Cyber-Physical Systems (CPSs) are integrations of networking and distributed computing systems with physical processes, where feedback loops allow physical processes to affect computations and vice versa. Although CPSs can be found in several real-world domains (automotive, avionics, energy supply, etc), their verification often relies on simulation test systems rather than formal methodologies. This is because there is still a lack of research on the modelling and the definition of formal semantics to compare non-trivial CPSs in terms of their runtime behaviours up to an acceptable tolerance.

We propose a hybrid probabilistic process calculus for modelling and reasoning on cyber-physical systems (CPSs). The dynamics of the calculus is expressed in terms of a probabilistic labelled transition system in the SOS style of Plotkin. This is used to define a bisimulation-based probabilistic behavioural semantics which supports compositional reasonings. For a more careful comparison between CPSs, we provide two compositional probabilistic metrics to formalise the notion of behavioural distance between systems, also in the case of bounded computations. Finally, we provide a non-trivial case study, taken from an engineering application, and use it to illustrate our definitions and our compositional behavioural theory for CPSs.

1 Introduction

Cyber-Physical Systems (CPSs) are integrations of networking and distributed computing systems with physical processes, where feedback loops allow physical processes to affect computations and vice versa. CPSs can be considered as an evolution of embedded systems, where components are immersed in and interact with the physical world, via physical devices (such as sensors and actuators). They can also be seen as an evolution of networked control systems, where physical processes and controllers interact via a communication system.

The physical plant of a CPS is often represented by means of a discrete-time state-space model consisting of two equations of the form

\[
\begin{align*}
x_{k+1} &= Ax_k + Bu_k + w_k \\
y_k &= Cx_k + e_k
\end{align*}
\]

where \(x_k \in \mathbb{R}^n\) is the current (physical) state, \(u_k \in \mathbb{R}^m\) is the input (i.e., the control actions implemented through actuators) and \(y_k \in \mathbb{R}^p\) is the output (i.e., the measurements obtained from the sensors). The uncertainty \(w_k \in \mathbb{R}^n\) and the measurement error \(e_k \in \mathbb{R}^p\) represent perturbation and sensor noise, respectively. The parameters \(A\), \(B\), and \(C\) are matrices modelling the dynamics of the physical system. The next state \(x_{k+1}\) depends on the current state \(x_k\) and the corresponding control actions \(u_k\), at the sampling instant \(k \in \mathbb{N}\). Note that, the state \(x_k\) cannot be directly observed: only its measurement \(y_k\) can be observed.

* A preliminary version appeared in the proceedings of LATA 2017, LNCS 10168, pp. 115-127, Springer [44].
1 We refer to [64] for a taxonomy of time-scale models used to represent CPSs.
A Probabilistic Calculus of Cyber-Physical Systems

Figure 1 Structure of a CPS

The physical plant is supported by a communication network through which the sensor measurements and actuator data are exchanged with the controller(s), i.e., the cyber component, also called logics, of a CPS (see Figure 1).

In general terms, CPSs can be considered as both nondeterministic and probabilistic systems. Nondeterminism arises as they consist of distributed networks in which the activities of specific components occur nondeterministically, whereas the probabilistic behaviour is due to the presence of the uncertainty in the model and the measurement error, which are usually represented as probability distributions.

The range of CPSs applications is rapidly increasing and already covers several domains [41]: advanced automotive systems, energy conservation, environmental monitoring, avionics, critical infrastructure control (for instance, electric power, water resources, and communications systems), etc.

However, there is still a lack of research on the modelling and validation of CPSs through formal methodologies that allow us to model the interactions among the system components, and to verify the correctness of a CPS, as a whole, before its practical implementation. A straightforward utilisation of these techniques is for model-checking [17], or even better, for probabilistic model-checking [42], to statically assess whether the current system deployment can guarantee the expected behaviour. However, they can also be an important aid for system planning, for instance to decide whether different deployments for a given application are behaviourally equivalent.

Process calculi have been successfully used to model and analyse concurrent, distributed and mobile systems (see, e.g., the π-calculus [50], Ambients [14] and the Distributed π-calculus [38]). However, to better describe systems based on a particular paradigm, dedicated calculi are needed. Hybrid process algebras [18, 7, 57, 54, 30] have been proposed for reasoning about physical systems and provide techniques for analysing and verifying protocols for hybrid automata. In order to enrich hybrid models with probabilistic or stochastic behaviour, a number of different approaches have been proposed in the last years [56, 39, 12, 2, 29, 36, 62]. However, to our knowledge, none of these formalisms provide bisimulation metrics semantics to estimate the deviation in terms of behaviour of different CPSs in a process-algebra setting. The definition of these instruments represents the main goal of the current paper.

In this paper, we propose a hybrid probabilistic process calculus, called pCCPS (Probabilistic Calculus of Cyber-Physical Systems), with a clearly-defined probabilistic behavioural semantics for specifying and reasoning on CPSs. In pCCPS, cyber-physical systems are represented by making a neat distinction between the physical component describing the physical process (consisting in state variables, sensors, actuators, evolution law, measurement law, etc.) and the cyber component, i.e., the logics (i.e., controllers, IDS, supervisors, etc.) that governs sensor reading and actuator writing, as well as channel-based communication with other cyber components. Thus, channels are used for logical interactions between cyber components, whereas sensors and actuators make possible the interaction between cyber and physical components. Despite this conceptual similarity, messages transmitted via
channels are “consumed” upon reception, whereas actuators’ states (think of a valve) remains unchanged until its controller modifies it.

pCCPS adopts a discrete notion of time \[\mathbb{N}\] and it is equipped with a probabilistic labelled transition semantics (pLTS) in the style of [55]. We prove that our probabilistic labelled transition semantics satisfies some standard time properties such as: time determinism, patience, maximal progress, and well-timedness. Based on our pLTS, we define a natural notion of weak probabilistic bisimilarity, written \(\approx\). As a main result, we prove that bisimilarity in pCCPS is preserved by appropriate system contexts and it is hence suitable for compositional reasoning. Then, we provide a non-trivial case study, taken from an engineering application, and use it to illustrate our definitions and our compositional behavioural theory for CPSs. We also use our case study to show that the probabilistic bisimilarity is only partially satisfactory to reason on CPSs as it can only establish whether two CPSs behave exactly in the same way or not. Any tiny variation of the probabilistic behaviour of one of the two systems under consideration will break the equality without any further information on the “distance” of their behaviours. To this end, bisimulation metric semantics have been successfully employed to formalise the behavioural distance between two systems [27, 26, 59, 21]. We generalise our probabilistic bisimilarity by providing a notion of weak bisimulation metric for pCCPS along the lines of [27]. We will write \(M \approx_p N\), if the weak bisimilarity between CPSs \(M\) and \(N\) holds with a distance \(p\), with probability \(p \in [0, 1]\). Intuitively, \(\approx\) will coincide with the weak probabilistic bisimilarity \(\approx\), whereas \(\bigcup_{p\in[0,1]} \approx_p\) will correspond to the cartesian product pCCPS \(\times\) pCCPS. We also provide a notion of \(n\)-bisimilarity metric which takes into account bounded computations of systems [26]. This kind of metric, denoted with \(\approx_n\), for \(n \in \mathbb{N}^+\), says that the distance \(p\) of the systems under considerations is ensured only for the first \(n\) computation steps. Said in other words, if \(M \approx_n N\) then for the first \(n\) computation steps the runtime behaviour of systems \(M\) and \(N\) may differ with probability \(p\). Both metrics \(\approx_p\) and \(\approx_n\) are proved to be preserved by the same contexts considered for \(\approx\), and hence they reveal to be suitable for compositional reasonings. In particular, they satisfy a well-known compositional property called non-expansiveness [26, 31, 33], the analogue of the congruence property of weak bisimulation. Finally, with the help of our case study, we will show how \(n\)-bisimilarity metric can be very helpful in situations where it is not necessary to observe a system “ad infinitum” as it makes much more sense to observe its behaviour for bounded computations.

Outline. In Section 2, we give syntax and operational semantics of pCCPS. In Section 3, we provide a bisimulation-based probabilistic behavioural semantics for pCCPS and prove its compositionality. In Section 4, we model our case study in pCCPS, and prove for it run-time properties as well as system equalities. In Section 5, we define bisimulation metrics for pCCPS. In Section 6, we revise our case study by providing a more accurate analysis based on the proposed bisimulation metrics. In Section 7, we draw conclusions and discuss related and future work.

2 The calculus

In this section, we introduce our Probabilistic Calculus of Cyber-Physical Systems, pCCPS.

Let us start with some preliminary notations. We use \(x, x_k \in X\) for state variables (associated to physical states of systems), \(c, d \in C\) for communication channels, \(a, a_k \in A\) for actuator devices, \(s, s_k \in S\) for sensors devices. Actuator names are metavariables for actuator devices like valve, light, etc. Similarly, sensor names are metavariables for sensor devices, e.g., a sensor thermometer that measures a state variable called temperature, with a given precision. Values, ranged over by \(v, v' \in V\), are built from basic values, such as Booleans, integers and real numbers; they also include names. Given a generic set of
names \( \mathbb{N} \), we write \( \mathbb{R}^{\mathbb{N}} \) to denote the set of functions assigning a real value to each name in \( \mathbb{N} \). For \( \xi \in \mathbb{R}^{\mathbb{N}} \), \( n \in \mathbb{N} \) and \( v \in \mathbb{R} \), we write \( \xi[n \mapsto v] \) to denote the function \( \psi \in \mathbb{R}^{\mathbb{N}} \) such that \( \psi(m) = \xi(m) \), for any \( m \neq n \), and \( \psi(n) = v \). Given \( \xi_1 \in \mathbb{R}^{\mathbb{N}_1} \) and \( \xi_2 \in \mathbb{R}^{\mathbb{N}_2} \) such that \( \mathbb{N}_1 \cap \mathbb{N}_2 = \emptyset \), we denote with \( \xi_1 \uplus \xi_2 \) the function in \( \mathbb{R}^{\mathbb{N}_1 \cup \mathbb{N}_2} \) such that \((\xi_1 \uplus \xi_2)(n) = \xi_1(n)\), if \( n \in \mathbb{N}_1 \), and \((\xi_1 \uplus \xi_2)(n) = \xi_2(n)\), if \( n \in \mathbb{N}_2 \).

As pCCPS is a probabilistic calculus, we report the necessary mathematical machinery for its formal definition.

**Definition 1** (Probability distribution). A (discrete) probability sub-distribution over a set of generic objects \( O \) is a function \( \delta : O \to [0, 1] \) with \( \sum_{o \in O} \delta(o) \in (0, 1] \). We write \( |\delta| \) as an abbreviation for \( \sum_{o \in O} \delta(o) \). The support of a probability sub-distribution \( \delta \) is given by \( \text{supp}(\delta) = \{ o \in O : \delta(o) > 0 \} \).

We write \( \mathcal{D}_{\text{sub}}(O) \), ranged over \( \gamma, \delta \) and \( \varepsilon \), for the set of all finite-support probability sub-distributions over the set \( O \). A probability sub-distribution \( \delta \in \mathcal{D}_{\text{sub}}(O) \) is said to be a probability distribution if \( \sum_{o \in O} \delta(o) = 1 \). With \( \mathcal{D}(O) \) we denote the set of all finite-support probability distributions over \( O \). For any \( o \in O \), the point (Dirac) distribution at \( o \), denoted \( \delta_o \), assigns probability 1 to \( o \) and 0 to all other elements of \( O \), so that \( \text{supp}(\delta_0) = \{ o \} \).

Let \( I \) be a finite indexing set such that (i) \( \delta_i \) is a sub-distribution in \( \mathcal{D}_{\text{sub}}(O) \) for each \( i \in I \), and (ii) \( p_i \geq 0 \) are probabilities such that \( \sum_{i \in I} p_i \in (0, 1] \). The probability sub-distribution (or convex combination) \( \sum_{i \in I} p_i \cdot \delta_i \) is the sub-distribution defined by \( (\sum_{i \in I} p_i \cdot \delta_i)(o) = \sum_{i \in I} p_i \delta_i(o) \) for all \( o \in O \). We write a sub-distribution as \( p_1 \cdot \delta_1 + \ldots + p_k \cdot \delta_k \) when the indexing set \( I \) is \( \{1, \ldots, k\} \).

In pCCPS, a cyber-physical system consists of:

- a physical component (defining physical variables, physical devices, physical evolution, etc.) and
- a cyber (or logical) component that interacts with the physical devices (sensors and actuators) and communicates via channels with other cyber components.

Physical components in pCCPS are given by two sub-components: (i) the physical state, which is supposed to change at runtime, and (ii) the physical environment, which contains static information.\(^2\)

**Definition 2** (Physical state). Let \( X \) be a set of state variables, \( S \) be a set of sensors, and \( A \) be a set of actuators. A physical state \( S \) is a triple \( (\xi_x, \xi_s, \xi_a) \), where:

- \( \xi_x \in \mathbb{R}^X \) is the state function,
- \( \xi_s \in \mathbb{R}^S \) is the sensor function,
- \( \xi_a \in \mathbb{R}^A \) is the actuator function.

All functions defining a physical state are total.

The state function \( \xi_x \) returns the current value associated to each variable in \( X \). The sensor function \( \xi_s \) returns the current value associated to each sensor in \( S \); similarly, the actuator function \( \xi_a \) returns the current value associated to each actuator in \( A \).

**Definition 3** (Physical environment). Let \( X \) be a set of state variables, \( S \) be a set of sensors, and \( A \) be a set of actuators. A physical environment \( E \) is a triple \( \langle \text{evol}, \text{meas}, \text{inv} \rangle \), where:

- \( \text{evol} : \mathbb{R}^X \times \mathbb{R}^A \to \mathcal{D}(\mathbb{R}^X) \) is the evolution map,
- \( \text{meas} : \mathbb{R}^X \to \mathcal{D}(\mathbb{R}^S) \) is the measurement map,
- \( \text{inv} \in \mathcal{D}(\mathbb{R}^X) \) is the invariant set.

All the functions defining a physical environment are total functions.

\(^2\)Actually, this information is periodically updated (say, every six months) to take into account possible drifts of the system.
Given a state function and an actuator function, the evolution map $\text{evol}$ returns a probability distribution over state functions. This function models the evolution law of the physical system, where changes made on actuators may reflect on state variables. Since we assume the presence of a known (maximal) uncertainty for our models, the evolution map does not return a specific state function but a probability distribution over state functions.

Given a state function, the measurement map $\text{meas}$ returns a probability distribution over sensor functions. Also in this case, since we assume the presence of a known (maximal) measurement error for each sensor, the measurement map returns a probability distribution over sensor functions, rather than a specific sensor function.

The invariant set $\text{inv}$ returns the set of state functions that satisfy the invariant of the system. A CPS that gets into a physical state with a state function that does not satisfy the invariant is in deadlock.

Let us now formalise the cyber components of CPSSs in our calculus pCCPS. Our (logical) processes build on Hennessy and Regan’s Timed Process Language TPL [37] (basically CCS enriched with a discrete notion of time). We extend TPL with three constructs: one to read values detected at sensors, one to write values on actuators, and one to express (guarded) probabilistic choice. The remaining processes of the calculus are the same as those of TPL.

**Definition 4 (Processes).** Processes are defined by the grammar:

$$
P, Q ::= \text{nil} \mid \text{tick}.C \mid P \parallel Q \mid [\text{chn}.C]D \mid \text{phy}.C \mid [b](P), \{Q\} \mid P\backslash C
$$

$$
C, D ::= \bigoplus_{i \in I} P_i; P_i
$$

$$
\text{chn} ::= \text{snd}c(v) \mid \text{rcv}c(x)
$$

$$
\text{phy} ::= \text{read}s(x) \mid \text{write}a(v).
$$

We write nil for the terminated process. The process $\text{tick}.C$ models sleeping for one time unit. We write $P \parallel Q$ to denote the parallel composition of concurrent processes $P$ and $Q$. The process $[\text{chn}.C]D$, with $\text{chn} \in \{\text{snd}c(v), \text{rcv}c(x)\}$, denotes channel transmission with timeout. Thus, $[\text{snd}c(v)].C]D$ sends the value $v$ on channel $c$ and, after that, it continues as $C$; otherwise, if no communication partner is available within one time unit, it evolves into $D$. The process $[\text{rcv}c(x).C]D$ is the obvious counterpart for channel reception.

Processes of the form $\text{phy}.C$ denote activities on physical devices (sensors or actuators). Thus, the construct $\text{read}s(x).C$ reads the value $v$ detected by the sensor $s$ and, after that, it continues as $C$, where $x$ is replaced by $v$. The process $\text{write}a(v).C$ writes the value $v$ on the actuator $a$ and then it continues as $C$.

The process $P\backslash C$ is the channel restriction operator of CCS. It is quantified over the set of communication channels, although we often use the shorthand $P\backslash \{c_1, \ldots, c_n\}$ to mean $P\backslash c_1 \backslash c_2 \cdots c_n$. The process $[b](P), \{Q\}$ is the standard conditional, where $b$ is a decidable guard. For simplicity, as in CCS, we identify process $[b](P), \{Q\}$ with $P$, if $b$ evaluates to true, and $[b](P), \{Q\}$ with $Q$, if $b$ evaluates to false. In processes of the form $[\text{chn}.C]D$ and $[\text{chn}.C]D$, the occurrence of $D$ is said to be time-guarded. The process $\text{rec}.X.P$ denotes time-guarded recursion as all occurrences of the process variable $X$ may only occur time-guarded in $P$.

