of the nutritional quality conducted as sensitivity analyses (i.e., excluding participants who declared that they did not have any noticeable change in their diet during the lockdown, excluding participants who declared that they often did not find in store what they wanted to buy during the lockdown, excluding participants who declared that they went to work as normal during the lockdown), Δ weight control and Δ mood remained significant or marginally significant predictors of Δ quality (see Additional file – section 4). In addition, the exploratory adjusted model, including the variables from

2.5. Sample size calculation

We aimed to recruit a sample size of 1000 participants to detect small differences in food choice motives scores and sPNNS-GS2 before and during the lockdown using paired t-tests (d = 0.1) and small effects of Δ motives on Δ quality in a multiple linear regression including nine predictors (R² = 0.016) at power 0.80 and level of significance 0.05 (GPower 3.1).
the lockdown were observed with an increase in the importance of mood, weight control, health, ethical concern, natural content and sensory appeal, and a significant decrease in the importance of convenience, familiarity, and price. The participants reported a 14% increase in energy intake and a decrease in nutritional quality of their diet during the lockdown compared to before. An increase in the importance of weight control during the lockdown was associated with increased nutritional quality, whereas an increase in the importance of mood was associated with decreased nutritional quality. Changes in the importance of other food choice motives were not associated with changes in nutritional quality of diet.

Increase in energy intake and unhealthier dietary patterns during the lockdown compared to before were also described in a study conducted among 37,252 French adults from the web-based NutriNet-Santé cohort (Descassaux-Tanguy et al., 2020). The authors found an energy intake of 1942 kcal/day during the lockdown, which is similar to the reported energy intake reported during the lockdown in the present study (1935 kcal/day on average). The authors highlighted weight gain for 35% of the sample and increased consumption of sweets, biscuits, and cakes. Consistently, despite the fact that the participants of the present study increased their intake of fruit and vegetables, pulses, fish and seafood, they also increased their consumption of processed meat, sugary foods, sweet-tasting beverages and alcoholic beverages leading to a decrease in the nutritional quality of their diet on average. These changes in food consumption patterns echo studies showing increased snacking during the lockdown (Descassaux-Tanguy et al., 2020; Sanchez & Moreno, 2020), as fatty-sweet products and sweet-tasting beverages (including fruit juices) are usually consumed during snacking episodes by French adults (Si Hassen et al., 2018). In addition, a survey on 3000 French adults reported that 42% declared having pre-meal drinks (“aperitif”) more often during than before the lockdown (Darwin Nutrition & IFOP, 2020). Pre-meal drinks are usually the first part of a meal, opening a social eating time and are often accompanied by finger foods (Danesi, 2018). The deterioration of nutritional quality during the lockdown may be partly due to increased number of social and festive eating occasions within the home, associated with consumption of low-nutritional-quality foods (e.g., sweet-tasting beverages and alcoholic beverages, processed meat, sugary foods). Changes in health, ethical concern, natural content, sensory appeal, and price food choice motives during the lockdown are in line with the results of a survey conducted among a representative sample of 1005 French adults where the participants declared changes in their perception of the ecological (49%), social (47%) and economical (57%) values of the food during the lockdown (YouGov, 2020). The decrease in the importance of convenience for 48% of our sample mirrored that 83% declared that they increased their time spent cooking during the lockdown. Collectively, these changes in food choice motives may reflect a growing awareness of the importance of the sustainability of food choices where preserving health and pleasure from eating, protecting the environment and guaranteeing decent wages to farmers are equally important (FAO & WHO, 2019).

