Abstract: The main aim of this paper is to investigate the combination synchronization phenomena of various fractional-order systems using the scaling matrix. For this purpose, the combination synchronization is performed by considering two drive systems and one response system. We show that the combination synchronization phenomenon is achieved theoretically. Moreover, numerical simulations are carried out to confirm and validate the obtained theoretical results.

Keywords: fractional-order systems; Caputo–Hadamard derivative; combination synchronization

1. Introduction

Fractional calculus is an old topic, going back to Riemann–Liouville, Leibniz, and Grünwald–Letnikov, where derivatives and integrals are considered of a real or complex order [1,2]. In the last three decades, fractional calculus has gained a lot of interest due to its application in various scientific fields [3–6]. The fractional derivative is considered an excellent tool for explaining different processes with memory and anomalous diffusion problems compared to the classical derivative [7]. In the literature, there are many famous definitions of fractional derivatives, such as Caputo, Riemann–Liouville, Katugampola, and Hadamard, that have been described and used in many scientific applications [2,8,9]. Nowadays, other fractional definitions have become valuable because of their applications and background. For instance, the Caputo–Hadamard fractional-order derivative is a modified version of the Hadamard fractional-order derivative. More details, including the analysis and application of the Caputo–Hadamard fractional derivative, can be found in [10–12]. Furthermore, new results for complicated fractional Caputo–Hadamard systems using various theoretical techniques are presented in [13,14].

Synchronization is a procedure in which two or more systems react with each other, leading to a joint development in some of their dynamic characteristics. These systems are able to adjust their pace and exhibit the same behavior over time. The concept of synchronization in chaotic systems was proposed by Pekora and Carol [15]. Thereafter, the phenomena of synchronization gained a lot of attention from numerous researchers. Due to the growing interest in studying the synchronization phenomena for chaotic dynamical systems, many types of synchronization have been discovered in the literature [16–20].

Recently, Runzi et al. [21] presented a new type of synchronization called combination synchronization. This type of synchronization consists of one response system and two drive systems. Combination synchronization has been applied to widespread applications, especially for various chaotic systems [7,22,23]. Moreover, the combination synchronization phenomenon has also been studied for fractional dynamical systems [24–26].

This paper is structured in the following manner: In Section 2, we provide some preliminaries for fractional calculus. Section 3 introduces the main idea of the combination
synchronization of fractional-order systems given in this paper and shows that the combination synchronization phenomena are theoretically achieved. To validate the theoretical analysis, numerical simulations are provided in Section 4. Finally, some conclusions are presented in Section 5.

2. Preliminaries

In this section, we reviewed some useful definitions that served as the basis for our present work.

The Caputo fractional derivative of $h$ of order $\varsigma$ was provided by:

$$\mathcal{C} \mathcal{D}_{t_0}^{\varsigma} h(t) = \mathcal{D}_{t_0}^{\varsigma} [h(t) - h(t_0)],$$

where $\mathcal{D}_{t_0}^{\varsigma} h(t)$ denotes the Riemann–Liouville fractional derivative:

$$\mathcal{D}_{t_0}^{\varsigma} h(t) = \frac{1}{\Gamma(1-\varsigma)} \frac{d}{dt} \int_{t_0}^{t} (t-v)^{-\varsigma} h(v) dv.$$

If $h$ was absolutely continuous, then the Caputo fractional derivative could be written in an equivalent form as follows:

$$\mathcal{C} \mathcal{D}_{t_0}^{\varsigma} h(t) = \frac{1}{\Gamma(1-\varsigma)} \int_{t_0}^{t} (t-v)^{-\varsigma} h'(v) dv.$$

The Hadamard fractional derivative was defined by:

$$\mathcal{H} \mathcal{D}_{t_0}^{\varsigma} h(t) = \frac{1}{\Gamma(1-\varsigma)} \frac{d}{dt} \int_{t_0}^{t} \left( \log \frac{t}{v} \right)^{-\varsigma} h(v) \frac{dv}{v}.$$