The construct $\bigoplus_{i \in I} P_i; P_i$ denotes probabilistic choice, where $I$ is a finite, non-empty set of indexes, and $p_i \in (0, 1]$, for $i \in I$, denotes the probability to execute the process $P_i$, with $\sum_{i \in I} p_i = 1$. As in [24], in order to simplify the operational semantics, probabilistic choices occur always underneath prefixing.

In the two constructs $[\text{rcv}c(x).C]D$ and $\text{read}s(x).C$, the variable $x$ is said to be bound. Similarly, the process variable $X$ is bound in $\text{rec}.X.P$. This gives rise to the standard notions of free/bound (process) variables and $\alpha$-conversion. We identify processes up to $\alpha$-conversion (similarly, we identify CPSSs up to
A Probabilistic Calculus of Cyber-Physical Systems

renaming of state variables, sensor names, and actuator names). A term is closed if it does not contain free (process) variables, and we assume to always work with closed processes: the absence of free variables is preserved at run-time. As further notation, we write \( T \{ v / x \} \) for the substitution of the variable \( x \) with the value \( v \) in any expression \( T \) of our language. Similarly, \( T \{ f / x \} \) is the substitution of the process variable \( X \) with the process \( P \) in \( T \).

Everything is in place to provide the definition of cyber-physical systems expressed in \( p \text{CCPS} \).

**Definition 5** (Cyber-physical system). Fixed a set of state variables \( X \), a set of sensors \( S \), and a set of actuators \( A \), a cyber-physical system in \( p \text{CCPS} \) is given by two components:

- a physical component consisting of
  - a physical environment \( E \) defined on \( X \), \( S \), and \( A \), and
  - a physical state \( S \) recording the current values associated to the state variables in \( X \), the sensors in \( S \), and the actuators in \( A \);

- a cyber component \( P \) that interacts with the sensors in \( S \) and the actuators in \( A \), and can communicate, via channels, with other cyber components of the same or of other CPSs.

We write \( E; S \bowtie P \) to denote the resulting CPS, and use \( M \) and \( N \) to range over CPSs. Sometimes, when the physical environment \( E \) is clearly identified, we write \( S \bowtie P \) instead of \( E; S \bowtie P \). CPSs of the form \( S \bowtie P \) are called environment-free CPSs.

The reader should notice that the syntax of our CPSs is slightly too permissive as a process might use sensors and/or actuators which are not defined in the physical state.

**Definition 6** (Well-formedness). Let \( S = (\xi_S, \xi_S', \xi_{sa}) \) be a physical state, \( E = (\text{evol, meas, inv}) \) a physical environment, and \( P \) a process. The CPS \( E; S \bowtie P \) is said to be well-formed if: (i) any sensor mentioned in \( P \) is in the domain of the function \( \xi_S \); (ii) any actuator mentioned in \( P \) is in the domain of the function \( \xi_{sa} \). A sub-distribution \( \gamma \in \mathcal{D}_{\text{sub}}(p \text{CCPS}) \) is said to be well-formed if its support contains only well-formed CPSs.

Hereafter, we will always work with well-formed CPSs.

As usual in process calculi, we use the symbol \( \equiv \) to denote standard structural congruence for timed processes \([50, 42]\); its generalisation to CPSs is immediate: \( E; S \bowtie P \equiv E; S \bowtie Q \) if \( P \equiv Q \). Also the generalisation to sub-distributions in \( \mathcal{D}_{\text{sub}}(p \text{CCPS}) \) is straightforward: given two sub-distributions \( \gamma \) and \( \gamma' \) over CPSs, we write \( \gamma \equiv \gamma' \) if \( \gamma([M]) \equiv \gamma'([M]) \) for all equivalence classes \( [M] \subseteq p \text{CCPS} \).

Finally, we assume a number of notational conventions. We write Dead to denote a deadlocked CPS which cannot perform any action. This fictitious CPS will be useful when defining behavioural distances between CPSs (see [Definition 14]). We write \( \text{chn} P \) instead of \( \text{rec} X \cdot (\text{chn} \ P) \) \( X \), when \( X \) does not occur in \( P \). We write \( \text{snd} c \) (resp. \( \text{rcv} c \)) when channel \( c \) is used for pure synchronisation. For \( k \geq 0 \), we write \( \text{tick}^k \ P \) as a shorthand for \( \text{tick} \cdot \text{tick} \ldots \text{tick} \cdot \ P \), where the prefix \( \text{tick} \) appears \( k \) consecutive times. Given a CPS \( M = E; S \bowtie P \), a process \( Q \) and a channel \( c \), we write \( M \parallel Q \) for \( E; S \bowtie (P \parallel Q) \), and \( M \backslash c \) for \( E; S \bowtie (P \backslash c) \).

In the rest of the paper, symbol \( \sigma \) ranges over distributions over physical states, \( \pi \) ranges over distributions over processes, and \( \gamma \) ranges over distributions over CPSs.

### 2.1 Probabilistic labelled transition semantics

In this section, we provide the dynamics of \( p \text{CCPS} \) in terms of a probabilistic labelled transition system (pLTS) \([55]\). First, we give a pretty standard probabilistic LTS for processes, then we lift transition rules from processes to CPSs to deal with the probability distributions occurring in physical environments.

In Table 1 we provide transition rules for processes. Here, the meta-variable \( \lambda \) ranges over labels in the set \{\( \text{tick}, \tau, \tau v, cv, alv, s? \langle x \rangle \)\}. These labels denote the passage of time, internal activities, channel
transmission, channel reception, actuator writing, and sensor reading, respectively. As in [24], the definition of the labelled transition relation for processes relies on a semantic interpretation of probabilistic processes in terms of (discrete) probability distributions over processes.

**Definition 7.** For any probabilistic choice $\bigoplus_{i \in I} p_i; P$ over a finite index set $I$, we write $[\bigoplus_{i \in I} p_i; P]$ to denote the probability distribution $\sum_{i \in I} p_i \cdot P_i$.

The transition rules in Table 1 use some obvious notation for distributing both parallel composition and channel restriction over a sub-distribution. Given two sub-distributions $\pi_1$ and $\pi_2$ we define the sub-distribution $\pi_1 \parallel \pi_2$ as follows: $(\pi_1 \parallel \pi_2)(P) = \pi_1(P_1) \cdot \pi_2(P_2)$, if $P = P_1 \parallel P_2$; $(\pi_1 \parallel \pi_2)(P) = 0$, otherwise. Given an arbitrary distribution over processes $\pi = \sum_{i \in I} P_i$, an arbitrary channel $\chi$, and a value $v$, we define $\pi \chi$ as the distribution $\sum_{i \in I} P_i \cdot \pi_i \chi$, and $\pi_i \chi_i$ as the distribution $\sum_{i \in I} p_i \cdot P_i \chi_i / \chi_i$.

Let us comment on the transition rules of Table 1. Rules (Outp), (Inpp) and (Com) serve to model channel communication, on some channel $\chi$. Rule (Write) denotes the writing of some data $v$ on an actuator $a$. Rule (Read) denotes the reading of some value detected at sensor $s$. Rule (Par) propagates untimed actions over parallel components. Rules (ChnRes) and (Rec) are the standard rules for channel restriction and recursion, respectively. The following four rules are standard, and model the passage of one time unit. The symmetric counterparts of rules (Com) and (Par) are obvious and thus omitted from the table.

In Table 2 we lift the transition rules from processes to systems, actually to probability distributions overs systems. We adopt the following notation for probability distributions: given a distribution $\sigma$ over physical states and a distribution $\pi$ over processes, we write $\sigma \times \pi$ to denote the distribution over (environment-free) CPSs defined as $(\sigma \times \pi)(S \parallel P) = \sigma(S) \cdot \pi(P)$. Moreover, given a physical environment $E$, we write $E; \sigma \times \pi$ to extend the distribution $\sigma \times \pi$ to full CPSs as follows: $(E; \sigma \times \pi)(E; S \parallel P) = \sigma(S) \cdot \pi(P)$. Actions, ranged over by $\alpha$, are in the set $Act = \{\tau, \bar{v}, cv, tick\}$. These actions denote: non-observable activities ($\tau$); channel transmission ($\bar{v}$); channel reception ($cv$); the passage of time (tick).
Table 2 Probabilistic LTS for a CPS $S \times P$ parametric on an environment $E = \langle \text{evol}, \text{meas}, \text{inv} \rangle$

| Action | Transition | Invariant | Description |
|--------|------------|-----------|-------------|
| (Out)  | $P \xrightarrow{\tau v} \pi$ | $S \in \text{inv}$ | $S \times P \xrightarrow{\tau v} S \times \pi$ |
| (Inp)  | $P \xrightarrow{cv} \pi$ | $S \in \text{inv}$ | $S \times P \xrightarrow{cv} S \times \pi$ |
| (Tau)  | $P \xrightarrow{\tau} \pi$ | $S \in \text{inv}$ | $S \times P \xrightarrow{\tau} S \times \pi$ |
| (SensRead) | $P \xrightarrow{s(\xi)} \pi$ | $\xi \in \text{inv}$ | $P \xrightarrow{s(\xi)} \pi$ |
| (ActWrite) | $P \xrightarrow{a!v} \pi$ | $\xi \in \text{inv}$ | $P \xrightarrow{a!v} \pi$ |
| (Time) | $P \xrightarrow{\text{tick}} \pi$ | $S \times P \xrightarrow{\text{tick}} \pi$ | $S \times P \xrightarrow{\text{tick}} \text{next}_E(S) \times \pi$ |
| (Deadlock) | | $S \notin \text{inv}$ | $S \xrightarrow{\text{Dead}}$ |

As physical environments contain static information, for simplicity the resulting transition rules are parameterised on a physical environment of the form $E = \langle \text{evol}, \text{meas}, \text{inv} \rangle$. Thus, instead of providing the transitions rules for a CPS of the form $E; S \times P$ we give the LTS semantics parametric on $E$ for the environment-free CPS $S \times P$.

All rules, except (Deadlock), have a common premise requiring that the current state function of the system must satisfy the invariant. With an abuse of notation, we sometimes write $S \in \text{inv}$ instead of $\xi \in \text{inv}$ when $S = \langle \xi, \xi, \xi \rangle$. Rules (Out) and (Inp) model transmission and reception, with an external system, on a channel $c$. Rule (Tau) lifts non-observable actions from processes to systems. Rule (SensRead) models the reading of the current data detected at sensor $s$. Rule (ActWrite) models the writing of a value $v$ on an actuator $a$. A similar lifting occurs in rule (Time) for timed actions, where $\text{next}_E(S)$ returns a probability distribution over possible physical states for the next time slot, according to the current physical state $S$ and physical environment $E$. Formally, for $S = \langle \xi, \xi, \xi \rangle$ and $E = \langle \text{evol}, \text{meas}, \text{inv} \rangle$, we define:

$$\text{next}_E(S) = \sum_{\xi' \in \text{supp}(\text{evol}(\xi), \xi)} \text{evol}(\xi, \xi)(\xi') \cdot \text{meas}(\xi')(\xi') \cdot (\xi, \xi, \xi).$$

Intuitively, the operator $\text{next}_E$ serves to compute the possible state functions and sensor functions of the next time slot (actuator changes are governed by the cyber-component). More precisely, the (probability distribution over the) next state function is determined by applying $\text{evol}$ to the current state function $\xi$ and the current actuator function $\xi_a$. The probability weight of any possible state function $\xi'$ is given by $\text{evol}(\xi, \xi_a)(\xi')$. Then, for a state function $\xi'$, the (probability distribution over the) next sensor function is given by applying $\text{meas}$ to $\xi'$. Finally, the probability weight of any possible sensor function $\xi'$ is given by $\text{meas}(\xi')(\xi')$.

Recapitulating, by an application of rule (Time) a CPS moves to the next physical state, in the next time slot. Rule (Deadlock) is straightforward: if the invariant is not satisfied then the CPS deadlocks.

Finally, notice that in our LTS we defined transitions rules of the form $S \times P \xrightarrow{\alpha} \sigma \times \pi$, parametric on some physical environment $E$. As physical environments do not change at runtime, $S \times P \xrightarrow{\alpha} \sigma \times \pi$ entails $E; S \times P \xrightarrow{\alpha} E; \sigma \times \pi$, thus providing the probabilistic LTS for (full) CPSs.

Remark 1. Note that the rules in Table 2 define an image finite pLTS. This means that for any CPS $M$ and
label $\alpha$ there are finitely many distributions reachable from $M$ in one $\alpha$-labelled transition step. Moreover, all transitions $M \stackrel{\alpha}{\longrightarrow} \gamma$ are such that $\gamma$ has a finite support.

Now, having defined the labelled transitions that can be performed by a CPS of the form $E; S \bowtie P$, we can easily concatenate these transitions to define the possible computation traces of a system. A computation trace \[3\] for a CPS $E; S_1 \bowtie P_1$ is a sequence of steps of the form $E; S_1 \bowtie P_1 \stackrel{\alpha_1}{\longrightarrow} \ldots \stackrel{\alpha_{n-1}}{\longrightarrow} E; S_n \bowtie P_n$ where for any $i$, with $1 \leq i \leq n - 1$, we have $E; S_i \bowtie P_i \stackrel{\alpha_i}{\longrightarrow} E; \sigma_{i+1} \bowtie \pi_{i+1}$ for distributions $\sigma_{i+1}$ and $\pi_{i+1}$ such that $\sigma_{i+1} \in \text{supp}(\pi_{i+1})$ and $\pi_{i+1} \in \text{supp}(\sigma_{i+1})$.

Below, we report a few desirable time properties \[37\] which hold in our calculus: (a) time determinism, (b) maximal progress, (c) patience, and (d) well-timedness. In its standard formulation, time determinism says that a system reaches at most one new state by executing a timed action \(\text{tick}\); however, in our setting, this holds only for the logical components (up to structural congruence) whereas the evolution of the physical component is intrinsically probabilistic, due to the presence of uncertainty and measurement errors. The maximal progress property usually says that processes communicate as soon as a possibility of communication arises. In our calculus, we generalise this property saying that instantaneous (silent) actions cannot be delayed. On the other hand, patience says that if no instantaneous actions are possible then time is free to pass. Finally, well-timedness \[49\] \[15\] ensures the absence of infinite instantaneous traces which would prevent the passage of time, and hence the physical evolution of a CPS.

**Theorem 1** (Time properties). Let $M = E; S \bowtie P$.

- (a) If $M \stackrel{\text{tick}}{\longrightarrow} \gamma$ and $M \stackrel{\text{tick}}{\longrightarrow} \gamma'$ then $\gamma \equiv \gamma'$.
- (b) If $M \stackrel{\tau}{\longrightarrow} \gamma$ then there is no $\gamma'$ such that $M \stackrel{\text{tick}}{\longrightarrow} \gamma'$.
- (c) If $M \stackrel{\text{tick}}{\longrightarrow} \gamma$ for no $\gamma$ then either $S$ does not satisfy the invariant of $E$ or there is $\gamma'$ such that $M \stackrel{\tau}{\longrightarrow} \gamma'$.
- (d) There is a $k \in \mathbb{N}$ such that if $M \stackrel{\alpha_1}{\longrightarrow} \ldots \stackrel{\alpha_n}{\longrightarrow} N$, with $\alpha_i \neq \text{tick}$, then $n \leq k$.

The proof of Theorem 1 can be found in the Appendix, in Section A.1.

3 Problembial bisimulation

In this section, we are ready to define a bisimulation-based behavioural equality for CPSs, relying on our labelled transition semantics. We recall that the only observable activities in pCCPS are: the passage of time and channel communication. As a consequence, the capability to observe physical events (different from deadlocks) depends on the capability of the cyber components to recognise those events by acting on sensors and actuators, and then signalling them using (unrestricted) channels.

In a probabilistic setting, the definition of weak transition $\overset{\alpha}{\Rightarrow}$, which abstract away non-observable actions, is complicated by the fact that (strong) transitions take CPSs to distributions over CPSs. Following \[24\] \[47\], we need to generalise transitions, so that they take sub-distributions to sub-distributions.

With an abuse of notation, we use $\gamma$ and $\gamma'$ to range over sub-distributions over CPSs, under the assumption that $\sum_{M \in \text{pCCPS}} \gamma(M) \leq 1$.