Increase in the importance of mood (48% of the participants) and weight control (29% of the participants) food choice motives were prominent and associated with opposite changes in nutritional quality of diet. Stress, feeling of emptiness and boredom management by eating were common behaviours in the French population during the lockdown with 63%, 63%, and 57% prevalence in a 1092 sample of French adults, respectively (Cherikh et al., 2020). Occasional emotion regulation by eating was associated with the consumption of sweet foods (De Lauson et al., 2004; Macht & Simmons, 2011) which may explain the negative relationship between changes in mood food choice motive and nutritional quality of diet. On the contrary, increased importance of weight control led to increased nutritional quality, suggesting that participants engaging in weight management behaviour successfully stuck with their goal by managing their food intake during the first month of the lockdown. In line with our results, a study investigating eating behaviour

### Discussion

To our knowledge, this is the first study that investigated changes in food choice motives associated with nutritional changes during the lockdown in France. Significant changes in food choice motives during exploratory analyses for which we found differences in Δ motives or Δ importance at alpha level = 0.05, also led to similar results (see Additional file – section 4).

#### Table 1
Participants’ characteristics, n = 938.

| Age, years, mean (SD) | 38.7 (11.6) |
|-----------------------|------------|
| Gender, female, n (%) | 736 (78.5) |
| Employment status, n (%) | 726 (77.4) |
| Full or part-time       | Student    |
|                        | 66 (7.1)   |
| Retired                | 48 (5.1)   |
| Looking for a job      | 65 (6.9)   |
| Looking after home     | 12 (1.3)   |

Table 3

Comparison of the nutritional quality of diet before and during the lockdown.

| Recommendation | Before lockdown mean (SD) | During lockdown mean (SD) | p-value<sup>a</sup> |
|----------------|---------------------------|---------------------------|-------------------|
| pNNS-GS2<sup>b</sup> | 1.2 (2.5) | 0.8 (2.8) | <.001 |

<sup>a</sup> Paired t-tests, Bonferroni corrected alpha level: 0.004.
<sup>b</sup> Without added fat component, range from ~17 to 11.5.

Nutrient intakes were higher during the lockdown in 2364 UK adults showed that 35% of the participants declared eating a more healthy and balanced diet during the lockdown compared to before (Robinson et al., 2020). It is worth noticing that in the present study increased importance of health as a food choice motive was not significantly correlated with increased nutritional quality; whereas people more motivated by health were reported to adopt healthier diet than people less motivated by health (Konttinen, Sarlio-Lähteenkorva, Silventoinen, Männistö, & Haukkala, 2012; Naughton, McCarthy, & McCarthy, 2015). Moreover, we would have expected an increase in nutritional quality when price became less important because of the positive association between price and nutritional quality across individual food items (Andrieu, Darmon, & Drewnowski, 2006; Marty et al., 2015; Rehm, Monsivais, & Drewnowski, 2011), but this is not supported by these data. Similarly, we would have expected an increase in nutritional quality when convenience became less important because the degree of food processing and convenience were shown to be negatively associated with nutritional quality (Martinez Steele, Popkin, Swinburn, & Monteiro, 2017; Poti, Mendez, Ng, & Popkin, 2015). Our results suggest that choosing more expensive and less convenient foods (i.e., requiring more effort and time to prepare) did not necessarily translate into better nutritional quality of diet. Overall, the difference in the measured food choice motives only explained 5.7% of the variance of the change in the nutritional quality during compared to before the lockdown. Nutritional quality is multidimensional by nature; food choices are complex decisions and various other variables may have influenced what people chose to eat and the resulting nutritional quality of their diet during the lockdown, for instance the availability of food products.

5. Strengths and limitations

We were able to collect detailed information about food consumption during the month before the lockdown and during the first month of the lockdown in a large sample of French adults. Our study was timely as the data were collected two weeks after the end of the first month of the lockdown. However, the participants retrospectively reported their food consumption which is a clear limitation of this study. We could not anticipate the lockdown and organise a measurement point before the lockdown. Participants were asked to report simultaneously for each food item their consumption before and during the lockdown which made it easier reporting differences in consumption frequency, even if a recall bias could have affected the responses for the period before the...
lockdown. In other respects, due to this exceptional situation, we compared food consumption in March (before the lockdown, end of winter) and in April (during the lockdown, beginning of spring). We could have expected a season effect in our data, with an improvement of the nutritional quality of diet in April compared to March due to increased availability of fresh fruit and vegetables, although access to fresh product may have been limited by the lockdown (Oxfam France, 2020). Finally, due to unexpectedly high numbers of participants who failed an attention check or reported implausible energy intake (16.4% of the eligible participants who completed the study), we did not reach the sample size of 1000 participants we aimed for. However, a sample size of 938 participants still allowed to detect small effects of Δ motives on Δ quality in a multiple linear regression including nine predictors (Frieden, 2010). A secondary objective of this research of INSERM (reference: n = 683, delivered on April 27th, 2020) was to compare consumption of organic and locally produced food before and during the lockdown and to understand and directly accessible by consumers at the point of choice should be prioritised, e.g., the front-of-pack nutrition label Nutriscore (Egnell et al., 2018).