Let $\varsigma > 0$, and if we considered $h(t) = (t-t_0)^{\varsigma}$ and $g(t) = \left( \log \frac{t}{t_0} \right)^{\varsigma}$, then:

$$\mathcal{C} \mathcal{D}_{t_0}^{\varsigma} h(t) = \frac{\Gamma(\varsigma+1)}{\Gamma(\varsigma+1-\varsigma)} (t-t_0)^{\varsigma-\varsigma} \quad \text{and} \quad \mathcal{H} \mathcal{D}_{t_0}^{\varsigma} g(t) = \frac{\Gamma(\varsigma+1)}{\Gamma(\varsigma+1-\varsigma)} \left( \log \frac{t}{t_0} \right)^{\varsigma-\varsigma}.$$

The Caputo–Hadamard fractional derivative of order $\varsigma$ is one natural consequence of these concepts.

Definition 1 ([8]). The Caputo–Hadamard derivative of fractional-order $\varsigma \in (0, 1)$ for a function $h : [t_0, \infty) \to \mathbb{R}$ was defined as:

$$\mathcal{C H} \mathcal{D}_{t_0}^{\varsigma} h(t) = \frac{1}{\Gamma(1-\varsigma)} \left( \frac{d}{dt} \right) \int_{t_0}^{t} \left( \log \frac{t}{v} \right)^{-\varsigma} \frac{h'(v) - h(t_0)}{v} dv, \quad t > t_0 > 0.$$

This definition could be given in an equivalent way:

$$\mathcal{C H} \mathcal{D}_{t_0}^{\varsigma} h(t) = \frac{1}{\Gamma(1-\varsigma)} \int_{t_0}^{t} \left( \frac{d}{dt} \right)^{-\varsigma} h'(v) dv, \quad t > t_0 > 0.$$

More details about the Caputo–Hadamard derivative can be found in [11,27].

Definition 2. The generalized Mittag–Leffler function was represented as follows:

$$E_{\varsigma,q}(z) = \sum_{k=0}^{\infty} \frac{z^k}{\Gamma(k\varsigma + q)},$$

where $\varsigma > 0$, $q > 0$, $z \in \mathbb{C}$. 
When $q = 1$, one has $E_{\zeta}(z) = E_{\zeta,1}(z)$.

**Theorem 1** ([28]). Assume that $A \in \mathbb{R}^{d \times d}$ and the spectrum of $A$ satisfies:

$$\rho(A) \subset \{ \mu \in \mathbb{C}\setminus\{0\} : |\arg \mu| > \frac{\zeta \pi}{2} \}.$$  

Then, the following statements are true:

(i) $\lim_{t \to +\infty} \|E_{\zeta}(At^\zeta)\| = 0.$

(ii) $\int_{0}^{\infty} t^{\zeta-1} \|E_{\zeta,1}(At^\zeta)\| dt < \infty.$

3. **Combination Synchronization of Fractional-Order Systems**

In what follows, we provided the combination synchronization criterion of the fractional system in the sense of the Caputo–Hadamard derivatives. We considered the first time-varying fractional system of the following form:

$$\text{CH}_{t_0}^{\zeta} \mathcal{D}^\zeta p(t) = \mathcal{R}(t)p(t) + f(p(t)), \quad (1)$$

where $0 < \zeta \leq 1$, $\mathcal{R}(t) \in \mathbb{R}^{n \times n}$, $t > t_0 > 0$, and $f(p) \in \mathbb{R}^n$. The second time-varying fractional system could be given as:

$$\text{CH}_{t_0}^{\zeta} \mathcal{D}^\zeta q(t) = \mathcal{S}(t)q(t) + g(q(t)), \quad (2)$$

where $0 < \zeta \leq 1$, $\mathcal{S}(t) \in \mathbb{R}^{n \times n}$, and $g(q) \in \mathbb{R}^n$. Systems (1) and (2) could be considered as the drive system. Thereafter, we defined the response system as follows:

$$\text{CH}_{t_0}^{\zeta} \mathcal{D}^\zeta r(t) = \mathcal{T}(t)r(t) + h(r(t)), \quad (3)$$

where $0 < \zeta \leq 1$, $\mathcal{T}(t) \in \mathbb{R}^{m \times m}$, and $h(z) \in \mathbb{R}^m$. To recognize the combination synchronization of systems (1)–(3), we added a feedback control, $v(t) \in \mathbb{R}^m$, to system (3). Consequently, system (3) with feedback control was given as:

$$\text{CH}_{t_0}^{\zeta} \mathcal{D}^\zeta r(t) = \mathcal{T}(t)r(t) + h(r(t)) + v(t). \quad (4)$$