Let us start with defining the weak transition $M \overset{\alpha}{\Rightarrow} \gamma$ for any CPS $M$ and distribution $\gamma$. If $\alpha = \tau$ then we write $M \overset{\alpha}{\Rightarrow} \gamma$ whenever either $M \overset{\alpha}{\Rightarrow} \gamma$ or $\gamma = M$. Otherwise, if $\alpha \neq \tau$ then we write $M \overset{\alpha}{\Rightarrow} \gamma$ whenever $M \overset{\alpha}{\Rightarrow} \gamma$. The relation $\overset{\alpha}{\Rightarrow}$ is extended to model transitions from sub-distributions to sub-distributions. For a sub-distribution $\gamma = \sum_{i \in I} P_i \cdot \bar{M}_i$, we write $\gamma \overset{\alpha}{\Rightarrow} \gamma'$ if there is a non-empty set $J \subseteq I$ such that $M_j \overset{\alpha}{\Rightarrow} \gamma_j$ for all $j \in J, M_i \overset{\alpha}{\Rightarrow} \gamma_j$, for all $i \in I \setminus J$, and $\gamma' = \sum_{j \in J} P_j \cdot \gamma_j$. Note that if $\alpha \neq \tau$ then this definition entails that
only some CPSs in the support of $\gamma$ have an $\hat{\alpha} \rightarrow$ transition. Then, we define the weak transition relation $\hat{\alpha} \Rightarrow$ as the transitive and reflexive closure of $\hat{\alpha} \rightarrow$, i.e. $\hat{\alpha} \Rightarrow = (\hat{\alpha} \rightarrow)^*$. While for $\alpha \neq \tau$ we let $\hat{\alpha} \Rightarrow$ denote $\hat{\alpha} \rightarrow \hat{\alpha} \rightarrow$.

In order to define a probabilistic bisimulation, following [23] we rely on the notion of matching [61] (also known as coupling) for a pair of distributions. Intuitively, the matching for a pair $(\gamma, \gamma')$ may be understood as a transportation schedule for the shipment of probability mass from $\gamma$ to $\gamma'$. 

**Definition 8 (Matching).** A matching for a pair of distributions $(\gamma, \gamma')$, with $\gamma, \gamma' \in \mathcal{D}(\text{pCCPS})$, is a distribution $\omega$ in the product space $\mathbb{D}(\text{pCCPS} \times \text{pCCPS})$ such that:

- $\sum_{M \in \text{pCCPS}} \omega(M, M') = \gamma(M)$, for all $M \in \text{pCCPS}$, and
- $\sum_{M' \in \text{pCCPS}} \omega(M, M') = \gamma'(M')$, for all $M' \in \text{pCCPS}$.

We write $\Omega(\gamma, \gamma')$ to denote the set of all matchings for $(\gamma, \gamma')$.

Everything is in place to define weak probabilistic bisimulation for pCCPS, along the lines of [53].

**Definition 9 (Weak probabilistic bisimulation).** A binary symmetric relation $\mathcal{R}$ over CPSs is a weak probabilistic bisimulation if $M \mathcal{R} N$ and $M \xrightarrow{\alpha} \gamma$ implies that there exist a distribution $\gamma'$ and a matching $\omega \in \Omega(\gamma, \gamma')$ such that $N \xrightarrow{\omega} \gamma'$, and $M' \mathcal{R} N'$ whenever $\omega(M', N') > 0$. We say that $M$ and $N$ are bisimilar, written $M \approx N$, if $M \mathcal{R} N$ for some weak probabilistic bisimulation $\mathcal{R}$.

A main result of the paper is that bisimilarity can be used to reason on CPSs in a compositional manner. In particular, bisimilarity is preserved by parallel composition of physically-disjoint CPSs, by parallel composition of pure-logical processes, and by channel restriction; basically, all those contexts that cannot interfere on physical devices (sensors and actuators), whereas interferences on logical components (via channel communication) is allowed.

Intuitively, two CPSs are physically-disjoint if they have different plants but they may share logical channels for communication purposes. More precisely, physically-disjoint CPSs have disjoint state variables and disjoint physical devices (sensors and actuators). As we consider only well-formed CPSs (Definition 6), this ensures us that a CPS cannot physically interfere with a parallel CPS by acting on its physical devices. Although, logical interferences on communication channels are allowed.

Formally, let $S_i = (\xi^1_i, \xi^2_i, \xi^3_i)$ and $E^i = (\text{evol}^i, \text{meas}^i, \text{inv}^i)$ be physical states and physical environments, respectively, associated to state variables in the set $X_i$, sensors in the set $S_i$, and actuators in the set $A_i$, for $i \in \{1, 2\}$. For $X_1 \cap X_2 = \emptyset$, $S_1 \cap S_2 = \emptyset$ and $A_1 \cap A_2 = \emptyset$, we define:

- the disjoint union of the physical states $S_1$ and $S_2$, written $S_1 \sqcup S_2$, to be the physical state $\langle \xi_x, \xi_s, \xi_a \rangle$ such that: $\xi_x = \xi^1_x \sqcup \xi^2_x$, $\xi_s = \xi^1_s \sqcup \xi^2_s$, $\xi_a = \xi^1_a \sqcup \xi^2_a$.
- the disjoint union of the physical environments $E_1$ and $E_2$, written $E_1 \sqcup E_2$, to be the physical environment $\langle \text{evol}, \text{meas}, \text{inv} \rangle$ such that:

  \[
  (\text{evol}(\xi^1_x \sqcup \xi^2_x, \xi^1_s \sqcup \xi^2_s)) = \text{evol}^1(\xi^1_x, \xi^1_s) \cdot \text{evol}^2(\xi^2_x, \xi^2_s), \\
  (\text{meas}(\xi^1_x \sqcup \xi^2_x)) = \text{meas}^1(\xi^1_x) \cdot \text{meas}^2(\xi^2_x), \\
  \text{inv}(\xi^1_x \sqcup \xi^2_x) = \text{inv}^1(\xi^1_x) \cdot \text{inv}^2(\xi^2_x). \]

- iff $\xi_x^1 \in \text{inv}^1$ and $\xi_x^2 \in \text{inv}^2$.

**Definition 10 (Physically-disjoint CPSs).** Let $M_i = E_i; S_i \parallel P_i$, for $i \in \{1, 2\}$. We say that $M_1$ and $M_2$ are physically-disjoint if $S_1$ and $S_2$ have disjoint sets of state variables, sensors and actuators. In this case, we write $M_1 \sqcup M_2$ to denote the CPS defined as $(E_1 \sqcup E_2); (S_1 \sqcup S_2) \parallel (P_1 \parallel P_2)$. For any $M \in \text{pCCPS}$, the special system $\text{Dead}$ is physically-disjoint with $M$, and $M \sqcup \text{Dead} = \text{Dead} \sqcup M = \text{Dead}$. 

A pure-logical process is a process which may interfere on communication channels but it never interferes on physical devices as it never accesses sensors and/or actuators. Basically, a pure-logical process is a (possibly probabilistic) TPL process [37]. Thus, in a system \( M \parallel Q \), where \( M \) is an arbitrary CPS, a pure-logical process \( Q \) cannot interfere with the physical evolution of \( M \). Although, process \( Q \) can definitely interact with \( M \) via communication channels, and hence affect its observable behaviour.

**Definition 11** (Pure-logical processes). A process \( P \) is called pure-logical if it never acts on sensors and/or actuators.

Now, we can finally prove the compositionality of probabilistic bisimilarity \( \approx \).

**Theorem 2** (Congruence results). Let \( M \) and \( N \) be two arbitrary CPSs in \( pCCPS \).

1. \( M \approx N \) implies \( M \oplus O \approx N \oplus O \), for any physically-disjoint CPS \( O \);
2. \( M \approx N \) implies \( M \parallel P \approx N \parallel P \), for any pure-logical process \( P \);
3. \( M \approx N \) implies \( M \setminus c \approx N \setminus c \), for any channel \( c \).

The proof can be found in the Appendix, at the end of Section A.3.

The reader may wonder whether the bisimilarity \( \approx \) is preserved by more permissive contexts. The answer is no. Suppose to allow in the second item of Theorem 2 a process \( P \) that can also read on sensors. In this case, even if \( M \) and \( N \) are bisimilar, the parallel process \( P \) might read a different value in the two systems at the very same sensor \( s \) (due to the sensor error) and transmit these different values on a free channel, breaking the congruence. Activities on actuators may also lead to different behaviours of the compound systems: bisimilar CPSs may have physical components that are not exactly aligned. A similar reasoning applies when composing CPSs with non physically-disjoint ones: interference on physical devices may break the congruence.

However, in the next section we will see that the congruence results of Theorem 2 will be very useful when reasoning on complex systems.

### 4 Case study

In this section, we provide a case study to illustrate how \( pCCPS \) can be used to specify and reason on CPSs in a compositional manner. In particular, we model an engine whose temperature is maintained within a specific range by means of a cooling system.

As regards the physical environment we adopt discrete uniform distributions over suitable intervals to model both the evolution map and the measurement map [3]. In our model, we assume a granularity \( g \in \mathbb{N}^+ \) representing the precision \( 10^{-g} \) of the model in estimating physical values. Thus, for an arbitrary real interval \([v, w]\) we write \([v, w]_g\) to denote the finite set of reals \( \{k \in [v, w] : k = v + h \cdot 10^{-g}, \text{with } h \in \mathbb{N}\} \).

Given a granularity \( g \in \mathbb{N}^+ \), the physical state \( S_g \) of the engine is characterised by: (i) a state variable \( \text{temp} \) containing the current temperature of the engine; (ii) a sensor \( s_t \) (such as a thermometer or a thermocouple) measuring the temperature of the engine, (iii) an actuator \( \text{cool} \) to turn on/off the cooling system. The physical environment of the engine, \( \text{Env}_g \), is constituted by: (i) a simple evolution law \( \text{evol} \) that increases (resp. decreases) the value of \( \text{temp} \), when the cooling system is inactive (resp. active), by a value determined according to a discrete distribution of probability, taking into account an uncertainty in the model that may reach the threshold \( \delta = 0.4 \), and granularity \( g \) over reals; (ii) a measurement map \( \text{meas} \) returning the value detected by the sensor \( s_t \) determined by a discrete probability distribution based

---

3 Other forms of finite-support discrete probability distributions could be treated as well.
on a measurement error that may reach the threshold $\text{err} = 0.1$, and granularity $g$; (ii) an invariant set saying that the system gets faulty when the temperature of the engine gets out of the range $[0,30]$. Formally, $\mathcal{S}_g = \langle \xi^g, \xi_s, \xi_a \rangle$ and $\mathcal{E}_g = \langle \text{evol}, \text{meas}, \text{inv} \rangle$ with:

(i) $\xi_x \in \mathbb{R}^{\text{temp}}$ and $\xi_x(\text{temp}) = 0$;

(ii) $\xi_s \in \mathbb{R}^{\{\text{on}\}}$ and $\xi_s(\text{temp}) = 0$;

(iii) $\xi_a \in \mathbb{R}^{\{\text{cool}\}}$ and $\xi_a(\text{cool}) = \text{off}$; for the sake of simplicity, we can assume $\xi_a$ to be a mapping $\{\text{cool}\} \rightarrow \{\text{on}, \text{off}\}$ such that $\xi_a(\text{cool}) = \text{off}$ if $\xi_a(\text{cool}) \geq 0$, and $\xi_a(\text{cool}) = \text{on}$ if $\xi_a(\text{cool}) < 0$.

Furthermore,

(i) $\text{evol}(\xi_x', \xi_s') = \sum_{v \in [v_1, v_2]} [\text{temp} \mapsto \xi_x'(\text{temp}) + v]$, for any $\xi_x' \in \mathbb{R}^{\{\text{temp}\}}$ and $\xi_s' \in \mathbb{R}^{\{\text{cool}\}}$,

where $[v_1, v_2] = [1-\delta, 1+\delta]$, if $\xi_s'(\text{cool}) = \text{off}$ (inactive cooling), and $[v_1, v_2] = [-1-\delta, -1+\delta]$, if $\xi_s'(\text{cool}) = \text{on}$ (active cooling);

(ii) $\text{meas}(\xi_x') = \sum_{v \in [-\text{err}, \text{err}]} [\text{temp} \mapsto \xi_x'(\text{temp}) + v]$, for any $\xi_x' \in \mathbb{R}^{\{\text{temp}\}}$;

(iii) $\text{inv} = \{\text{temp} \mapsto x : x \in \mathbb{R}$ and $0 \leq x \leq 30\}$.

The cyber component of the engine consists of a process $\text{Ctrl}$ which models the controller activity. Intuitively, process $\text{Ctrl}$ senses the temperature of the engine at each time interval. When the sensed temperature is above 10, the controller activates the coolant. The cooling activity is maintained for 5 consecutive time units. After that time, if the temperature does not drop below 10 then the controller transmits its ID on a specific channel for signalling a warning, it keeps cooling for another 5 time units, and then checks again the sensed temperature; otherwise, if the sensed temperature is not above the threshold 10, the controller turns off the cooling and moves to the next time interval. Formally,

\[
\begin{align*}
\text{Ctrl} & = \text{recX.reads}(s)(x > 10)\{\text{Cooling}\}, \{\text{tick}.X\} \\
\text{Cooling} & = \text{write cool(on)} \cdot \text{recY.tick} \cdot \text{read s}(x) \cdot [x > 10] \{\text{snd warning(ID).Y}, \{\text{write cool(off)}.tick}.X\} .
\end{align*}
\]

The whole engine is defined as: $\text{Eng}_g = \mathcal{E}_g ; \mathcal{S}_g \bowtie \text{Ctrl}$, where $\mathcal{E}_g$ and $\mathcal{S}_g$ are the physical environment and the physical state defined before.

Our operational semantics allows us to formally prove a number of run-time properties of our engine. For instance, the following proposition says that our engine never reaches a warning state and never deadlocks.

**Proposition 1.** Let $\text{Eng}_g$ be the CPS defined before. Given any computation $\text{Eng}_g \xrightarrow{\alpha_1} \ldots \xrightarrow{\alpha_n} M$, then $\alpha_i \in \{\text{tau}, \text{tick}\}$, for $1 \leq i \leq n$, and there is a distribution $\gamma$ such that $M \xrightarrow{\alpha} \gamma$, for some $\alpha \in \{\text{tau}, \text{tick}\}$.

Actually, knowing that in each of the 5 time slots of cooling, the temperature will drop of a value laying in the interval $[1-\delta, 1+\delta]$, we can be quite precise on the temperature reached by the engine before and after the cooling activity. Formally:

**Proposition 2.** Let $\text{Eng}_g \xrightarrow{\alpha_1} \ldots \xrightarrow{\alpha_n} M$ be an arbitrary computation of the engine, for some CPS $M$:

- if $M$ turns the cooling on then the value of the state variable temp in $M$ ranges over $[9.9, 11.5]$;
- if $M$ turns the cooling off then the value of the variable temp in $M$ ranges over $[2.9, 8.5]$.

The proofs of both propositions can be found in the Appendix, in Section A.2.

The result formally proved in [Proposition 2] finds a correspondence in the left graphic of [Figure 2]. In that graphic, we collect a campaign of 100 simulations of our engine in MATLAB lasting 250 time units.

\[^4\text{MATLAB chooses a value in a real interval by means of a discrete uniform distribution depending on the granularity imposed by the finite number of bits used for the representation of floats.}\]
The right graphic of the same figure shows three possible evolutions in time of the state variable temp: (i) the first one (in red), in which the temperature of the engine always grows of $1 - \delta = 0.6$ degrees per time step, when the cooling is off, and always decrease of $1 + \delta = 1.4$ degrees per time unit, when the cooling is on; (ii) the second one (in blue), in which the temperature always grows of $1 + \delta = 1.4$ degrees per time unit, when the cooling is off, and always decrease of $1 - \delta = 0.6$ degrees per time unit, when the cooling is on; (iii) and a third one (in yellow), in which, depending whether the cooling is off or on, at each time step the temperature grows or decreases of an arbitrary offset laying in the interval $[1 - \delta, 1 + \delta]$.

Now, the reader may wonder whether it is possible to design a variant of our engine which meets the same specification with better performances. For instance, an engine consuming less coolant. Let us consider a variant of the engine described before:

$$\widetilde{\text{Eng}}_g = \widetilde{\text{Env}}_g \times S_g \times \text{Ctrl}.$$  

Here, $\widetilde{\text{Eng}}_g$ is the same as $\text{Eng}_g$ except for the evolution map, as we set $[v_1, v_2] = [-0.8 - \delta, -0.8 + \delta]$ if $\xi'_a(\text{cool}) = \text{on}$ (active cooling). This means that in $\widetilde{\text{Eng}}_g$ we reduce the power of the cooling system by $20\%$. In Figure 3, we report the results of our simulations in MATLAB over 10000 runs lasting 10000 time units each. From this graph, $\widetilde{\text{Eng}}_g$ saves in average more than $10\%$ of coolant with respect to $\text{Eng}_g$. So, the new question is: are these two engines behavioural equivalent? Do they meet the same specification?

Our bisimilarity provides us with a precise answer to these questions: the two variants of the engine are bisimilar.

**Proposition 3.** $\text{Eng}_g \approx \widetilde{\text{Eng}}_g$, for any $g \in \mathbb{N}^+$.  

The proof can be found in the Appendix, in Section A.4.

At this point, one may wonder whether it is possible to improve the performances of our engine even more. For instance, by reducing the power of the cooling system by a further $10\%$, by setting $[v_1, v_2] = [-0.7 - \delta, -0.7 + \delta]$ if $\xi'_a(\text{cool}) = \text{on}$ (active cooling). We can formally prove that this is not possible.

