Abstract

Background: Intrahepatic bile duct cyst calculus is an extremely rare case. We report a case of intrahepatic bile duct cyst calculus and gallbladder stones treated with surgery.

Case Presentation: A 76-year-old woman consulted our institution because of epigastric pain. Her blood chemistry results showed elevation of hepatic-cystic system enzymes. Computed tomography revealed cholecystitis with gallbladder stones and stones within an intrahepatic bile duct cyst at the root of the right hepatic duct, which was suspected as a sub-gallbladder. Endoscopic retrograde cholangiopancreatography and other examinations were performed. Finally, the patient was diagnosed with double gall bladder stones and cholecystitis, and she underwent surgery. Intrahepatic bile duct cyst (considered as accessory gallbladder) and gallbladder resections and hepaticojejunostomy were performed with laparotomy. She progressed well postoperatively and was discharged from the hospital on postoperative day 19. Postoperative histopathological examinations showed a definite diagnosis of intrahepatic bile duct cyst calculus and gall bladder stones with cholecystitis.

Conclusions: We report a case of intrahepatic bile duct cyst calculus and gallbladder stones treated with surgery. Decision of surgical procedure by the location of intrahepatic bile duct cystis essential for the treatment.

Keywords: Gall bladders tone; Intrahepatic bile duct cyst calculus; Type V bile duct cyst

Introduction

Acute cholecystitis is the most frequent complication of cholelithiasis, accounting for up to 20% of patients with symptomatic gallstones [1]. Acute cholecystitis is one of the most frequent causes of urgent admission at surgical departments due to the high prevalence of cholelithiasis [2].

The Todani classification scheme is typically used to classify bile duct cysts based on their location and morphology [3]. Todani type V cysts are described as single or multiple intrahepatic cystic dilations with no extra hepatic involvement. Type V cysts are a rare form of bile duct cyst, and solitary type V cysts are even less common, with an estimated incidence of 1:1,000,000 [4]. Solitary diverticular type V cysts are exceedingly rare. Complications associated with bile duct cysts include bile duct stenosis, cholangitis, bile duct stones, pancreatitis, and biliary malignant changes. The risk of biliary malignancies increases with age [5]. Subsequently, bile duct cysts are surgically managed with complete cyst excision and hepaticojejunostomy reconstruction or hepatectomy [6].

Here, we present a patient with solitary type V intrahepatic bile duct cyst with calculus and gallbladder stones treated with surgery.

Case Presentation

The patient was a 76-year-old female with epigastric pain. Her blood chemistry study results showed elevation of hepatic-cystic system enzymes (aspartate aminotransferase : 193U/L, alanine aminotransferase : 238U/L, alkaline phosphatase : 576U/L, total bilirubin : 1.5mg/dL, direct bilirubin : 0.8mg/dL, C-Reactive Protein : 26.8mg/L) and renal function parameters (Creatinine : 0.9mg/dL, Blood urea nitrogen : 15mg/dL, Glomerular filtration rate : 90mL/min).

The patient was referred for further evaluation. An upper gastrointestinal endoscopy was performed, which revealed no abnormal findings. An abdominal ultrasound was suggestive of gallstones and a possible cystic lesion in the right hepatic lobe. A computed tomography scan confirmed the presence of gallbladder stones and a cystic structure within the right hepatic lobe. The cystic structure was considered to be a sub-gallbladder. An endoscopic retrograde cholangiopancreatography (ERCP) was performed, which demonstrated dilatation of the intrahepatic bile ducts and a filling defect within the cystic structure. A biopsy was taken from the cystic structure, which showed evidence of cholecystitis.

The patient underwent laparotomy, and a cystic mass was found in the right hepatic lobe. A cystectomy was performed, and the cystic mass was found to be a solitary type V intrahepatic bile duct cyst. The cystic mass was excised, and the bile ducts were reconstructed using a hepaticojejunostomy. The gallbladder was also excised due to the presence of gallstones. The patient recovered well postoperatively and was discharged from the hospital on postoperative day 19.

Postoperative histopathological examination showed a definite diagnosis of solitary type V intrahepatic bile duct cyst calculus and gall bladder stones with cholecystitis.

Conclusions: We report a case of solitary type V intrahepatic bile duct cyst with calculus and gallbladder stones treated with surgery. The decision of surgical procedure by the location of intrahepatic bile duct cyst is essential for the treatment.
826U/L, gamma-glutamyl transpeptidase : 559U/L, total bilirubin : 4.0mg/dL, Creactive protein : 3.93mg/dL). Computed tomography revealed gallbladder enlargement, gallbladder wall thickening with gallbladder stones, common bile duct expansion (8mm), common bile duct stones and stones with in an intrahepatic cyst at the root of right hepatic duct, suspected as an accessory gallbladder (Figures 1A,B). Magnetic resonance cholangiopancreatography showed the same findings as computed tomography (Figures 2A,B). Subsequently, she was diagnosed with common bile duct stones, double gallbladder stones, and cholecystitis, and endoscopic retrograde cholangiopancreatography was performed. Cholangiopancreatography showed filling defects in the gallbladder, common bile duct, and intrahepatic cyst at the root of the right hepatic duct, which was suspected as an accessory gallbladder (Figure 3). Endoscopic sphincterotomy was performed for the common bile duct stones. No malfusion of the pancreaticobiliary ducts was observed. Two black stones were discharged from the common bile duct. One biliary stent was placed in to the common bile duct.