Now, we defined the combination synchronization error by:

$$e = r - M(p + q), \quad (5)$$

where $M$ is a scaling matrix. Using Equations (1), (2) and (4), we could obtain the error system by:

$$\text{CH}_{t_0}^{\zeta} \mathcal{D}^\zeta e(t) = \mathcal{T}(t)e(t) + \mathcal{T}(t)M(q(t) + p(t)) + h(r(t))$$

$$-M[S(t)q(t) + g(q(t)) + \mathcal{R}(t)p(t) + f(p(t))] + v(t). \quad (6)$$

Finally, the feedback control $v(t)$ was suggested as follows:

$$v(t) = M[S(t)q(t) + g(q(t)) + \mathcal{R}(t)p(t) + f(p(t))]$$

$$-\mathcal{T}(t)M(q(t) + p(t)) - h(r(t)) + \mathcal{S}(t)e(t), \quad (7)$$

where $\mathcal{S}(t) \in \mathbb{R}^{n \times m}$ is a feedback gain matrix which should be determined. Substituting Equation (7) into Equation (6), we obtained:

$$\text{CH}_{t_0}^{\zeta} \mathcal{D}^\zeta e(t) = (\mathcal{T}(t) + \mathcal{S}(t))e(t). \quad (8)$$
Equation (7) could be written as follows:

\[ CH_{\mathcal{G}^C_{t_0}} e(t) = (\mathcal{T} + \mathcal{N}) e(t) + (\mathcal{T}(t) + \mathcal{N}(t) - (\mathcal{T} + \mathcal{N})) e(t), \]  

(9)

where \( \mathcal{T} \) and \( \mathcal{N} \) are real matrices of the same size. If we assumed that \( \mathcal{A} = \mathcal{T} + \mathcal{N} \) and \( \mathcal{B}(t) = \mathcal{T}(t) + \mathcal{N}(t) - (\mathcal{T} + \mathcal{N}) \), then we had:

\[ CH_{\mathcal{G}^C_{t_0}} e(t) = \mathcal{A} e(t) + \mathcal{B}(t) e(t). \]

(10)

In the following theorem, we showed that \( \lim_{t \to +\infty} \|e(t)\| = 0 \). This meant that the combination synchronization would occur and be attained. It is worth noting that the following proof was based on the work conducted in [28].

**Theorem 2.** Assume that \( \mathcal{A} \) satisfies:

\[ \rho(\mathcal{A}) \subset \{ \mu \in \mathbb{C} \setminus \{0\} : |\arg \mu| > \frac{\kappa}{2} \}, \]

and \( \mathcal{B} \) satisfies:

\[ \lim_{t \to +\infty} \mathcal{B}(t) = 0, \]

(11)

then, \( \lim_{t \to +\infty} \|e(t)\| = 0 \).

**Proof.** According to Theorem 1, there was a constant \( \mathcal{Q} > 1 \), such that:

\[ \sup_{t \geq 0} \|E_{\mathcal{G}^C}(\mathcal{T} \mathcal{A})\| \sup_{t \geq t_0} \|\mathcal{B}(t)\| \leq \frac{\mathcal{Q}}{\Gamma(\xi)} \]

(12)

\[ \sup_{t \geq 0} \int_{t_0}^{t} t^{\xi-1} \|E_{\mathcal{G}^C}(\mathcal{A}^t)\| dt \leq \mathcal{Q}. \]

(13)

By (11), there existed \( T > t_0 \), such that:

\[ \sup_{t \geq T} \|\mathcal{B}(t)\| \leq \frac{1}{5 \mathcal{Q}}. \]

(14)

We considered the function \( \beta : [t_0, +\infty) \to [t_0, +\infty) \), such that:

\[ \beta(t) = \left\{ \begin{array}{ll} E_{\mathcal{G}^C}(5 \mathcal{Q}(\log(t) - \log(t_0)) \mathcal{A}) & \text{if } t_0 \leq t \leq T, \\ E_{\mathcal{G}^C}(5 \mathcal{Q}(\log(T) - \log(t_0)) \mathcal{A}) & \text{if } t \geq T. \end{array} \right. \]

We considered the norm \( \|\cdot\|_\beta \) in the space \( E = C_\infty([t_0, +\infty), \mathbb{R}^d) \) by \( \|z\|_\beta = \sup_{t \geq t_0} \|z(t)\|_\beta \) for any \( z \in C_\infty([t_0, +\infty), \mathbb{R}^d) \). Note that, \( \|\cdot\|_\beta \) is a Banach space.