**Proposition 4.** Let $\hat{\text{Eng}}_g$ be the same as $\text{Eng}_g$, except for the evolution map, in which the real interval $[v_1, v_2]$ is given by $[-0.7 - \delta, -0.7 + \delta]$ if $\xi'_a(\text{cool}) = \text{on}$. Then, $\text{Eng}_g \not\approx \hat{\text{Eng}}_g$, for any $g \in \mathbb{N}^+$. 

The proof can be found in the Appendix, in Section A.2. Finally, we show how we can use the compositionality of our behavioural semantics (Theorem 2) to deal with bigger CPSs. Suppose that $\text{Eng}_g$ denotes the model in our calculus of an airplane engine. In this case, we could model a very simple airplane control system that checks whether the left engine ($\text{Eng}_g^l$) and the right engine ($\text{Eng}_g^r$) are signalling warnings. The whole CPS is defined as follows:

$$\text{Airplane}_g = (\ (\text{Eng}_g^l \uplus \text{Eng}_g^r) \parallel \text{Check} ) \setminus \{ \text{warning} \}$$

where $\text{Eng}_g^l = \text{Eng}_g^l \{ \text{temp} / \text{temp} \} \{ \text{cool} / \text{cool} \} \{ \alpha / \alpha \} \}$, and $\text{Eng}_g^r = \text{Eng}_g^r \{ \text{temp} / \text{temp} \} \{ \text{cool} / \text{cool} \} \{ \beta / \beta \} \}$, and process Check is defined as follows:

$$\begin{align*}
\text{Check} & = \text{recX}. [\text{rcv warning}(x). [x = L] \{ \text{Check}_1^l \}, \{ \text{Check}_1^r \} ] X \\
\text{Check}_1^l & = [ \text{rcv warning}(y). [y \neq id] \{ \text{snd alarm}. \text{tick}.X \}, \{ \text{tick}. \text{Check}_1^l \{ \text{Check}_1^r \} ] X \\
\text{Check}_1^r & = [ \text{rcv warning}(z). [z \neq id] \{ \text{snd alarm}. \text{tick}.X \}, \{ \text{snd failure}(id). \text{tick}.X \} ] \\
\text{snd failure}(id) & \mathrm{.} X 
\end{align*}$$

for $1 \leq i \leq 5$. Intuitively, if one of the two engines is in a warning state then the process $\text{Check}_i^d$, for $id \in \{ L, R \}$, checks whether also the second engine moves into a warning state, in the following 5 time intervals (i.e. during the cooling cycle). If both engines get in a warning state then an alarm is sent, otherwise, if only one engine is facing a warning then the airplane control system yields a failure signalling which engine is not working properly.

So, since we know that $\text{Eng}_g \approx \text{Eng}_g$, for any $g \in \mathbb{N}^+$, the final question becomes the following: can we safely equip our airplane with the more performant engines, $\text{Eng}_g^l$ and $\text{Eng}_g^r$, in which $[v_1, v_2] = [-0.8-\delta, -0.8+\delta]$, if $\xi'_g(cool) = \text{on}$, without affecting the whole observable behaviour of the airplane? The answer is “yes”, and this result can be formally proved by relying on Proposition 3 and Theorem 2.

**Proposition 5.** Let $\text{Airplane}_g = (\ (\text{Eng}_g^l \uplus \text{Eng}_g^r) \parallel \text{Check} ) \setminus \{ \text{warning} \}$. Then, $\text{Airplane}_g \approx \text{Airplane}_g$.

We end this section with an observation. Although, the engine $\text{Eng}_g$ is not behavioural equivalent to the original engine $\text{Eng}_g$, an airplane maker might be interested in knowing an estimation of the deviation of its behaviour with respect the behaviour of the original engine. If this deviation would be very small then aeronautical engineers might consider to adopt in their airplanes the engine $\text{Eng}_g$ instead $\text{Eng}_g$ to save even more coolant. So, the new question is: how big is the deviation, in terms of behaviour, of the engine $\text{Eng}_g$ with respect to the original engine $\text{Eng}_g$?

The rest of the paper is devoted to develop general quantitative techniques to estimate the deviation of the probabilistic behaviour of a CPS with respect to another.
5 Bisimulation metrics

In this section, we provide a weak behavioural distance to compare the probabilistic behaviour of CPSs up to a given approximation. To this end, we adapt the notion of weak bisimilarity metric \[27\] to pCCPS. Intuitively, we will write \(M \approx_p N\) if the weak bisimilarity between \(M\) and \(N\) holds with a distance \(p\), with \(p \in [0, 1]\). Thus, \(\approx_0\) will coincide with the weak probabilistic bisimilarity of [Definition 9] whereas \(\bigcup_{p \in [0,1]} \approx_p\) will correspond to the cartesian product pCCPS \(\times\) pCCPS.

Weak bisimilarity metric is defined as a pseudometric measuring the tolerance of the probabilistic weak bisimilarity.

**Definition 12 (Pseudometric).** A function \(d : \text{pCCPS} \times \text{pCCPS} \to [0, 1]\) is said to be a 1-bounded pseudometric if

- \(d(M, M) = 0\), for all \(M \in \text{pCCPS}\),
- \(d(M, M') = d(M', M)\), for all \(M, M' \in \text{pCCPS}\),
- \(d(M, M') \leq d(M, M'') + d(M'', M')\), for all \(M, M', M'' \in \text{pCCPS}\).

Weak bisimilarity metric provides the quantitative analogous of the weak bisimulation game: two CPSs \(M\) and \(N\) at distance \(p\) can mimic each other transitions and evolve to distributions \(\gamma\) and \(\gamma'\), respectively, placed at some distance \(q\), with \(q \leq p\). This requires to lift pseudometrics from CPSs to distributions over CPSs. To this end, as in [47], we rely on the notions of matching [61] and Kantorovich lifting [40].

In [Definition 8], we already provided the definition of matching. Let us define the Kantorovich lifting.

**Definition 13 (Kantorovich lifting).** Let \(d : \text{pCCPS} \times \text{pCCPS} \to [0, 1]\) be a pseudometric. The Kantorovich lifting of \(d\) is the function \(K(d) : \mathcal{D}(\text{pCCPS}) \times \mathcal{D}(\text{pCCPS}) \to [0, 1]\) defined as:

\[
K(d)(\gamma, \gamma') = \min_{\omega \in \Omega(\gamma, \gamma')} \sum_{M, M' \in \text{pCCPS}} \omega(M, M') \cdot d(M, M')
\]

for all \(\gamma, \gamma' \in \mathcal{D}(\text{pCCPS})\).

Note that since we are considering only distributions with finite support, the minimum over the set of matchings \(\Omega(\gamma, \gamma')\) is well defined.

**Definition 14 (Weak bisimulation metric).** We say that a pseudometric \(d : \text{pCCPS} \times \text{pCCPS} \to [0, 1]\) is a weak bisimulation metric if for all \(M, N \in \text{pCCPS}\), with \(d(M, N) < 1\), whenever \(M \overset{\Delta}{\rightarrow} \gamma\) there is a sub-distribution \(\gamma'\) such that \(N \overset{\Delta}{\rightarrow} \gamma'\) and \(K(d)(\gamma, \gamma' + (1 - |\gamma'|)|\text{Dead}) \leq d(M, N)\).

Note that in the previous definition, if \(|\gamma'| < 1\) then, with probability \(1 - |\gamma'|\), there is no way to simulate the behaviour of any CPS with a valid invariant in the support of \(\gamma\) (the special CPS Dead does not perform any action).

A crucial result is the existence of the minimal weak bisimulation metric \[27\], called weak bisimilarity metric, and denoted with \(d\). We remark that in [27] it is shown that the kernel of \(d\) coincides with the definition of weak probabilistic bisimilarity.

**Proposition 6.** For all \(M, N \in \text{pCCPS}\) we have \(d(M, N) = 0\) if and only if \(M \approx N\).

Now, we have all ingredients to define our notion of behavioural distance between CPSs.

\[\text{The original formulation of weak bisimulation metric [27] is technically different but equivalent to our definition [22].}\]
Definition 15 (Distance between CPSs). Let $M, N \in pCCPS$ and $p \in [0, 1]$. We say that $M$ and $N$ have distance $p$, written $M \approx_p N$, if and only if $d(M, N) = p$.

In the next section, we will use a more refined notion of distance that considers only the first $n \in \mathbb{N}$ computation steps, when comparing two CPSs.

Such definition requires the introduction of a complete lattice $([0, 1]^{pCCPS \times pCCPS}, \sqsubseteq)$ of functions of type $pCCPS \times pCCPS \to [0, 1]$ ordered by $d_1 \sqsubseteq d_2$ iff $d_1(M, N) \leq d_2(M, N)$ for all $M, N \in pCCPS$, where for each set $D \subseteq [0, 1]^{pCCPS \times pCCPS}$ the supremum and infimum are defined as $\sup(D)(M, N) = \sup_{d \in D} d(M, N)$ and $\inf(D)(M, N) = \inf_{d \in D} d(M, N)$, for all $M, N \in pCCPS$. Notice that the infimum of the lattice is the constant function zero, which we denote by $0$.

We also need a functional $\mathbf{B}$ defined over the lattice mentioned above such that $\mathbf{B}(d)(M, N)$ returns the minimum possible value for $d(M, N)$ in order to ensure that $d$ is a weak bisimulation metric.

Definition 16 (Bisimulation metric functional). Let $\mathbf{B} : [0, 1]^{pCCPS \times pCCPS} \to [0, 1]^{pCCPS \times pCCPS}$ be the functional such that for any $d \in [0, 1]^{pCCPS \times pCCPS}$ and $M, N \in pCCPS$, $\mathbf{B}(d)(M, N)$ is given by:

$$\sup_{\{\alpha : M \xrightarrow{\alpha} N\}} \max \left\{ \max \min K(d)(\gamma_1, \gamma_2 + (1 - |\gamma_2|)\text{Dead}), \min \max K(d)(\gamma_1 + (1 - |\gamma_1|)\text{Dead}, \gamma_2) \right\}$$

where $\max \emptyset = 0$ and $\min \emptyset = 1$.

Notice that Definition 16 and Definition 14 are strictly related as weak bisimulation metrics are pseudometrics that are prefixed points of $\mathbf{B}$. Notice also that all max and min in Definition 16 are well defined since our pLTS is image finite and CPSs enjoy the well timedness property.

Since $K$ is monotone, it follows that $\mathbf{B}$ is a monotone function on $([0, 1]^{pCCPS \times pCCPS}, \sqsubseteq)$. Furthermore, since this structure is a lattice, by Knaster-Tarski theorem it follows that $\mathbf{B}$ has a least prefixed point (which is also the least fixed point). Later we will show that this least prefixed point coincides with $d$.

Now, we exploit the functional $\mathbf{B}$ to introduce a notion of $n$-weak bisimilarity metric, denoted $d^n$, which intuitively quantifies the tolerance of the weak bisimulation in $n$ steps. The idea is that $d^0$ coincides with the constant function $0$ assigning distance $0$ to all pairs of CPSs, whereas $d^n(M, N)$, for $n > 0$, is defined as $d^n(M, N) = \mathbf{B}(d^{n-1})(M, N)$. Thus, the $n$-weak bisimilarity metric between $M$ and $N$ is defined in terms of the $(n-1)$-weak bisimilarity metric between the distributions reached (in one step) by $M$ and $N$, respectively.

Definition 17 ($n$-weak bisimilarity metric). Let $n \in \mathbb{N}$. The function $\mathbf{B}^n(0)$, abbreviated as $d^n$, is called $n$-weak bisimilarity metric.

Proposition 7. For all $n \geq 0$, $d^n$ is a $1$-bounded pseudometric.

The proof of this proposition can be found in Appendix, in Section A.3.

Finally, we are ready to define our notion of $n$-distance between two CPSs.

Definition 18 ($n$-distance between CPSs). Let $M, N \in pCCPS$ and $p \in [0, 1]$. We say that $M$ and $N$ have $n$-distance $p$, written $M \approx^n_p N$, if and only if $d^n(M, N) = p$.

Since our pLTS is image-finite, and all transitions lead to distributions with finite support, it is possible to prove that $\mathbf{B}$ is continuous. Since $\mathbf{B}$ is also monotone, we can deduce that the closure ordinal of $\mathbf{B}$ is $\omega$ (see Section 3 of [58]). As a consequence, the $n$-weak bisimilarity metrics converge to the weak bisimilarity metric when $n$ grows indefinitely. Formally,

Proposition 8. $d = \lim_{n \to \infty} d^n$. 
Last but not least, the distances introduced in [Definition 13] and [Definition 18] allow us to compare CPSs in a compositional manner. In particular, these distances are preserved by parallel composition of physical-disjoint CPSs, by parallel composition of pure-logical processes, and by channel restriction.

**Theorem 3** (Compositional distances). Let M and N be two arbitrary CPSs in pCCPS.

1. $M \approx_p N$ implies $M \parallel O \approx_q N \parallel O$, with $q \leq p$, for any physically-disjoint CPS O;
2. $M \approx_p N$ implies $M \parallel P \approx_q N \parallel P$, with $q \leq p$, for any pure-logical process P;
3. $M \approx_p N$ implies $M \setminus c \approx_q M \setminus c$, with $q \leq p$, for any channel c;
4. $M \approx^n_p N$ implies $M \parallel O \approx^n_q N \parallel O$, with $q \leq p$, for any physically-disjoint CPS O and any $n \geq 0$;
5. $M \approx^n_p N$ implies $M \parallel P \approx^n_q N \parallel P$, with $q \leq p$, for any pure-logical process P and any $n \geq 0$;
6. $M \approx^n_p N$ implies $M \setminus c \approx^n_q M \setminus c$, with $q \leq p$, for any channel c and $n \geq 0$.

The proof of Theorem 3 can be found in the Appendix, in Section A.3.

Now, suppose that $M \approx_p N$, $M' \approx_p N'$, with $M$ (resp. $N$) and $M'$ (resp. $N'$) physically-disjoint. By Theorem 11, we can infer both $M \parallel M' \approx_q N \parallel M'$ and $N \parallel M' \approx_q N \parallel N'$, with $q \leq p$ and $q' \leq p'$. Then, by triangular property of the pseudometric $d$ we get $M \parallel M' \approx_q N \parallel N'$, for some $q'' \leq q + q' \leq p + p'$. Similarly, by applying Theorem 4 we can infer that $M \parallel M' \approx_p N$ and $M' \approx_p N'$ entail $M \parallel M' \approx_p N \parallel N'$, for some $q \leq p + p'$. This says that our metrics enjoy a well-known compositional property called non-expansiveness [26, 32, 34].

In the next section, the compositional properties of Theorem 3 will be very useful when reasoning on our case study.

### 6 Case study, reloaded

In Section 4 we proved that the original version of the proposed engine, $\tilde{\text{Eng}}_g$, and its variant $\hat{\tilde{\text{Eng}}}_g$ (saving up to 10% of coolant) are behavioural equivalent (i.e., bisimilar). Then, by relying on the compositional property of our probabilistic bisimilarity (Theorem 2), we proved that the two compound systems, $\tilde{\text{Airplane}}_g$ and $\hat{\tilde{\text{Airplane}}}_g$, mounting engines $\tilde{\text{Eng}}_g$ and $\hat{\tilde{\text{Eng}}}_g$, respectively, are bisimilar as well.

Actually, both results can be proved in terms of weak probabilistic metric with distance 0, as this specific metric coincides with the probabilistic bisimilarity (Proposition 6).

**Proposition 9.** Let $g \in \mathbb{N}^+$. Then,

- $\tilde{\text{Eng}}_g \approx_0 \hat{\tilde{\text{Eng}}}_g$
- $\tilde{\text{Airplane}}_g \approx_0 \hat{\tilde{\text{Airplane}}}_g$.

Then, in Section 4 we moved our attention to a more performant engine, $\hat{\tilde{\text{Eng}}}_g$, saving almost 20% of coolant with respect to the original engine $\tilde{\text{Eng}}_g$. In our behavioural analysis we rejected this new variant as it may exhibit a different probabilistic behaviour when compared to $\tilde{\text{Eng}}_g$. More precisely, the two systems $\tilde{\text{Eng}}_g$ and $\hat{\tilde{\text{Eng}}}_g$ are not bisimilar (Proposition 5).

However, in many complex probabilistic systems, such as CPSs, probabilistic bisimilarity might reveal to be too strong as the natural behavioural equivalence to take systems apart. Thus, in Section 4 we advocated for some appropriate notion of behavioural distance to estimate the effective difference, in terms of behaviour, of these two versions of the engine.