Figures 1(A,B): Cystic structure (white arrow) (A) and normal gallbladder (black arrow) (B) are confirmed by computed tomography.

Figures 2(A,B): (A) Common bile duct stones (white arrows) are confirmed by magnetic resonance cholangiopancreatography. (B) Cystic structure (white arrow) and normal gallbladder (black arrow) are also confirmed by magnetic resonance cholangiopancreatography.
Finally, surgical procedure was performed for double gallbladder stones and cholecystitis. First, laparoscopic surgery has been planned; however, almost all the intrahepatic bile duct (considered as accessory gallbladder) existed in the liver parenchyma (Figure 4A). Subsequently, intrahepatic bile duct (considered as accessory gallbladder) and gallbladder resections and hepaticojejunostomy were performed with laparotomy. She progressed well postoperatively and was discharged from the hospital on postoperative day 19. Postoperative histopathological examinations revealed no muscular layer in the wall of the intrahepatic cyst (considered as accessory gallbladder) (Figure 4B), and the definite diagnosis was intrahepatic bile duct cyst calculus and gallbladder stones with cholecystitis.

**Figure 3:** Cystic structure (white arrow) is confirmed by endoscopic retrograde cholangiopancreatography.

**Figures 4(A,B):** (A) Intraoperative image of the duct cyst during laparotomy (white arrow). Almost all intrahepatic bile ducts are in the liver parenchyma. (B) Microscopic image of the intrahepatic bile duct cyst. The muscular layer structure of the gallbladder could not be seen in the intrahepatic bile duct cyst.
Discussion

Bile duct cysts are rare worldwide, with an estimated incidence of 1 : 100,000-1:150,000 [7,8]. Early identification and treatment of bile duct cysts is recommended due to the potential for liver injury and malignant degeneration, presumably due to chronic cholestasis and cholangitis [9]. The risk of degeneration to cholangiocarcinoma is the highest for intrahepatic cysts [10]. The case reported here is exceptional because the intrahepatic cyst appears to be a single, diverticular lesion with no other apparent malformations of the biliary tree. To the best of our knowledge, only two previous cases of a solitary diverticular type V cyst have been reported in the literature [11,12].

In contrast, the preoperative diagnosis of this case was double gallbladder stones. Double gallbladder is a rare congenital anomaly, reported in 2 (0.02%) of 9921 autopsy cases and 3 (0.03%) of 9970 cases in a radiographic survey [13]. Gorecki et al. [14] reported a case of double gallbladder in a 69-year-old female with stones in both gallbladders with the accessory gallbladder originating from the left hepatic duct. In 2009, Kim et al. [15] have reported a 78-year-old male with duplicate gallbladder with stones arising from the left hepatic duct 10 years after an open cholecystectomy. However, postoperative histopathological examinations revealed no muscular layer in the wall of the intrahepatic cyst (considered as accessory gallbladder) in this case.

Complications associated with adult choleodochal cysts include bile duct stricture, cholangitis, bile duct stones, pancreatitis, and biliary malignant changes. Biliary malignancy is the most important among these complications. The incidence of biliary malignancy in adult choleodochal cysts is 9.8%-30%. The risk of biliary malignancies increases with age. Among 204 cases of adult choleodochal cysts, Cho et al. [16] found that the incidence of biliary malignancies was 3.9% for the 18-30 years age group, 6.9% for the 31-40 years age group, 10% for the 41-50 years age group, 10.7% for the 51-60 years age group, and 37.5% for the 61-67 years age group. Possible carcinogenic factors included chronic inflammation, cholestasis, and sparse distribution of the protective mucin-secreting glands of the bile duct. Under the influence of these factors, chronic irritation, ulceration, regeneration, and metaplasia of the epithelium of the cystic wall may develop, and invasive carcinoma may eventually occur. The most common type of biliary cancer is adenocarcinoma; only few cases have been reported for undifferentiated carcinoma, squamous cell carcinoma, and adenosquamous carcinoma [5].

Aggressive treatment (total resection or transplantation) has been proposed to lower the risk of subsequent cholangiocarcinoma [4]. In the current case, considering the presence of the stones and the relative respectability of the cyst, the benefits of surgical resection have been decided to outweigh the potential risks. However, this case is solitary intrahepatic bile duct, and the cystis partially outside the liver parenchyma. Subsequently, surgical procedures, such as hepatectomy or transplantation, are excessive invasive surgery. Intrahepatic bile duct cyst and gallbladder resection and hepaticojejunostomy seem to be reasonable procedure for this case.

Conclusions

In conclusion, we report a case of solitary type V intrahepatic bile duct cyst with calculus and gallbladder stones treated with surgery. Decision of surgical procedure by the location of intrahepatic bile duct cyst is essential for the treatment.