Consider the operator \( \mathcal{R}_\kappa : C_\infty([t_0, +\infty), \mathbb{R}^d) \to C_\infty([t_0, +\infty), \mathbb{R}^d) \), with:

\[ \mathcal{R}_\kappa(x)(t) = E_\xi((\log(t) - \log(t_0))^\xi \mathcal{A}) x + \int_{t_0}^{t} (\log(t) - \log(s))^{\xi-1} E_{\mathcal{G}^C}((\log(t) - \log(s))^\xi \mathcal{A}) \frac{\mathcal{B}(s)}{s} \kappa(s) ds. \]

(13)

It followed from Theorem 1 that \( \mathcal{R}_\kappa(E) \subset E \).
Let $x \in \mathbb{R}^d$ and $\kappa, \tilde{\kappa} \in C_\infty \left( [t_0, +\infty), \mathbb{R}^d \right)$, we had:

$$\|\mathcal{R}_x(\kappa)(t) - \mathcal{R}_x(\tilde{\kappa})(t)\| \leq \int_{t_0}^{t} (\log(t) - \log(s))^{\xi-1} \|E_{\xi,\mathcal{A}}((\log(t) - \log(s))^{\xi}\mathcal{A})\|\|\mathcal{B}(s)\|\|\kappa(s) - \tilde{\kappa}(s)\| \, ds.$$  

For $t_0 \leq t \leq T$ we had:

$$\|\mathcal{R}_x(\kappa)(t) - \mathcal{R}_x(\tilde{\kappa})(t)\| \leq \frac{\|\kappa - \tilde{\kappa}\|_{\beta}}{\beta(t)} \int_{t_0}^{t} (\log(t) - \log(s))^{\xi-1} E_{\xi,\mathcal{A}}((\log(t) - \log(s))^{\xi}\mathcal{A}) \|\mathcal{B}(s)\| \, ds$$

$$\leq \frac{\|\kappa - \tilde{\kappa}\|_{\beta}}{\beta(t)} \frac{Q}{\Gamma(\xi)} \int_{t_0}^{t} (\log(t) - \log(s))^{\xi-1} \beta(s) \, ds.$$  

In addition, we had:

$$\frac{1}{\Gamma(\xi)} \int_{t_0}^{t} (\log(t) - \log(s))^{\xi-1} E_{\xi,\mathcal{A}}(5Q(\log(t) - \log(s))^{\xi}) \, ds$$

$$= \frac{1}{5Q} \left( E_{\xi,\mathcal{A}}(5Q(\log(t) - \log(t_0))^{\xi}) - 1 \right)$$

$$\leq \frac{1}{5Q} \left( E_{\xi,\mathcal{A}}(5Q(\log(t) - \log(t_0))^{\xi}) \right).$$

Then, for $t_0 \leq t \leq T$, we had:

$$\|\mathcal{R}_x(\kappa)(t) - \mathcal{R}_x(\tilde{\kappa})(t)\| \leq \frac{1}{5} \|\kappa - \tilde{\kappa}\|_{\beta}. \tag{15}$$