In the current section, we apply the bisimulation metrics defined in Section 5 to estimate the distance between $\tilde{\text{Eng}}_g$ and $\hat{\tilde{\text{Eng}}}_g$, by varying the granularity $g \in \mathbb{N}^+$. In particular, we apply the notion of $n$-weak bisimilarity metric.
Proposition 10. Let \( g \in \mathbb{N}^+ \) and \( n \in \mathbb{N} \). Then, for \( p_g = \frac{[0.3, 0.4]}{[0.3, 1.1]} \) and \( q_g = \frac{[1.3, 1.4]}{[0.6, 1.4]} \), we have:

\[
\mathbf{d}^n(\mathbf{Eng}_g, \mathbf{Eng}_g) \leq 1 - (1 - q_g(p_g))^n .
\]

Note that if the cooling system of \( \mathbf{Eng}_g \) is off and it is not going to be activated in the current time slot, then the sensed temperature is below than or equal to 10, and the real temperature is below than or equal to 10.1 degrees (we recall that \( \text{err} = 0.1 \)). Assume that the temperature is exactly 10.1. If in the current time slot the temperature increases of a value \( v \in (1.3, 1.4) \) then it will reach a value in the interval \((11.4, 11.5)\) (we recall that \( \delta = 0.4 \)). This happens with a probability bounded by \( q_g \). In this case, the cooling system will be turned on, and the temperature will drop, in each of the following 5 time slots, of some value laying in the interval \([0.7 - \delta, 0.7 + \delta] = [0.3, 1.1]\). However, if in each of those 5 slots of cooling the temperature is decreased of a value laying in \([0.3, 0.4]\), then the cooling activity might not be enough to avoid (observable) warnings, and the two engines \( \mathbf{Eng}_g \) and \( \mathbf{Eng}_g \) will be distinguished. Thus, \( p_g \) is given by the number of possible “bad decreases”, \( |[0.3, 0.4]| \), divided by the number of all possible decreases, \( |[0.3, 1.1]| \); whereas \( q_g \) is given by the number of possible “bad increases”, \( |(1.3, 1.4)| \), divided by the number of all possible increases \( |(0.6, 1.4)| \).

Notice that \( p_g \) and \( q_g \) refer to real intervals which are basically shifted. Thus, we have that \( |[0.3, 0.4]| = |(1.3, 1.4)| = 10^{g-1} \) and \( |[0.3, 1.1]| = |[0.6, 1.4]| = 8 \cdot 10^{g-1} + 1 \). As a consequence, \( p_g = q_g = \frac{10^{g-1}}{8 \cdot 10^{g-1} + 1} \). Obviously, the finer is the granularity \( g \) the closer is the value of \( p_g \) and \( q_g \) to \( \frac{1}{8} \). Formally,

\[
\lim_{g \to \infty} \mathbf{d}^n(\mathbf{Eng}_g, \mathbf{Eng}_g) \leq 1 - (1 - \frac{1}{8})^n .
\]  

(1)

Thus, for instance, assuming a granularity \( g = 6 \), after \( n = 3000 \) computation steps the distance between the two systems is less than 0.012. Intuitively, this means that if we limit our analysis to 3000 computation steps the behaviours of two engines may differ with probability at most 0.012. By an easy inspection in the (common) logics of the two engines, it is easy to see that any two subsequent tick-actions are separated by at most 2 untimed actions. Thus, 3000 computation steps means around 1000 time slots. Considering time slots lasting 20 seconds each, this means more than five hours. Thus, an utilisation of \( \mathbf{Eng}_g \) might be feasible in airplanes used for short-range flights, where the engine is actually used for a limited amount of time. Actually, aeronautical engineers might consider perfectly acceptable the risk of mounting the engine \( \mathbf{Eng}_g \) instead of \( \mathbf{Eng}_g \), when compared to the reliability of the other components of the airplane.

However, since an airplane mounts two engines, engineers need to estimate the difference in terms of behaviour on the whole airplane resulting by the adoption of different versions of the engine. This is exactly the point where we can rely on Theorem 3 to support compositional reasoning.

The following result follows from Equation 1 Proposition 10 and Theorem 3.

Proposition 11. Let \( g \in \mathbb{N}^+ \) and \( n \in \mathbb{N} \). Let \( \mathbf{Airplane}_g = (\mathbf{Eng}_g \cup \mathbf{Eng}_g) \backslash \{\text{warning}\} \). Then,

1. \( \mathbf{d}^n(\mathbf{Airplane}_g, \mathbf{Airplane}_g) \leq 2p \), where \( p = 1 - (1 - q_g(p_g))^5 \)

2. \( \lim_{g \to \infty} \mathbf{d}^n(\mathbf{Airplane}_g, \mathbf{Airplane}_g) \leq 2(1 - (1 - \frac{1}{8})^n) \).

Thus, for \( g = 6 \), the probability that the two airplanes mounting different engines exhibit a different behaviour within \( n = 3000 \) computation steps is at most 0.024; a distance which may be considered still acceptable in specific contexts. Notice that in the (common) logics of the two airplanes, it is easy to see that two tick-actions are separated by at most 5 untimed actions (two for each engine plus one to signal a
Thus, 3000 computation steps means around 600 time slots, i.e., more than three hours for time slots lasting 20 second each.

Finally, the reader should notice that the bound of the distance between the two airplanes is given by the summation of the bounds of the distances between the two corresponding engines. This is perfectly in line with the fact that our bisimulation metrics enjoy the non-expansiveness property.

The proofs of the previous propositions can be found in the Appendix, in Section A.4.

7 Conclusions, related and future work

We have proposed a hybrid probabilistic process calculus, called pCCPS, for specifying and reasoning on cyber-physical systems. Our calculus allows us to model a CPS by specifying its physical plant, containing information on state variables, sensors, actuators, evolution law, etc., and its logics, i.e., controllers, IDSs, supervisors, etc. Physical and logical components interact through sensors and actuators, whereas interactions within the logics or between logics of different CPSs rely on channel-based communication. In pCCPS, the representation of the evolution map takes into account the uncertainty of the physical model, whereas the representation of the measurement map consider measurement errors in sensor reading. As a consequence, the two maps returns discrete probability distributions over state functions and sensor functions, respectively.

pCCPS is equipped with a probabilistic labelled transition semantics which satisfies classical time properties: time determinism, patience, maximal progress, and well-timedness. As behavioural semantics we adopt a natural notion of weak probabilistic bisimilarity which is proved to be preserved by appropriate system contexts that are suitable for compositional reasoning. Then, we argue that probabilistic bisimilarity is only partially satisfactory to reason on CPSs as it can only establish whether two CPSs behave exactly in the same way. To this end, we generalise our probabilistic bisimilarity to provide a notion of weak bisimulation metric along the lines of [27]. We also define a notion of weak bisimulation metric in n steps, which reveals to be very effective whenever it is not necessary to observe the system “ad infinitum” but it is enough to observe its behaviour restricted to bounded computations. Again, both bisimulation metrics are proved to be suitable for compositional reasonings. The paper provides a case study, taken from an engineering application, and use it to illustrate our definitions and our compositional probabilistic behavioural theory for pCCPS.

Related work. A number of approaches have been proposed for modelling hybrid systems using formal methods. For instance, hybrid automata [3] combine finite state transition systems (to model the cyber component) and continuous variables and dynamic (to represent the physical component). A number of hybrid process algebras [18, 7, 57, 54, 30] have been proposed for reasoning about physical systems and provide techniques for analysing and verifying protocols for hybrid automata. Among these approaches, pCCPS shares some similarities with the φ-calculus [54], a hybrid extension of the π-calculus [50] equipped with a weak bisimilarity that is not compositional. Galpin et al. [30] proposed a process algebra, called HYPE, in which the continuous part of the system is represented by appropriate variables whose changes are determined by active influences (i.e., commands on actuators). The authors define a strong bisimulation that extends the ic-bisimulation of [7]. Unlike ic-bisimulation, the bisimulation in HYPE is preserved by a notion of parallel composition that is slightly more permissive than ours. However, bisimilar systems in HYPE must always have the same influence. Thus, in HYPE we cannot compare CPSs sending different commands on actuators at the same time, as we do (for instance) in Proposition 3.

In order to enrich hybrid models with probabilistic or stochastic behaviour, a number of different approaches have been proposed in the last years [56, 39, 12, 2, 29, 56, 62]. Most of these approaches
consist in introducing either probabilities in the transitions relation, or probabilistic choice, or stochastic differential equations. For instance, in Stochastic Hybrid CSP (SHCSP) [62] probabilistic choice replaces non-deterministic choice, stochastic differential equations replace differential equations, and communication interrupts are generalised by communication interrupts with weights.

The formal analysis of probabilistic and stochastic systems follows the two classic mainstreams: (i) model checking (e.g., [2]) and reachability (e.g., [55, 2]), when the focus is on a single system; behavioural equivalences (e.g., [48, 55, 53, 5, 4, 13]) when the goal is to compare the behaviour of two systems (very often, specification and implementation of the same system). As already said in the Introduction, probabilistic behavioural equivalences may be too strong in certain probabilistic and stochastic models in which many interesting systems are only approximately behavioural equivalent. This led to several notions of behavioural distance that can be grouped in two main families: quantitative counterparts of trace equivalence [16, 28, 19, 63], and quantitative counterparts of bisimulation equivalence [27, 26, 59, 21]. We refer to [1, 9] for a comparison between these two approaches. In the present paper, we have adopted a bisimulation-based definition because, unlike trace semantics, bisimulation is sensitive to system deadlock, a phenomenon that has a great impact in CPSs.

Vigo et al. [60] proposed a calculus for wireless-based cyber-physical systems endowed with a theory to study cryptographic primitives, together with explicit notions of communication failure and unwanted communication. The calculus does not provide any notion of behavioural equivalence. It also lacks a clear distinction between physical and logical components.

Lanese et al. [43] proposed an untimed calculus of mobile IoT devices interacting with the physical environment by means of sensors and actuators. The calculus does not allow any representation of the physical environment, and it is equipped with an end-user bisimilarity in which end-users may: (i) provide values to sensors, (ii) check actuators, and (iii) observe the mobility of smart devices. End-user bisimilarity is not preserved by parallel composition. Compositionality is recovered by strengthening its discriminating power.

Lanotte and Merro [45] extended and generalised the work of [43] in a timed setting by providing a bisimulation-based semantic theory that is suitable for compositional reasoning. As in [43], the physical environment is not represented.

Bodei et al. [10, 11] have proposed a new untimed process calculus, IoT-LYSA, supporting a control flow analysis that safely approximates the abstract behaviour of IoT systems. Essentially, they track how data spread from sensors to the logics of the network, and how physical data are manipulated. Intra-node generative communications in IoT-LYSA are implemented through a shared store à la Linda [35]. In this manner physical data are made available to software entities that analyse them and trigger the relevant actuators to perform the desired behaviour. The calculus adopt asynchronous multi-party communication among nodes taking care of node proximity (the topology is static). The dynamics of the calculus is given in terms of a reduction relation. No behavioural equivalences are defined.

Finally, the paper at hand extends the conference paper [44] in the following aspects: (i) the calculus has become a probabilistic calculus, both in its logical and its physical components; the logics has been enriched with probabilistic choice, whereas discrete (finite-support) probability distributions have replaced continuous non-deterministic uncertainties in the evolution and continuous non-deterministic error-prone measurements; (ii) standard bisimulation has been replaced with probabilistic bisimulation and then with bisimulation metrics; (iii) as a consequence, the case study has been revisited using our bisimulation metrics to estimate the deviation in terms of behaviour of the systems under investigation.

Future work. We believe that our paper can lay and streamline theoretical foundations for the development of formal and automated tools to verify CPSs before their practical implementation. To that end, we
will consider applying, possibly after proper enhancements, existing tools and frameworks for automated verification, such as Maude \[51\], PRISM \[42\], SMC UPPAAL \[20\] and Ariadne \[6\], resorting to the development of a dedicated tool if existing ones prove not up to the task. Finally, in \[46\], we are currently working on a non-probabilistic version of pCCPS extended with security features to provide a formal study of a variety of cyber-physical attacks targeting physical devices. In this case, the final goal is to develop formal and automated tools to analyse security properties of CPSs.

As possible future work, a non-trivial challenge would be to extend the present work in order to deal with continuous probability distributions. In our setting, this would mean, for instance, that the evolution map $\text{evol}$ should return a continuous distribution over state functions, and that the function $\text{next}_E(S)$ should return a continuous distributions over physical states. However, this would immediately give rise to a serious technical problem: the definition of probabilistic weak labelled transitions, and hence the definition of weak behavioural equivalences and distances. To better illustrate the problem, suppose to adopt continuous probability distributions in our calculus, and suppose a cyber-physical system $M$ such that $M \xrightarrow{\text{tick}} \gamma$, for some continuous probability distribution $\gamma$ over CPSs. Suppose $\gamma$ is a uniform distribution such that $\text{supp}(\gamma) = \{ M_r : r \in [0, 1] \}$, with $M_r \neq M_r'$, for any $r \neq r'$. Independently on the specific definition of the CPSs $M_r$, as the logics of any CPS is intrinsically discrete, the cyber-component of any $M_r$ will drive the whole system to a discrete distribution. As an example, assume a cyber-physical system $N$ such that for all reals $r \in [0, 0.5]$ there is a $\tau$-transition $M_r \xrightarrow{\tau} N$; whereas for all reals $r \in (0.5, 1]$ there is a $\tau$-transition $M_r \xrightarrow{\tau} M_r'$. In such a situation, it is far from obvious to determine what should be the distribution $\gamma_m$ reached by the original CPS $M$ after a weak tick-transition, $M \xrightarrow{\text{tick}} \gamma_m$. In fact, $\gamma_m$ can be neither a discrete nor a continuous distribution. This because $\gamma_m$ should map $N$ to a probability weight $0.5$ (as in a discrete distribution), and then it should distribute the remaining mass probability as a uniform (sub-)distribution to all $M_r$ with $r \in (0.5, 1]$, such that $\int_{0.5}^{1} \gamma_m(M_r) \, dt = 0.5$ (as in a continuous distribution).

A possible solution to capture weak transitions when working with continuous probability distributions is to approximate them via discrete ones by adopting the approach proposed for labelled Markov processes in \[25\] \[26\]. In these papers, Desharnais et al. propose approximation techniques for continuous-state labelled Markov processes $\mathcal{S}$ in terms of finite-state Markov chains $\mathcal{S}(n, \varepsilon)$, parametric in a natural number $n$ and a rational number $\varepsilon > 0$. Here, $n$ is the maximal number of possible consecutive transitions from the start state of $\mathcal{S}(n, \varepsilon)$ (the idea being that this Markov chain is the $n$-steps unfolding of the original Markov process $\mathcal{S}$), whereas the rational number $\varepsilon > 0$ measures the accuracy of probabilities in $\mathcal{S}(n, \varepsilon)$ when approximating the transitions of the original process $\mathcal{S}$. In their Theorem 4.4 \[25\] the authors prove that if a state $s$ of $\mathcal{S}$ satisfies a formula in the logic characterising probabilistic bisimulation then there is some approximation $\mathcal{S}(n, \varepsilon)$ satisfying exactly the same formula. Furthermore, the same authors show that one can always reconstruct the original process from the approximations. More precisely, a Markov process bisimilar to the original one can always be derived from the countable approximates $\mathcal{S}(n, 2^{-n})$, for some $n \in \mathbb{N}$ (in the current paper we adopted a granularity $\varepsilon = 10^{-n}$). Actually, they do not reconstruct the original state space, but they reconstruct all the transition probability information, i.e., the dynamical aspects of the process (see Theorem 4.5 of \[25\]).

Acknowledgements. We thank the anonymous reviewers for their insightful and careful reviews.

A Probabilistic Calculus of Cyber-Physical Systems

A.1 Proofs of Section 2

Theorem 1 states that CPSs enjoy time determinism, maximal progress, patience and well-timedness. We start with showing that processes enjoy the same properties.

Lemma 1 (Processes time properties). Assume a process $P$.

(a) If $P \xrightarrow{\text{tick}} \pi$ and $P \xrightarrow{\text{tick}} \pi'$, then $\pi \equiv \pi'$.

(b) If $P \xrightarrow{\tau} \pi$ then there is no $\pi'$ such that $P \xrightarrow{\text{tick}} \pi'$.

(c) If $P \xrightarrow{\text{tick}} \pi'$ for no $\pi'$ then there is $\pi$ such that $P \xrightarrow{\lambda} \pi$ for some $\lambda \in \{\tau, a!v, s?x\}$.

(d) There is a $k \in \mathbb{N}$ such that if $P \xrightarrow{\lambda_1} \cdots \xrightarrow{\lambda_n} P'$, with $\lambda_i \neq \text{tick}$, then $n \leq k$.

Proof. We show the four properties separately.

(a) The proof is by induction on the depth $d$ of the derivation tree allowing us to derive $P \xrightarrow{\text{tick}} \pi$.

Base case $d = 1$. The transition $P \xrightarrow{\text{tick}} \pi$ is derived by applying one of the rules (TimeNil), (Delay) and (Timeout), and the thesis is immediate.

Inductive step $d > 1$. The transition $P \xrightarrow{\text{tick}} \pi$ is derived by applying one of the rules (TimePar), (ChnRes) and (Rec). We consider the case (TimePar), the others are similar. Since $P \xrightarrow{\text{tick}} \pi$ is derived by rule (TimePar), process $P$ must be of the form $P \equiv P_1 \parallel P_2$ for suitable processes $P_1$ and $P_2$. Therefore also the rule $P \xrightarrow{\text{tick}} \pi'$ is derived through rule (TimePar). We have

- $P_1 \xrightarrow{\text{tick}} \pi_1, P_2 \xrightarrow{\text{tick}} \pi_2, P \xrightarrow{\tau} P_1 \parallel P_2 \xrightarrow{\tau}$
- $P_1 \parallel P_2 \xrightarrow{\text{tick}} \pi_1 \parallel \pi_2$

with $\pi = \pi_1 \parallel \pi_2$ and $\pi' = \pi_1' \parallel \pi_2'$.