### 7. Conclusion

The lockdown period in France was related to a decrease in the nutritional quality of diet on average which could be partly explained by changes in food choice motives. The lockdown was indeed related to modification of food choice motives in this sample, notably with an increase of mood as a food choice motive. Moreover, the importance of place-convenience and price motives decreased whilst the importance of health, natural content and ethnic motives increased, suggesting a growing awareness of the importance of sustainable food choices.

### Ethical statement

The study was approved by the ethical evaluation committee for research of INSERM (reference: n = 20–683, delivered on April 27th, 2020). All participants were informed that the purpose of the study was to investigate food choices during the lockdown and provided consent for their participation.

### Acknowledgments

We thank the ChemoSens platform for the help with data collection, in particular C. Martin and F. Durey; and V. Feyen for her help with participant management. This work was supported by grants from ANR (ANR-15-CE21-0014, PUNCH grant to SN), the Conseil Régional Bourgogne, Franche-Comté (PARI grant) and the FEDER (European Funding for Regional Economic Development). The funders had no role in planning, conducting, or interpreting the study.

### Appendix A. Supplementary data

Supplementary data to this article can be found online at https://doi.org/10.1016/j.appet.2020.105005.

### Author contributions

LM and SN designed the study and were responsible for data collection. LM and ML analysed the data. BLG developed the food frequency questionnaire and assisted in data analyses. LM was responsible for Regional Economic Development. The funders had no role in planning, conducting, or interpreting the study.

### Table 4

| Δ motives | β estimate | p-value | partial η² | Δ motives | β estimate | p-value | partial η² |
|-----------|------------|---------|------------|-----------|------------|---------|------------|
| Δ Weight control | 0.09       | <.001   | 0.032      | Δ Weight control | 0.24       | <.001   | 0.043      |
| Δ Mood    | −.43       | 0.021   | 0.006      | Δ Mood    | −.42       | 0.035   | 0.006      |
| Δ Health  | 0.31       | 0.227   | 0.002      | Δ Health  | 0.29       | 0.285   | 0.002      |
| Δ Sensory appeal | 0.21   | 0.491   | 0.001      | Δ Sensory appeal | 0.27   | 0.418   | 0.002      |
| Δ Familiarity | −.15   | 0.312   | 0.001      | Δ Familiarity | −.14   | 0.391   | 0.001      |
| Δ Price   | −.11       | 0.427   | 0.001      | Δ Price   | −.20       | 0.197   | 0.002      |
| Δ Ethical concern | −.09 | 0.621   | <.001      | Δ Ethical concern | −.30   | 0.155   | 0.003      |
| Δ Natural content | −.07 | 0.811   | <.001      | Δ Natural content | 0.17   | 0.573   | <.001      |
| Δ Convenience | 0.01 | 0.895   | <.001      | Δ Convenience | 0.04   | 0.765   | <.001      |

Variance inflation factor: Δ Health (1.72), Δ Convenience (1.23), Δ Sensory appeal (1.17), Δ Natural content (1.80), Δ Ethical concern (1.40), Δ Weight control (1.37), Δ Mood (1.08), Δ Familiarity (1.18), Δ Price (1.08). Δ quality is the difference in sPNNS-GS2 score during the lockdown compared to before. Δ quality > 0 indicated better nutritional quality during the lockdown compared to before. Δ motives > 0 indicated higher importance of the motives during the lockdown compared to before.

* Control variables: age, gender, BMI, highest educational qualification.