For $t \geq T$ we had:

$$\|\mathcal{R}_x(\kappa)(t) - \mathcal{R}_x(\tilde{\kappa})(t)\| \leq \frac{1}{\beta(t)} \left( \int_{t_0}^{T} (\log(t) - \log(s))^{\xi-1} E_{\xi,\mathcal{A}}((\log(t) - \log(s))^{\xi}\mathcal{A}) \|\mathcal{B}(s)\| (\kappa(s) - \tilde{\kappa}(s)) \, ds \right)$$

$$+ \frac{Q}{\Gamma(\xi)\beta(t)} \int_{t_0}^{t} (\log(t) - \log(s))^{\xi-1} (\kappa(s) - \tilde{\kappa}(s)) \, ds$$

$$+ \frac{\|\kappa - \tilde{\kappa}\|_{\beta}}{5Q} \int_{T}^{t} (\log(t) - \log(s))^{\xi-1} E_{\xi,\mathcal{A}}((\log(t) - \log(s))^{\xi}\mathcal{A}) \|\mathcal{B}(s)\| \, ds$$

$$\leq \frac{Q\|\kappa - \tilde{\kappa}\|_{\beta}}{\Gamma(\xi)\beta(t)} \int_{t_0}^{T} (\log(t) - \log(s))^{\xi-1} E_{\xi,\mathcal{A}}(5Q(\log(s) - \log(t_0))^{\xi}) \, ds.$$
\[ + \frac{\|\kappa - \tilde{\kappa}\|_\beta}{5Q} \int \frac{T}{t} (\log(t) - \log(s))^{\gamma - 1}\|E_{\gamma,r}((\log(t) - \log(s))^\gamma A)\| \, ds \]

Using the change of variable \( u = \log(t) - \log(s) \), we obtained:

\[ \int \frac{T}{t} (\log(t) - \log(s))^{\gamma - 1}\|E_{\gamma,r}((\log(t) - \log(s))^\gamma A)\| \, ds = \int_0^{\log(t) - \log(T)} u^{\gamma - 1}\|E_{\gamma,r}(u^\gamma A)\| \, du \leq M. \]

Therefore, for \( t \geq T \) we had:

\[ \frac{\|R_x(\kappa)(t) - R_x(\tilde{\kappa})(t)\|}{\beta(t)} \leq \frac{1}{2} \|\kappa - \tilde{\kappa}\|_\beta. \] (16)

Hence,

\[ \frac{\|R_x(\kappa) - R_x(\tilde{\kappa})\|}{\beta} \leq \frac{1}{2} \|\kappa - \tilde{\kappa}\|_\beta. \] (17)

Then, \( R_x \) was contractive on \( \left(C_\infty([t_0, +\infty), \mathbb{R}^d), \|\cdot\|_\beta\right) \).

Therefore, there existed a unique solution \( e \) of (10), which was bounded and satisfied \( e(t_0) = x \).

We had:

\[ e(t) = E_{\gamma}( (\log(t) - \log(t_0))^\gamma A) x + \int_{t_0}^T (\log(t) - \log(s))^{\gamma - 1}E_{\gamma,r}( (\log(t) - \log(s))^\gamma A) \frac{\beta(s)}{s} e(s) \, ds. \]

Let \( c = \lim_{t \to +\infty} \|e(t)\| \). Assume that \( c > 0 \).

Then, there existed \( T_1 > 0 \) such that \( \|e(t)\| < 2c, \forall t \geq T_1 \).

Let \( T_2 = \max(T, T_1) \). For any \( t \geq T_2 \), we had:

\[ e(t) \leq \|E_{\gamma}( (\log(t) - \log(t_0))^\gamma A) x \|
+ \int_{t_0}^T (\log(t) - \log(s))^{\gamma - 1}\|E_{\gamma,r}((\log(t) - \log(s))^\gamma A)\| \frac{\|\beta(s)\|}{s} \|e(s)\| ds
\]

\[ + \int_{T_1}^T (\log(t) - \log(s))^{\gamma - 1}\|E_{\gamma,r}((\log(t) - \log(s))^\gamma A)\| \frac{\|\beta(s)\|}{s} \|e(s)\| ds
\]

\[ \leq \|E_{\gamma}( (\log(t) - \log(t_0))^\gamma A) x \|
+ \sup_{t \geq t_0} \|e(t)\| \sup_{t \geq t_0} \|\beta(t)\| \int_{t_0}^T (\log(t) - \log(s))^{\gamma - 1}\|E_{\gamma,r}((\log(t) - \log(s))^\gamma A)\| \frac{ds}{s}
\]

\[ + \sup_{t \geq T_2} \|e(t)\| \sup_{t \geq T_2} \|\beta(t)\| \int_{T_2}^T (\log(t) - \log(s))^{\gamma - 1}\|E_{\gamma,r}((\log(t) - \log(s))^\gamma A)\| \frac{ds}{s}. \]