By the inductive hypothesis we have that $\pi_1 \equiv \pi_1'$ and $\pi_2 \equiv \pi_2'$, which gives $\pi_1 \parallel \pi_2 \equiv \pi_1' \parallel \pi_2'$ and concludes the proof.

(b) The proof is by induction on the depth $d$ of the derivation tree allowing us to derive $P \xrightarrow{\tau} \pi$.

Base case $d = 1$. There is no rule in Table 1 allowing us to derive transition $P \xrightarrow{\tau} \pi$ with depth 1, hence the thesis follows trivially.

Inductive step $d > 1$. The transition $P \xrightarrow{\tau} \pi$ is derived by applying one of the rules (Com), (Par), (ChnRes) and (Rec). We consider the case (Com). Since $P \xrightarrow{\tau} \pi$ is derived by rule (Com), process $P$ must be of the form $P \equiv P_1 \parallel P_2$ for suitable processes $P_1$ and $P_2$. To show the thesis that no transition from $P_1 \parallel P_2$ labelled tick can be derived, it is enough to note that the only rule in Table 1 which may be applied to infer any tick-labelled transition from $P_1 \parallel P_2$ is rule (TimePar), which cannot be applied since it has $P_1 \parallel P_2 \xrightarrow{\tau}$ among its premises.

The other cases follow directly by induction.

(c) First of all we notice that, if $P = \text{rec} X.Q$, then, since $P$ is bounded and has time-guarded recursion, by applying repetitively the structural congruence $\text{rec} X.Q \equiv Q[\text{rec} X.Q/X]$, we find a process $P' \equiv P$ such that $P' \neq \text{rec} Y.R$, for any $Y$ and $R$. Since $P' \equiv P$ implies $P' \xrightarrow{\lambda}$ iff $P \xrightarrow{\lambda}$, for any $\lambda$, we can prove the thesis by structural induction on $P$ where $P$ is not of the form $P = \text{rec} X.Q$.

The base cases $P = \text{nil}$, $P = \text{tick}.C$ and $P = |\text{chn}.C|D$ are immediate since in all these cases a transition labelled tick from $P$ can be derived. The base case $P = \text{phy}.C$ holds since we can apply either rule (Write) to derive a transition from $P$ labelled $a!v$, or rule (Read) to derive a transition labelled $s?(x)$.

The inductive steps are $P = P_1 \parallel P_2$, $P = [b]P_1, \{P_2\}$ and $P = Q\setminus c$. Consider the case $P = P_1 \parallel P_2$. If no transition from $P_1 \parallel P_2$ labelled tick can be derived, then rule (TimePar) cannot be applied. Then, at least one of the premises $P_1 \xrightarrow{\text{tick}} \pi_1, P_2 \xrightarrow{\text{tick}} \pi_2$ and $P_1 \parallel P_2 \xrightarrow{\tau}$ does not hold. If $P_1 \xrightarrow{\text{tick}} \pi_1$ does not hold, then by the inductive hypothesis we have $P_1 \xrightarrow{\lambda} \pi_1$ for some $\lambda \in \{\tau, a!v, s?(x)\}$, and by rule (Par) we infer $P_1 \parallel P_2 \xrightarrow{\lambda} \pi_1 \parallel \pi_2$, which gives the thesis. If $P_2 \xrightarrow{\text{tick}} \pi_2$ does not hold,
then by the inductive hypothesis we have \( P_2 \xrightarrow{\lambda} \pi_2 \) for some \( \lambda \in \{ \tau, a_l v, s?_i(x) \} \), and by the rule symmetric to (Par) we infer \( P \parallel P_2 \xrightarrow{\lambda} P_1 \parallel \pi_2 \), which gives the thesis. If \( P \parallel P_2 \xrightarrow{\tau} \) does not hold then there is some transition \( P_1 \parallel P_2 \xrightarrow{\tau} \pi \), which gives the thesis. The cases \( P = [b] \{P_1\}, \{P_2\} \) and \( P = Q \setminus c \) are similar.

(d) The well-timedness property is straightforward from time-guardedness recursion.

The challenge in the proof of [Theorem 1] is to lift the results of [Lemma 1] to the CPSs of pCCPS.

**Proof of [Theorem 1]**

(a) We note that transitions labelled tick can be derived only by rule (Time). Therefore, from the hypothesis \( M \xrightarrow{\text{tick}} \gamma \) and \( M \xrightarrow{\text{tick}} \gamma' \) with \( M = E; S \bowtie P \), we infer that there are process distributions \( \pi \) and \( \pi' \) such that

\[
P \xrightarrow{\text{tick}} \pi \quad S \bowtie P \xrightarrow{\tau} S \in \text{inv} \quad \text{and} \quad P \xrightarrow{\text{tick}} \pi' \quad S \bowtie P \xrightarrow{\tau} S \in \text{inv}
\]

where \( \gamma = E; \text{next}_E(S) \bowtie \pi \) and \( \gamma' = E; \text{next}_E(S) \bowtie \pi' \). By the property of time determinism for processes in [Lemma 1] we infer that \( P \xrightarrow{\text{tick}} \pi \) and \( P \xrightarrow{\text{tick}} \pi' \) imply \( \pi \equiv \pi' \), hence \( \gamma \equiv \gamma' \), which completes the proof.

(b) From the hypothesis \( M \xrightarrow{\tau} \gamma \) with \( M = E; S \bowtie P \), we infer that \( \gamma = E; \sigma \bowtie \pi \) for distributions \( \sigma \) and \( \pi \) such that \( S \bowtie P \xrightarrow{\tau} \sigma \bowtie \pi \) is derived from the rules in [Table 2]. To show the thesis that no transition from \( M \) labelled tick can be derived, it is enough to show that no transition from \( S \bowtie P \) labelled tick can be derived from the rules in [Table 2]. This follows by the fact that the only rule which may be applied to infer any tick-labelled transition from \( S \bowtie P \) is rule (Time), which cannot be applied since it has \( S \bowtie P \xrightarrow{\tau} \) among its premises.

(c) From the hypothesis that \( M \xrightarrow{\text{tick}} \gamma \) with \( M = E; S \bowtie P \) cannot be inferred for any distribution \( \gamma \), we infer that \( S \bowtie P \xrightarrow{\text{tick}} \sigma \bowtie \pi \) cannot be derived for any \( \sigma \) and \( \pi \) from the rules in [Table 2]. Therefore, at least one of the premises \( P \xrightarrow{\text{tick}} \pi, S \bowtie P \xrightarrow{\tau} S \bowtie \pi' \) and \( S \in \text{inv} \) of rule (Time) does not hold. If premise \( P \xrightarrow{\text{tick}} \pi \) does not hold for any \( \pi \), then by the property of patience for processes in [Lemma 1] we have \( P \xrightarrow{\lambda} \pi' \) for some \( \pi' \) and \( \lambda \in \{ \tau, a_l v, s?_i(x) \} \). Let us consider the case \( \lambda = \tau \). From \( P \xrightarrow{\tau} \pi' \), either \( S \in \text{inv} \) is not valid, or we can apply rule (Tau) to infer the transition \( S \bowtie P \xrightarrow{\tau} S \bowtie \pi' \), which gives \( M \xrightarrow{\tau} E; S \bowtie \pi' \). In both cases the thesis holds. The cases \( \lambda \in \{ a_l v, s?_i(x) \} \) can be proved similarly by using rules (ActWrite) and (SensRead), respectively. If premise \( P \xrightarrow{\text{tick}} \pi \) holds for some \( \pi \) then either premises \( S \in \text{inv} \) or premise \( S \bowtie P \xrightarrow{\tau} \) does not hold. In the former case the thesis follows. In the latter case we have a \( \tau \)-labelled transition from \( M \) and the thesis holds as well.

(d) The proof is by contradiction. Suppose there is no \( k \) satisfying the statement of the thesis. Hence there exists an unbounded derivation

\[
E; S \bowtie P = E; S_1 \bowtie P_1 \xrightarrow{\alpha_1} \cdots \xrightarrow{\alpha_k} E; S_n \bowtie P_n \xrightarrow{\alpha_{k+1}} \cdots
\]
with \( a_i \neq \text{tick} \) for \( i \geq 1 \), namely there exist distributions \( \sigma_i \propto \pi_i \) for \( i \geq 1 \) with \( \sigma_i \propto P_i \stackrel{\alpha_i}{\longrightarrow} \sigma_{i+1} \propto \pi_{i+1} \), \( S_{i+1} \in \text{supp}(\sigma_{i+1}) \) and \( P_{i+1} \in \text{supp}(\pi_{i+1}) \). This contradicts the property of well-timedness for processes in Lemma 1.

\[ \square \]

### A.2 Proofs of Section 4

In order to prove Proposition 1 and Proposition 2 we use the following lemma that formalises the invariant properties binding the state variable \( \text{temp} \) with the activity of the cooling system. Intuitively, when the cooling system is inactive then the value of the state variable \( \text{temp} \) lays in the interval \([0,11+\text{err}+\delta]\).

Furthermore, if the coolant is not active and the variable \( \text{temp} \) lays in the interval \((10+\text{err},11+\text{err}+\delta]\) then the cooling will be turned on in the next time slot. Finally, if the cooling system is active then there is some \( k = 1 \ldots 5 \) such that the system was activated \( k \) time units ago, it was kept active so far and the state variable \( \text{temp} \) lays in the real interval \((10-\text{err}-k*(1+\delta),11+\text{err}+\delta-k*(1-\delta)]\).

**Lemma 2.** Let \( \text{Eng}_g \) be the system defined in Section 4

\[
\text{Eng}_g = M_1 \xrightarrow{t_1} \text{tick} M_2 \xrightarrow{t_2} \text{tick} \cdots \xrightarrow{t_{n-1}} \text{tick} M_n
\]

such that the traces \( t_j \) contain no tick-actions, for any \( j = 1 \ldots n-1 \), and for any \( i \in 1 \ldots n \) we have \( M_i = \text{Eng}_g \cup S_i \propto P_i \) with \( S_i = \langle \xi_1^i, \xi_k^i, \xi_{k+1}^i \rangle \) and \( \text{Eng}_g = \langle \text{evol}, \text{meas}, \text{inv} \rangle \). Then, for any \( i \in 1 \ldots n-1 \) we have the following:

1. if \( \xi_{1}^{i}(\text{cool}) = \text{off} \) then \( \xi_{k}^{i}(\text{temp}) \in [0,11+\text{err}+\delta] \);
2. if \( \xi_{1}^{i}(\text{cool}) = \text{off} \) and \( \xi_{k}^{i}(\text{temp}) \in (10+\text{err},11+\text{err}+\delta] \) then, in the next time slot, \( \xi_{k+1}^{i}(\text{cool}) = \text{on} \);
3. if \( \xi_{1}^{i}(\text{cool}) = \text{on} \) then \( \xi_{k}^{i}(\text{temp}) \in (10-\text{err}-k*(1+\delta),11+\text{err}+\delta-k*(1-\delta)] \), for some \( k = 1 \ldots 5 \) such that \( \xi_{k}^{i}(\text{cool}) = \text{off} \) and \( \xi_{k+1}^{i}(\text{cool}) = \text{on} \), for all \( j = 0 \ldots k-1 \).

**Proof.** Let us denote with \( v_i \) the values of the state variable \( \text{temp} \) in the systems \( M_i \), i.e., \( \xi_{k}^{i}(\text{temp}) = v_i \). Moreover we will say that the coolant is active (resp., is not active) in \( M_i \) if \( \xi_{k}^{i}(\text{cool}) = \text{on} \) (resp., \( \xi_{k}^{i}(\text{cool}) = \text{off} \)).

The proof is by mathematical induction on \( n \), i.e., the number of tick-actions of our traces.

The case base \( n = 1 \) follows directly from the definition of \( \text{Eng}_g \). Let prove the inductive case. We assume that the three statements holds for \( n = 1 \) and we prove that they also hold for \( n \).

1. Let us assume that the coolant is not active in \( M_{n} \), then we prove that \( v_{n} \in [0,11+\text{err}+\delta] \). We consider separately the cases in which the coolant is active or not in \( M_{n-1} \).

   • Suppose the coolant is not active in \( M_{n-1} \) (and inactive in \( M_{n} \)). By the inductive hypothesis we have \( v_{n-1} \in [0,11+\text{err}+\delta] \). Since we know that in \( M_{n} \) the cooling is not active, it follows that \( v_{n-1} \in [0,10+\text{err}] \), the reason being that \( v_{n-1} \in (10+\text{err},11+\epsilon+\delta] \) and the inductive hypothesis would imply that the coolant is active in \( M_{n} \). Furthermore, in \( M_{n} \) the temperature will increase of a value laying in the interval \([1-\delta,1+\delta] \) = \([0.6,1.4] \). Thus \( v_{n} \) will be in \([0.6,11+\text{err}+\delta] \subseteq [0,11+\text{err}+\delta] \).

   • Suppose the coolant is active in \( M_{n-1} \) (and active in \( M_{n} \)). By the inductive hypothesis we have \( v_{n-1} \in (10-\text{err}-k*(1+\delta),11+\text{err}+\delta-k*(1-\delta)] \) for some \( k = 1 \ldots 5 \) such that the coolant is not active in \( M_{n-1-k} \) and is active in all \( M_{n-k}, \ldots, M_{n-1} \).
The case $k \in \{1, \ldots, 4\}$ is not admissible, the reason being that $k \in \{1, \ldots, 4\}$ together with the fact that the coolant is inactive in $M_n$ would imply that the coolant has been kept active for less than 5 steps, which cannot happen.

Hence it must be $k = 5$. Since $\delta = 0.4$, $err = 0.1$ and $k = 5$, it holds that $v_{n-1} \in (10 - 0.1 - 5*1.4, 11 + 0.4 - 5*0.6] = (2.8, 8.6]$. Moreover, since the coolant is active for 5 tick actions, the controller of $M_{n-1}$ checks the temperature. However, since $v_{n-1} \in (2.8, 8.6]$ then the coolant is turned off. Thus, in the next time slot, the temperature will increase of a value in $[1 - \delta, 1 + \delta] = [0.6, 1.4]$. As a consequence in $M_n$ we will have $v_n \in [2.8 + 0, 6, 8.6 + 1.4] = [3.4, 10] \subseteq [0, 11 + err + \delta]$. 

2. Let us assume that the coolant is not active in $M_n$ and $v_n \in (10 + err, 11 + err + \delta]$, then we prove that the coolant is active in $M_{n+1}$. Since the coolant is not active in $M_n$ then it will check the temperature before the next time slot. Since $v_n \in (10 + err, 11 + err + \delta]$ and $err = 0.1$, then the process $Ctrl$ will sense a temperature greater than 10 and the coolant will be turned on. Thus the coolant will be active in $M_{n+1}$.

3. Let us assume that the coolant is active in $M_n$, then we prove that $v_n \in (10 - err - k*(1 + \delta), 11 + err + \delta - k*(1 - \delta)]$ for some $k \in 1 \ldots 5$ and the coolant is not active in $M_{n-k}$ and active in all $M_{n-k+1}, \ldots, M_n$.

We separate the case in which the coolant is active in $M_{n-1}$ from that in which is not active.

- Suppose the coolant is not active in $M_{n-1}$ (and active in $M_n$).
  
  In this case $k = 1$ as the coolant is not active in $M_{n-1}$ and it is active in $M_n$. Since $k = 1$, we have to prove $v_n \in (10 - err - (1 + \delta), 11 + err + \delta - (1 - \delta)]$.

  However, since the coolant is not active in $M_{n-1}$ and is active in $M_n$ it means that the coolant has been switched on in $M_{n-1}$ because the sensed temperature was above 10 (this may happen only if $v_{n-1} > 10 - err$). By inductive hypothesis, since the coolant is not active in $M_{n-1}$, we have that $v_{n-1} \in [0, 11 + err + \delta]$. Therefore, from $v_{n-1} > 10 - err$ and $v_{n-1} \in [0, 11 + err + \delta]$ it follows that $v_{n-1} \in (10 - err, 11 + err + \delta]$. Furthermore, since the coolant is active in $M_n$, the temperature will decrease of a value in $[1 - \delta, 1 + \delta]$ and therefore $v_n \in (10 - err - (1 + \delta), 11 + err + \delta - (1 - \delta)]$ which concludes this case of the proof.

- Suppose the coolant is active in $M_{n-1}$ (and active in $M_n$ as well).

  By inductive hypothesis there is $h \in 1 \ldots 5$ such that $v_{n-1} \in (10 - err - h*(1 + \delta), 11 + err + \delta - h*(1 - \delta)]$ and the coolant is not active in $M_{n-1-h}$ and is active in $M_{n-h}, \ldots, M_{n-1}$.

  The case $h = 5$ is not admissible. In fact, since $\delta = 0.4$ and $err = 0.1$, if $h = 5$ then $v_{n-1} \in (10 - 0.1 - 5*1.4, 11 + 0.1 + \delta - 5*0.6] = (2.8, 8.6]$. Furthermore, since the coolant is already active since 5 tick actions, the controller of $M_{n-1}$ is supposed to check the temperature. As $v_{n-1} \in (2.8, 8.6]$ the coolant should be turned off. In contradiction with the the fact that the coolant is active in $M_n$.

  Hence it must be $h \in 1 \ldots 4$. Let us prove that for $k = h + 1$ we obtain our result. Namely we have to prove that, for $k = h + 1$, (i) $v_n \in (10 - err - k*(1 + \delta), 11 + err + \delta - k*(1 - \delta)]$, and (ii) the coolant is not active in $M_{n-k}$ and active in all $M_{n-k+1}, \ldots, M_n$.

  Let us prove the statement (i). By inductive hypotheses, it holds that $v_{n-1} \in (10 - err - h*(1 + \delta), 11 + err + \delta - h*(1 - \delta)]$. Since the coolant is active in $M_n$ then the temperature will decrease. Hence, $v_n \in (10 - err - (h+1)*(1 + \delta), 11 + err + \delta - (h+1)*(1 - \delta)]$. Therefore, since $k = h + 1$, we have that $v_n \in (10 - err - k*(1 + \delta), 11 + err + \delta - k*(1 - \delta)]$.

  Let us prove the statement (ii). By inductive hypothesis the coolant is inactive in $M_{n-1-h}$ and it is active in all $M_{n-h}, \ldots, M_{n-1}$. Now, since the coolant is active in $M_n$, for $k = h + 1$, we
have that the coolant is not active in \( M_{n-k} \) and is active in all \( M_{n-k+1}, \ldots, M_n \) which concludes this case of the proof.

\[
\begin{array}{c}
\text{Proof of Proposition 1} \\
\text{By the first two items of Lemma 2 and since } \delta = 0.4 \text{ and } err = 0.1, \text{ we infer that the value of the state variable } temp \text{ is always in the real interval } [0, 11.5]. \text{ As a consequence, the invariant of the system is never violated and the system never deadlocks. Then, the last item of Lemma 2 ensures that after 5 tick-actions happening when the coolant is active, the state variable } temp \text{ is always in the real interval } (10 − 0.1 − 5 \times 1.4, 11 + 0.1 + 0.4 − 5 \times 0.6) = (2.9, 8.5). \text{ Hence the process Ctrl will never transmit on the channel warning.}
\end{array}
\]

\[
\begin{array}{c}
\text{Proof of Proposition 2} \\
\text{Let us prove the two statements separately.}
\begin{itemize}
\item If process Ctrl senses a temperature above 10 (and hence Eng turns on the cooling) then the value of the state variable temp is greater than 10 − err. By Lemma 2 the value of the state variable temp is always less or equal than 11 + err + δ. Therefore, if Ctrl senses a temperature above 10, then the value of the state variable temp is in (10 − err, 11 + err + δ] = (9.9, 11.5].
\item By Lemma 2 (third item) the coolant can be active for no more than 5 time slots. Hence, by Lemma 2 when Eng turns off the cooling system the state variable temp ranges over (10 − err − 5 \times (1 + δ), 11 + err + δ − 5 \times (1 − δ)] = (2.9, 8.5].
\end{itemize}
\end{array}
\]

\[
\begin{array}{c}
\text{Proof of Proposition 4} \\
\text{It is is enough to prove that there exists an execution trace of the engine } \hat{\text{Eng}}_g, \text{ containing an output along channel warning. Then the result follows by an application of Proposition 1.}
\end{array}
\]

\[
\begin{array}{c}
\text{We prove the thesis for } g = 1. \text{ Indeed a trace of } \hat{\text{Eng}}_g \text{ with } g = 1 \text{ is a trace of } \hat{\text{Eng}}_{g'} \text{ with } g' \geq g.
\end{array}
\]

\[
\begin{array}{c}
\text{We can easily build up a trace for } \hat{\text{Eng}}_g \text{ with } g = 1 \text{ in which, after 10 tick-actions, in the 11-th time slot, the value of the state variable temp is 10.1. In fact, it is enough to increase the temperature of 1 degree for the first 9 rounds and an increase of 1.1 degrees in the 10-th time slot. Notice that these are admissible values, since both 1 and 1.1 are in } [1 − δ, 1 + δ]_g = [0.6, 1.4]_g \text{ with } g = 1. \text{ Being 10.1 the value of the state variable temp, there is an execution trace in which the sensed temperature is 10 (recall that err = 0.1 and } −0.1 \in [−0.1, 0.1]_g \text{ with } g = 1) \text{ and hence the cooling system is not activated. However, in the following time slot, i.e.
\end{array}
\]

\[
\begin{array}{c}
\text{A.3 Proofs of Section 5}
\end{array}
\]

\[
\begin{array}{c}
\text{To prove that all } d^p \text{ are } 1\text{-bounded pseudometrics (Proposition 7), we need some preliminary results. First we show that the Kantorovich functional } K \text{ maps pseudometrics to pseudometrics.}
\end{array}
\]

\[
\begin{array}{c}
\text{Proposition 12. If } d : pCCPS \times pCCPS \rightarrow [0, 1] \text{ is a } 1\text{-bounded pseudometric, then also } K(d) : \mathcal{D}(pCCPS) \times \mathcal{D}(pCCPS) \text{ is a } 1\text{-bounded pseudometric.}
\end{array}
\]
Proof. To show $K(d)(\gamma, \gamma) = 0$ for all $\gamma \in \mathcal{D}(pCCPS)$ it is enough to take the matching $\omega \in \Omega(\gamma, \gamma)$ defined by $\omega(M, M) = \gamma(M)$, for all $M \in pCCPS$, and $\omega(M, N) = 0$, for all $M, N \in pCCPS$ with $M \neq N$. In fact, we have $K(d)(\gamma, \gamma) = \sum_{M,N \in pCCPS} \omega(M,N) \cdot d(M,N) = \sum_{M \in pCCPS} \gamma(M) \cdot d(M,M) = 0$.

The symmetry of $K(d)(\gamma, \gamma') = K(d)(\gamma', \gamma)$ for all $\gamma, \gamma' \in \mathcal{D}(pCCPS)$ follows directly by the fact that if we take two functions $\omega, \omega' : pCCPS \times pCCPS \to [0,1]$ such that $\omega(M,N) = \omega'(N,M)$ for all $M, N \in pCCPS$, then $\omega \in \Omega(\gamma, \gamma')$ if and only if $\omega' \in \Omega(\gamma, \gamma')$.

To prove the triangle inequality $K(d)(\gamma_1, \gamma_2) \leq K(d)(\gamma_1, \gamma_3) + K(d)(\gamma_3, \gamma_2)$ for all $\gamma_1, \gamma_2, \gamma_3 \in \mathcal{D}(pCCPS)$, we consider the function $\omega : pCCPS \times pCCPS \to [0,1]$ defined for all $M_1, M_2 \in pCCPS$ as $\omega(M_1, M_2) = \sum_{M_3 \in pCCPS} \gamma_1(M_3) \cdot \gamma_3(M_3) \cdot d(M_1, M_3)$, where the function $\omega_1 \in \Omega(\gamma_1, \gamma_3)$ is one of the optimal matchings realising $K(d)(\gamma_1, \gamma_3)$ and $\omega_2 \in \Omega(\gamma_3, \gamma_2)$ one of the optimal matchings realising $K(d)(\gamma_3, \gamma_2)$. Then, we prove that (i) $\omega$ is a matching in $\Omega(\gamma_1, \gamma_2)$, and (ii) $\sum_{M_1, M_2 \in pCCPS} \omega(M_1, M_2) \cdot d(M_1, M_2) \leq K(d)(\gamma_1, \gamma_2) + K(d)(\gamma_3, \gamma_2)$, which immediately implies $K(d)(\gamma_1, \gamma_2) \leq K(d)(\gamma_1, \gamma_3) + K(d)(\gamma_3, \gamma_2)$. To show (ii) we observe that the proof that the left marginal of $\omega$ is $\gamma_1$ by

$$\sum_{M_2 \in pCCPS} \omega(M_1, M_2) = \sum_{M_2 \in pCCPS} \sum_{M_3 \in pCCPS} \gamma_1(M_3) \cdot \omega(M_1, M_2) = \sum_{M_3 \in pCCPS} \gamma_1(M_3) \cdot \omega(M_1, M_3) (by \omega_1 \in \Omega(\gamma_1, \gamma_3))$$

and we observe that the proof that the right marginal of $\omega$ is $\gamma_2$ is analogous. Then, we show (ii) by

$$\sum_{M_1, M_2 \in pCCPS} \omega(M_1, M_2) \cdot d(M_1, M_2) = \sum_{M_1, M_2 \in pCCPS} \sum_{M_3 \in pCCPS} \gamma_1(M_3) \cdot \omega(M_1, M_2) \cdot d(M_1, M_2) = \sum_{M_1, M_2 \in pCCPS} \sum_{M_3 \in pCCPS} \gamma_1(M_3) \cdot \omega(M_1, M_3) \cdot d(M_1, M_3) \leq \sum_{M_1, M_2 \in pCCPS} \gamma_1(M_3) \cdot \omega(M_1, M_3) \cdot d(M_1, M_3) + \sum_{M_1, M_2 \in pCCPS} \sum_{M_3 \in pCCPS} \gamma_3(M_3) \cdot \omega(M_2, M_3) \cdot d(M_3, M_2) = \sum_{M_1, M_2 \in pCCPS} \omega(M_1, M_3) \cdot d(M_1, M_3) + \sum_{M_2 \in pCCPS} \omega(M_2, M_3) \cdot d(M_3, M_2) = K(d)(\gamma_1, \gamma_3) + K(d)(\gamma_3, \gamma_2)$$

where the inequality follows from the triangular property of $d$ and the third last equality follows by $\omega_1 \in \Omega(\gamma_1, \gamma_3)$ and $\omega_2 \in \Omega(\gamma_3, \gamma_2)$. \hfill $\square$

Now we show that, given any weak bisimulation metric $d$ with $d(M,N) < 1$, then $N$ can mimic weak transitions $M \overset{\alpha}{\Rightarrow} \gamma_M$ besides those of the form $M \overset{\alpha}{\Rightarrow} \gamma_M$.

Lemma 3. Assume a weak bisimulation metric $d$ and $M, N \in pCCPS$ with $d(M,N) < 1$. If $M \overset{\alpha}{\Rightarrow} \gamma_M$, then there is a transition $N \overset{\alpha}{\Rightarrow} \gamma_N$ such that $K(d)(\gamma_M, (1 - |\gamma_M|)\text{Dead}) + (1 - |\gamma_N|)\text{Dead}) \leq d(M,N)$.\hfill $\square$

Proof. We proceed by induction on the length $n$ of $M \overset{\alpha}{\Rightarrow} \gamma_M$.

Base case $n = 1$. We have two sub-cases: The first is $\alpha = \tau$ and $\gamma_M = \overline{M}$, the second is $M \overset{\alpha}{\Rightarrow} \gamma_M$. In the first case, by definition of $\overset{\tau}{\Rightarrow}$ we have $N \overset{\tau}{\Rightarrow} \overline{N}$ and the thesis holds for $\gamma_N = \overline{N}$ by observing that
\[ K(d)(M + (1 - |M|)\text{Dead}), N + (1 - |N|)\text{Dead} = K(d)(M, N) = d(M, N). \]

In the second case, the thesis follows directly by the definition of weak simulation metric.

Inductive step \( n > 1 \). The derivation \( M \xrightarrow{\alpha} \gamma_M \) is obtained by \( M \xrightarrow{\beta_1} \rho_M \) and \( \rho_M \xrightarrow{\beta_2} \gamma_M \), for some distribution \( \rho_M \in \mathcal{D}(\text{pCCPS}) \). The length of the derivation \( M \xrightarrow{\beta_1} \rho_M \) is \( n - 1 \) and hence, by the inductive hypothesis, there is a transition \( N \xrightarrow{\beta_1} \rho_N \) such that \( K(d)(\rho_M + (1 - |\rho_M|)\text{Dead}, \rho_N + (1 - |\rho_N|)\text{Dead}) \leq d(M, N) \). The sub-distributions \( \rho_M \) and \( \rho_N \) are of the form \( \rho_M = \sum_{i \in I} \rho_i \cdot M_i \) and \( \rho_N = \sum_{j \in J} q_j \cdot N_j \). We have two sub-cases: The first is \( \beta_1 = \tau \) and \( \beta_2 = \alpha \), the other is \( \beta_1 = \alpha \) and \( \beta_2 = \tau \).

We consider the case \( \beta_1 = \tau \) and \( \beta_2 = \alpha \), the other is analogous. In this case we have \( |\rho_M| = |\rho_N| = 1 \) and \( K(d)(\rho_M, \rho_N) \leq d(M, N) \). The transition \( \rho_M \xrightarrow{\beta_1} \gamma_M \) is derived from a \( \beta_2 \)-transition by some of the CPSs \( M_i \), namely \( I \) is partitioned into sets \( I_1 \cup I_2 \) such that for all \( i \in I_1 \) we have \( M_i \xrightarrow{\beta_2} \gamma_i \) for suitable distributions \( \gamma_i \), for each \( i \in I_2 \) we have \( M_i \xrightarrow{\beta_2} \gamma_i \). Analogously, \( J \) is partitioned into sets \( J_1 \cup J_2 \) such that for all \( j \in J_1 \) we have \( N_j \xrightarrow{\beta_2} \gamma_j \) for suitable distributions \( \gamma_j \) and for each \( j \in J_2 \) we have \( N_j \xrightarrow{\beta_2} \gamma_j \). This gives \( \rho_N \xrightarrow{\beta_2} \gamma_N \) with \( \gamma_N = \sum_{j \in J} q_j \cdot \gamma_j \). Since we had \( N \xrightarrow{\beta_1} \rho_N \), we can conclude \( N \xrightarrow{\alpha} \gamma_N \). In the following we prove that the transitions \( N_j \xrightarrow{\beta_2} \gamma_j \) can be chosen so that \( K(d)(\gamma_M + (1 - |\gamma_M|)\text{Dead}, \gamma_N + (1 - |\gamma_N|)\text{Dead}) \leq d(M, N) \), which concludes the proof.

Let \( \omega \) be one of the optimal matchings realising \( K(d)(\rho_M, \rho_N) \). We can rewrite the distributions \( \rho_M = \sum_{i \in I, j \in J} \omega(M_i, N_j) \cdot M_i \) and \( \rho_N = \sum_{i \in I, j \in J} \omega(M_i, N_j) \cdot N_j \). For all \( i \in I_1 \) and \( j \in J \), define \( \gamma_{i,j} = \gamma_i \). We can rewrite \( \gamma_M \) as \( \gamma_M = \sum_{i \in I, j \in J} \omega(M_i, N_j) \cdot \gamma_{i,j} \). Analogously, for each \( j \in J_i \) and \( i \in I \) we note that the transition \( q_j \cdot N_j \xrightarrow{\beta_2} \gamma_j \) can always be split into \( \sum_{i \in I} \omega(M_i, N_j) \cdot N_j \xrightarrow{\beta_2} \sum_{i \in I} \omega(M_i, N_j) \cdot \gamma_{i,j} \) so that we can rewrite \( \gamma_j \) as \( \gamma_j = \sum_{i \in I} \omega(M_i, N_j) \cdot \gamma_{i,j} \) and \( \gamma_N = \sum_{i \in I, j \in J} \omega(M_i, N_j) \cdot \gamma_{i,j} \). Then we note that for all \( i \in I_1 \) and \( j \in J_1 \) with \( d(M_i, N_j) < 1 \), the transition \( N_j \xrightarrow{\beta_2} \gamma_j \) can be chosen so that \( K(d)(\gamma_{i,j}, \gamma_{i,j} + (1 - |\gamma_{i,j}|)\text{Dead}) \leq d(M_i, N_j) \).

For all \( i \in I_1 \) and \( j \in J_1 \) with \( d(M_i, N_j) < 1 \), let \( \omega_{i,j} \) be one of the optimal matchings realising \( K(d)(\gamma_{i,j}, \gamma_{i,j} + (1 - |\gamma_{i,j}|)\text{Dead}) \). Define \( \omega' : \text{pCCPS} \times \text{pCCPS} \rightarrow [0, 1] \) as the function such that

\[
\omega'(M', N') = \begin{cases} 
\sum_{i \in I_1, j \in J_1} \omega(M_i, N_j) \cdot \omega_{i,j}(M', N') & \text{if } M' \neq \text{Dead} \neq N' \\
\sum_{i \in I_1, j \in J_1} \omega(M_i, N_j) \cdot \omega_{i,j}(M', N') + \sum_{i \in I_2, j \in J_2} \omega(M_i, N_j) \cdot \gamma_{i,j}(M') & \text{if } M' = \text{Dead} \neq N' \\
\sum_{i \in I_1, j \in J_1} \omega(M_i, N_j) \cdot \omega_{i,j}(M', N') + \sum_{i \in I_2, j \in J_2} \omega(M_i, N_j) \cdot \gamma_{i,j}(M') & \text{if } M' \neq \text{Dead} = N' \\
\sum_{i \in I_1, j \in J_1} \omega(M_i, N_j) \cdot \omega_{i,j}(M', N') + \sum_{i \in I_1, j \in J_2} \omega(M_i, N_j) \cdot \gamma_{i,j}(M') & \text{if } M' = \text{Dead} = N'. 
\end{cases}
\]

To infer the proof obligation \( K(d)(\gamma_M + (1 - |\gamma_M|)\text{Dead}, \gamma_N + (1 - |\gamma_N|)\text{Dead}) \leq d(M, N) \) we show that (i) \( \omega' \) is a matching in \( \Omega(\gamma_M + (1 - |\gamma_M|)\text{Dead}, \gamma_N + (1 - |\gamma_N|)\text{Dead}) \), and (ii) \( \sum_{M', N' \in \text{pCCPS}} \omega'(M', N') \cdot d(M', N') \leq d(M, N) \).