We had:

\[ \int_{t_0}^{T_2} (\log(t) - \log(s))^{\gamma - 1}\|E_{\gamma,r}( (\log(t) - \log(s))^\gamma A)\| \frac{ds}{s} = \int_{\log(t) - \log(t_0)}^{\log(t) - \log(T_2)} \|E_{\gamma,r}(u^\gamma A)\| \, du. \]
Then, using Theorem 1, we obtained:

\[
\int_{t_0}^{T_2} (\log(t) - \log(s))^{\varsigma-1} \|E_{\varsigma \varsigma}(\log(t) - \log(s))^{\varsigma} A\| \, ds \to 0, \quad \text{as} \quad t \to \infty.
\]

We had:

\[
\int_{T_2}^{t} (\log(t) - \log(s))^{\varsigma-1} \|E_{\varsigma \varsigma}(\log(t) - \log(s))^{\varsigma} A\| \, ds = \int_{0}^{\log(t) - \log(T_2)} u^{\varsigma-1} \|E_{\varsigma \varsigma}(u^{\varsigma} A)\| \, du \leq \int_{0}^{\infty} u^{\varsigma-1} \|E_{\varsigma \varsigma}(u^{\varsigma} A)\| \, du
\]

Then,

\[
c \leq \frac{2c}{5Q} \int_{0}^{\infty} u^{\varsigma-1} \|E_{\varsigma \varsigma}(u^{\varsigma} A)\| \, du \leq \frac{2c}{5},
\]

which was a contradiction. Thus, \( \lim_{t \to +\infty} \|e(t)\| = 0. \)

4. Numerical Simulations

In this section, numerical simulations for famous systems with Caputo–Hadamard derivatives were provided to clarify and verify the theoretical results obtained for the phenomenon of combination synchronization.

Example 1. Let the first drive system be the non-autonomous Chen system with the Caputo–Hadamard derivative \([29]\) as shown:

\[
\begin{align*}
\CH D_1^{\varsigma} p_1(t) & = (35 + \sin(t))(p_2 - p_1) \\
\CH D_1^{\varsigma} p_2(t) & = 28p_2 - p_1p_3 \\
\CH D_1^{\varsigma} p_3(t) & = -3p_3 + p_1p_2
\end{align*}
\]

(18)

According to Equation (1), we had:

\[
\mathbb{R}(t) = \begin{bmatrix} -35 + \sin(t) & 35 + \sin(t) & 0 \\ 0 & 28 & 0 \\ 0 & 0 & -3 \end{bmatrix}, \quad f(p(t)) = \begin{bmatrix} 0 \\ -p_1p_3 \\ p_1p_2 \end{bmatrix}.
\]

The second drive system was taken as the non-autonomous fractional-order Lorenz system \([30]\):

\[
\begin{align*}
\CH D_1^{\varsigma} q_1(t) & = -2(q_1 - q_2) \\
\CH D_1^{\varsigma} q_2(t) & = 10q_1 - \sin^2(2\pi t)q_2 - q_1q_3 \\
\CH D_1^{\varsigma} q_3(t) & = -\sin^2(2\pi t)q_3 + q_1q_2 - 10
\end{align*}
\]

(19)

System (19) could be expressed as system (2), where:

\[
\mathbb{S}(t) = \begin{bmatrix} -2 & 2 & 0 \\ 10 - \sin^2(2\pi t) & 0 & 0 \\ 0 & 0 & -\sin^2(2\pi t) \end{bmatrix}, \quad \mathbb{g}(q(t)) = \begin{bmatrix} 0 \\ -q_1q_3 \\ q_1q_2 - 10 \end{bmatrix}.
\]
The initial conditions of drive system (18) and the response system (20) were taken as
Lyapunov exponent was positive. This implied that the Chen system (18) was a chaotic system.
numerical simulations given in Figures 3 and 4, it was remarkable that the theoretical results were
implied that the two derive systems (18), (19) would attain combination synchronization with
combination synchronization error is shown in Figure 4. From the
proposed by Danca et al. [33], and this phenomenon could be identified by calculating the Lyapunov
over, to investigate the chaos phenomenon of the system (18), we modified the MATLAB code
and this led to \( \lim_{t \to +\infty} \eta(t) = 0 \). Moreover, since the eigenvalues of \( \mathcal{A} = \mathcal{T} + \mathcal{N} \) were \( \mu_1 = -2 \) and
and this implied that the condition of the spectrum of matrix \( \mathcal{A} \) satisfied. Thus, all hypotheses
Theorem 2 were achieved, and we could deduce that the combination synchronization phenomena
To obtain the numerical simulations, we used the modified predictor–corrector method [32]. Moreover,
investigate the chaos phenomenon of the system (18), we modified the MATLAB code
proposed by Danca et al. [33], and this phenomenon could be identified by calculating the Lyapunov
exponents (LEs). The corresponding Lyapunov exponents of system (18) were 0.3640, -0.0773, and
-2.0712. Figure 1 depicts the dynamics Lyapunov exponents, which showed that the first
Lyapunov exponent was positive. This implied that the Chen system (18) was a chaotic system.
Figure 2 displays the chaos of system (18) at \( \zeta = 0.98 \) and the initial condition \((-8, -10, 16)\).
The initial conditions of drive system (18) and the response system (20) were taken as \((1, 2, -5)\), and
\((0.1, 0.2)\), respectively. In addition, the corresponding initial condition of the error system was
given by \((-2.5, -5.5)\).

Figure 3 shows the time trajectories of states \( r_1(t) \), \( p_1(t) + q_1(t) \) and \( r_2(t) \), \( p_2(t) + q_2(t) \) and
\( p_3(t) + q_3(t) \), of the two derive systems (18) (19) and a response system (20), respectively, which
implied that the two derive systems (18), (19) would attain combination synchronization with
response system (20). The combination synchronization error is shown in Figure 4. From the
numerical simulations given in Figures 3 and 4, it was remarkable that the theoretical results were
satisfied.
Figure 1. Lyapunov exponent dynamics from a Chen system (18).

Figure 2. A 3D phase portrait of the non-autonomous Chen system (18).

Figure 3. Time trajectories of states $r_1(t)$, $p_1(t) + q_1(t)$ and $r_2(t)$, $p_2(t) + q_2(t) + p_3(t) + q_3(t)$, for Example 1.
Example 2. In this example, the Chen system [34] and the Lorenz system [35] with Caputo–Hadamard derivatives were used as the drive systems, while we considered the modified Van der Pol equation [36] with the Caputo–Hadamard derivative as the response system. The Chen and Lorenz systems with Caputo–Hadamard derivatives were given, respectively, by:

$$\text{CH}_{D_1}^p(t) = \begin{bmatrix} -\alpha & \alpha & 0 \\ \gamma & -\alpha & \gamma \\ 0 & 0 & -\beta \end{bmatrix} p(t) + \begin{bmatrix} 0 \\ -p_1 p_3 \\ p_1 p_2 \end{bmatrix},$$

$$\text{CH}_{D_1}^q(t) = \begin{bmatrix} -\zeta & \zeta & 0 \\ -\zeta & -1 & 0 \\ 0 & 0 & -\eta \end{bmatrix} q(t) + \begin{bmatrix} 0 \\ -q_1 q_3 \\ q_1 q_2 - \eta (\zeta + \rho) \end{bmatrix},$$

where $p(t) = [p_1(t), p_2(t), p_3(t)]^T$, $q(t) = [q_1(t), q_2(t), q_3(t)]^T$, $t > t_0 > 0$, $0 < \zeta \leq 1$ and $\alpha$, $\beta$, $\gamma$, $\zeta$, $\eta$, and $\rho$ are real parameters. The modified Van der Pol equation with the Caputo–Hadamard derivative was presented as:

$$\text{CH}_{D_1}^r(t) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & \sigma \end{bmatrix} r(t) + \begin{bmatrix} 0 \\ -\sigma \gamma^2 r_2 - r_3^3 + b \cos(t) \end{bmatrix} + v(t),$$

where $r(t) = [r_1(t), r_2(t)]^T$, $v(t) = [v_1(t), v_2(t)]^T$, $\sigma$ and $b$ were positive constants.

Now, if we chose matrices $M$ and $\mathcal{X}(t)$ as:

$$M = \begin{bmatrix} 1 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad \mathcal{X}(t) = \begin{bmatrix} -4 & 0 \\ 0 & \mu - 3 \end{bmatrix},$$

then the components of the feedback control were provided by:

$$v_1(t) = -\zeta q_1 + \zeta q_2 - \alpha p_1 + \alpha p_2 - \zeta q_1 - q_2 - q_1 q_3 + (\gamma - \alpha) p_1 + \gamma p_2 - p_1 p_3 - (p_3 + p_3) - 4(r_1 - (p_1 + q_1 + p_2 + q_2)),$$

$$v_2(t) = -\eta q_3 + q_1 q_2 - \eta (\zeta + \rho) - \beta p_3 + p_1 p_2 - \mu (p_3 + q_3) + \mu^2 r_2 + r_1^3 - b \cos(t) - (\sigma + 3)(r_2 - (p_3 + q_3)),$$

and we could obtain the combination synchronization error system by:
\[ CHD_1, e(t) = (T(t) + N(t))e(t) = \begin{bmatrix} -4 & 1 \\ 0 & -3 \end{bmatrix} e(t). \]

To verify Theorem 2, one could compute that:

\[ \lim_{t \to \infty} (T(t) + N(t)) = \begin{bmatrix} -4 & 1 \\ 0 & -3 \end{bmatrix} = T + N, \]

and this led to \( \lim_{t \to \infty} B(t) = 0. \) Furthermore, the corresponding eigenvalues of \( A = T + N, \) were given by \( \mu_1 = -4 \) and \( \mu_2 = -3, \) which implied that \( |\arg \mu| > \frac{\sqrt{2}}{2} \) satisfied. Therefore, the combination synchronization phenomena were achieved.

In the numerical simulations, the parameter values of the fractional-order Chen system, Lorenz system, and modified Van der Pol system were given as \((\alpha, \beta, \gamma) = (35, 3, 28), (\xi, \eta, \rho) = (10, 8/3, 28)\) and \((\sigma, \beta) = (1, 1)\), respectively. The initial states of the two drive systems and response system were arbitrarily chosen as \((-5, -7, 10), (5.5, 5.5, -0.5), \) and \((0, 5.5)\), respectively. Moreover, the initial state of the error vector was \((2, -5)\).

The dynamics of Lyapunov exponents of system \((24)\) are shown in Figure 5, where the corresponding LEs were \(0.7113 - 0.0675, \) and \(-2.6904\). Accordingly, it was obvious that the Chen system \((24)\) was chaotic.

Figure 6 elucidates the chaotic behavior of system \((24)\) at the given chosen parameters and \(\varsigma = 0.98.\) Figure 7 exhibits the identicality of the time trajectories of the states \(r_1(t), p_1(t) + q_1(t) + p_2(t) + q_2(t)\) and \(r_2(t), p_3(t) + q_3(t)\).

Furthermore, Figure 8 displays the error dynamics for the systems presented in Example 2. It was clear that the numerical results shown in all Figures confirmed the theoretical results.

Figure 5. Lyapunov exponent dynamics from a Chen system \((24)\).

Figure 6. A 3D phase portrait of the Chen system \((24)\).
5. Conclusions

In this paper, combination synchronization phenomena of several fractional-order systems employing the scaling matrix were discussed. To the best of our knowledge, the proposed synchronization for fractional-order systems involving the Caputo–Hadamard derivative has not been previously investigated. Combination synchronization was accomplished by taking into account two drive systems and one response system. We demonstrated that the phenomenon of combination synchronization could be achieved theoretically. In addition, numerical simulations were performed to demonstrate the feasibility and validity of the given theoretical analysis. Finally, the presented results pave the way for future research not only into various types of combination synchronization, such as using linear control, adaptive control, and active control, but also into investigating the possibility of extending the proposed synchronization to other fractional-order derivatives. Furthermore, in future work, we will investigate whether the proposed synchronization technique can be applied to a class of different fractional-order systems with unequal orders.