To show (i) we prove that the left marginal of \( \omega' \) is \( \gamma_M + (1 - |\gamma_M|)\text{Dead} \). The proof that the right
marginal is \( \gamma_N + (1 - |\gamma_N|) \text{Dead} \) is analogous. For any CPS \( M' \neq \text{Dead} \), we have

\[
\sum_{N' \in \text{pCPS}} \omega'(M', N') = \sum_{N' \neq \text{Dead}} \sum_{i \in I_1, j \in J_1} \omega(M_i, N_j) \cdot \omega_i, j(M', N') + \sum_{i \in I_1, j \in J_2} \omega(M_i, N_j) \cdot \omega_i, j(M', \text{Dead}) \\
+ \sum_{i \in I_2, j \in J_2} \omega(M_i, N_j) \cdot \gamma_i, j(M') \\
= \sum_{i \in I_1, j \in J_1} \omega(M_i, N_j) \cdot \sum_{N' \in \text{pCPS}} \omega_{i, j}(M', N') + \sum_{i \in I_1, j \in J_2} \omega(M_i, N_j) \cdot \gamma_{i, j}(M') \\
= \sum_{i \in I_1, j \in J_1} \omega(M_i, N_j) \cdot \gamma_i, j(M') + \sum_{i \in I_1, j \in J_2} \omega(M_i, N_j) \cdot \gamma_{i, j}(M') \\
= (\gamma_M + (1 - |\gamma_M|) \text{Dead})(M')
\]

with the third equality by the fact that \( \omega_{i, j} \) is a matching in \( \Omega(\gamma_i, j, \gamma_{i, j}) \).

Consider now the CPS \( \text{Dead} \). In this case we have that

\[
\sum_{N' \in \text{pCPS}} \omega'(\text{Dead}, N') = \sum_{N' \neq \text{Dead}} \sum_{i \in I_1, j \in J_1} \omega(M_i, N_j) \cdot \omega_i, j(\text{Dead}, N') + \sum_{N' \neq \text{Dead}} \sum_{i \in I_2, j \in J_2} \omega(M_i, N_j) \cdot \gamma_{i, j}(N') \\
+ \sum_{i \in I_1, j \in J_1} \omega(M_i, N_j) \cdot \gamma_i, j(\text{Dead}) + \sum_{i \in I_2, j \in J_2} \omega(M_i, N_j) \\
= \sum_{i \in I_1, j \in J_1} \omega(M_i, N_j) \cdot \gamma_i, j(\text{Dead}) + \sum_{i \in I_1, j \in J_2} \omega(M_i, N_j) \\
+ \sum_{i \in I_1, j \in J_2} \omega(M_i, N_j) \cdot \gamma_{i, j}(\text{Dead}) + \sum_{i \in I_2, j \in J_2} \omega(M_i, N_j) \\
= (\gamma_M + (1 - |\gamma_M|) \text{Dead})(\text{Dead})
\]

where the third equality follows by observing that, being \( \omega_{i, j} \) a matching in \( \Omega(\gamma_i, j, \gamma_{i, j}) \), then we have

\[
\sum_{N' \in \text{pCPS}} \sum_{i \in I_1, j \in J_1} \omega(M_i, N_j) \cdot \omega_i, j(\text{Dead}, N') = \sum_{i \in I_1, j \in J_1} \omega(M_i, N_j) \cdot \gamma_i, j(\text{Dead}),
\]

and being \( \gamma_{i, j} \) a distribution, then

\[
\sum_{N' \in \text{pCPS}} \sum_{i \in I_1, j \in J_1} \omega(M_i, N_j) \cdot \gamma_{i, j}(N') = \sum_{i \in I_1, j \in J_1} \omega(M_i, N_j),
\]

and the last equality follows by

\[
\sum_{i \in I_1, j \in J_1} \omega(M_i, N_j) \cdot \gamma_{i, j}(\text{Dead}) = \sum_{i \in I_1, j \in J_1} \sum_{i \in I_1, j \in J_1} \omega(M_i, N_j).
\]

To prove \( \text{[3]} \) by looking at the definition of \( \omega' \) above we get that \( \sum_{M', N' \in \text{pCPS}} \omega'(M', N') \cdot d(M', N') \) is the summation of the following values:

- \( \sum_{M' \neq \text{Dead}, N' \neq \text{Dead}} \sum_{i \in I_1, j \in J_1} \omega(M_i, N_j) \cdot \omega_i, j(M', N') \cdot d(M', N') \)
- \( \sum_{M' \neq \text{Dead}} \sum_{i \in I_1, j \in J_1} \omega(M_i, N_j) \cdot \omega_i, j(M', \text{Dead}) \cdot d(M', \text{Dead}) + \sum_{i \in I_1, j \in J_2} \omega(M_i, N_j) \cdot \gamma_i, j(M') \cdot d(M', \text{Dead}) \)
- \( \sum_{N' \neq \text{Dead}} \sum_{i \in I_1, j \in J_1} \omega(M_i, N_j) \cdot \omega_i, j(\text{Dead}, N') \cdot d(\text{Dead}, N') + \sum_{i \in I_1, j \in J_2} \omega(M_i, N_j) \cdot \gamma_i, j(N') \cdot d(\text{Dead}, N') \)
- \( \sum_{i \in I_1, j \in J_1} \omega(M_i, N_j) \cdot \omega_i, j(\text{Dead}, \text{Dead}) \cdot d(\text{Dead}, \text{Dead}) + \sum_{i \in I_1, j \in J_2} \omega(M_i, N_j) \cdot \gamma_i, j(\text{Dead}) \cdot d(\text{Dead}, \text{Dead}) \\
+ \sum_{i \in I_2, j \in J_2} \omega(M_i, N_j) \cdot \gamma_i, j(\text{Dead}) \cdot d(\text{Dead}, \text{Dead}) + \sum_{i \in I_2, j \in J_2} \omega(M_i, N_j) \cdot d(\text{Dead}, \text{Dead}) \)

By moving the first summand of the second, third and fourth items to the first item, we rewrite this summation as the summation of the following values:

- \( \sum_{M', N' \in \text{pCPS}} \sum_{i \in I_1, j \in J_1} \omega(M_i, N_j) \cdot \omega_i, j(M', N') \cdot d(M', N') \)
- \( \sum_{i \in I_1, j \in J_2} \omega(M_i, N_j) \cdot \gamma_i, j(M') \cdot d(M', \text{Dead}) \)
- \( \sum_{i \in I_2, j \in J_1} \omega(M_i, N_j) \cdot \gamma_i, j(N') \cdot d(\text{Dead}, N') \)
- \( \sum_{i \in I_1, j \in J_1} \omega(M_i, N_j) \cdot \gamma_i, j(\text{Dead}) \cdot d(\text{Dead}, \text{Dead}) + \sum_{i \in I_1, j \in J_1} \omega(M_i, N_j) \cdot \gamma_i, j(N') \cdot d(\text{Dead}, \text{Dead}) + \sum_{i \in I_1, j \in J_1} \omega(M_i, N_j) \cdot d(\text{Dead}, \text{Dead}) \)

By the definition of \(\omega_{ij}\) the first item is \(\sum_{i \in I, j \in J} \omega(M_i, N_j) \cdot K(d)(\gamma_i, \gamma_j')\). If \(d(M_i, N_j) < 1\), we choose \(\gamma_j'\) such that \(K(d)(\gamma_i, \gamma_j') \leq d(M_i, N_j)\). If \(d(M_i, N_j) = 1\), then \(K(d)(\gamma_i, \gamma_j') \leq d(M_i, N_j)\) is immediate. Henceforth we are sure that in all cases the first item is less or equal \(\sum_{i \in I, j \in J} \omega(M_i, N_j) \cdot d(M_i, N_j)\). The second item is clearly less or equal than \(\sum_{i \in I, j \in J} \omega(M_i, N_j)\). Finally, the last item is 0 since \(d(\text{Dead}, \text{Dead}) = 0\). Summarising, we have \(\sum_{i' \in I', j' \in J'} \omega(M', N') \cdot d(M', N') \leq \sum_{i \in I, j \in J} \omega(M_i, N_j) \cdot d(M_i, N_j) + \sum_{i \in I, j \in J} \omega(M_i, N_j) + \sum_{i' \in I', j' \in J'} \omega(M_i, N_j)\). Since \(K(d)(\rho_M, \rho_N)\) is the summation of the following values:

- \(\sum_{i \in I, j \in J} \omega(M_i, N_j) \cdot d(M_i, N_j)\)
- \(\sum_{i \in I, j \in J} \omega(M_i, N_j) \cdot d(M_i, N_j) = \sum_{i \in I, j \in J} \omega(M_i, N_j) (M_i \xrightarrow{\beta_i} \text{ and } N_j \xrightarrow{\beta_j} \text{ give } d(M_i, N_j) = 1)\)
- \(\sum_{i \in I, j \in J} \omega(M_i, N_j) \cdot d(M_i, N_j) = \sum_{i \in I, j \in J} \omega(M_i, N_j) (N_j \xrightarrow{\beta_i} \text{ and } M_i \xrightarrow{\beta_j} \text{ give } d(M_i, N_j) = 1)\)
- \(\sum_{i \in I, j \in J} \omega(M_i, N_j) \cdot d(M_i, N_j)\).

it follows \(\sum_{i \in I, j \in J} \omega(M_i, N_j) \cdot d(M_i, N_j) + \sum_{i \in I, j \in J} \omega(M_i, N_j) + \sum_{i \in I, j \in J} \omega(M_i, N_j) \leq K(d)(\rho_M, \rho_N)\). Since we had \(K(d)(\rho_M, \rho_N) \leq d(M, N)\) we can conclude \(\sum_{i' \in I', j' \in J'} \omega(M', N') \cdot d(M', N') \leq d(M, N)\), as required.

We are now ready to prove that all \(d^n\) are pseudometrics.

**Proof of Proposition 7** We have to prove that \(d^n(M, M) = 0\), \(d^n(M, N) = d^n(N, M)\) and \(d^n(M, N) \leq d^n(M, O) + d^n(O, N)\) for all \(M, N, O \in \text{pCCPS}\). We reason by induction over \(n\). The base case \(n = 0\) is immediate since \(d^0(M, N) = 0\) for all \(M, N \in \text{pCCPS}\). We consider the inductive step \(n + 1\).

Let us start with proving \(d^{n+1}(M, M) = 0\). We have to show that for each transition \(M \xrightarrow{\alpha} \gamma\) there is a transition \(M \xrightarrow{\alpha} \rho\) with \(K(d^n)(\gamma, \rho + (1 - |\rho|)\text{Dead}) = 0\). We choose \(\rho = \gamma\) and the transition \(M \xrightarrow{\alpha} \gamma\). We obtain \(K(d^n)(\gamma, \rho + (1 - |\rho|)\text{Dead}) = K(d^n)(\gamma, \gamma) = 0\), with the last equality by the inductive hypothesis and **Proposition 12**.

The symmetry \(d^{n+1}(N, M) = d^{n+1}(N, M)\) follows by \(d^{n+1}(M, N) = B(d^n)(M, N) = B(d^n)(N, M) = d^{n+1}(N, M)\), where the second equality follows immediately by the definition of \(B\).

Finally we prove the triangular property \(d^{n+1}(M, N) \leq d^{n+1}(M, O) + d^{n+1}(O, N)\). This result is immediate if \(d^{n+1}(M, O) = 1\) or \(d^{n+1}(O, N) = 1\). Otherwise, it is enough to prove that any \(M \xrightarrow{\alpha} \gamma\) is mimicked by some transition \(N \xrightarrow{\alpha} \gamma\) with \(K(d^n)(\gamma, \gamma + (1 - |\gamma|)\text{Dead}) \leq d^{n+1}(M, O) + d^{n+1}(O, N)\). From \(M \xrightarrow{\alpha} \gamma\) and \(d^{n+1}(M, O) < 1\) we immediately infer that there is a transition \(O \xrightarrow{\alpha} \gamma\) with \(K(d^n)(\gamma, \gamma + (1 - |\gamma|)\text{Dead}) \leq d^{n+1}(M, O)\). By **Lemma 3** from \(O \xrightarrow{\alpha} \gamma\) and \(d^{n+1}(O, N) < 1\) there is a transition \(N \xrightarrow{\alpha} \gamma\) such that \(K(d^n)(\gamma, \gamma + (1 - |\gamma|)\text{Dead}) \leq d^{n+1}(O, N)\). By the inductive hypothesis and **Proposition 12** we get that \(K(d^n)\) is a pseudometric, hence it satisfies the triangle inequality, namely \(K(d^n)(\gamma, \gamma + (1 - |\gamma|)\text{Dead}) \leq K(d^n)(\gamma, \gamma + (1 - |\gamma|)\text{Dead}) + K(d^n)(\gamma + (1 - |\gamma|)\text{Dead}, \gamma + (1 - |\gamma|)\text{Dead})\). Therefore we can conclude the proof by \(K(d^n)(\gamma, \gamma + (1 - |\gamma|)\text{Dead}) \leq K(d^n)(\gamma, \gamma + (1 - |\gamma|)\text{Dead}) + K(d^n)(\gamma + (1 - |\gamma|)\text{Dead}, \gamma + (1 - |\gamma|)\text{Dead}) \leq d^{n+1}(M, O) + d^{n+1}(O, N)\).

In order to prove the compositionality or our weak bisimilarity metrics, i.e. **Theorem 3** we divide its statement in six different propositions. To prove that \(\approx_p\) preserves the compositionality we need a number of technical lemmas.
Given a distribution \( \gamma \) over CPSs and a CPS \( O \), we denote with \( \gamma \uplus O \) the distribution defined by \( (\gamma \uplus O)(M \uplus O) = \gamma(M) \) for all CPSs \( M \).

**Lemma 4** serves to propagate untimed actions on parallel CPSs.

**Lemma 4.** Assume two physically disjoint CPSs \( M_1 \) and \( M_2 \) such that \( M_2 = E_2; S_2 \uplus P_2 \) and \( E_2 = (\text{evol}^2, \text{meas}^2, \text{inv}^2) \). If \( M_1 \xrightarrow{\tau} \gamma \), with \( \alpha \neq \text{tick} \), and \( S_2 \in \text{inv}^2 \) then \( M_1 \uplus M_2 \xrightarrow{\alpha} \gamma \uplus M_2 \).

**Proof.** If \( M_1 \) is the CPS Dead then also \( M_1 \uplus M_2 \) is Dead and the thesis is immediate. Consider the case \( M_1 \neq \text{Dead} \). Let us assume that \( M_1 = E_1; S_1 \uplus P_1 \) with \( E_1 = (\text{evol}^1, \text{meas}^1, \text{inv}^1) \) and \( S_1 = (\xi^1_1, \xi^1_2, \xi^1_3) \). Moreover, assume that \( S_2 = (\xi^2_1, \xi^2_2, \xi^2_3) \). We consider the case in which \( M_1 \xrightarrow{\alpha} \gamma \) is derived by rule (SensRead). The other cases where the transition is derived by the other rules in Table 2 can be proved in a similar manner. In this case, we have \( \alpha = \tau \) and there are a sensor \( s \), probability values \( p_i \) and real values \( v_i \) with \( i \in I \) and a distribution \( \pi \) such that the rule (SensRead) instances as

\[
P_1 \xrightarrow{s^2(I)} \pi \quad (\xi^1_1(s) = \sum_{i \in I} p_i \cdot v_i, \xi^1_1 \in \text{inv}^1)
\]

and \( \gamma = E_1; (\xi^1_1, \xi^1_2, \xi^1_3) \bowtie \sum_{i \in I} p_i \cdot \pi^i \{v\} \).

Now we argue that we can apply rule (SensRead) to infer a transition by \( M_1 \uplus M_2 \). Recall that \( M_1 \uplus M_2 \) is the CPS \( (E_1 \uplus E_2); (\xi^1_1 \bowtie \xi^2_1, \xi^1_2 \bowtie \xi^2_2, \xi^1_3 \bowtie \xi^2_3) \bowtie P_1 \parallel P_2 \). Let \( E_1 \uplus E_2 = (\text{evol}^1, \text{meas}^1, \text{inv}^1) \). From \( P_1 \xrightarrow{s^2(I)} \pi \), by rule (Par) in Table 1 we can derive the transition \( P_1 \parallel P_2 \xrightarrow{s^2(I)} \pi \parallel \overline{P_2} \), which is one of the premises of rule (SensRead) necessary to infer a transition by \( (\xi^1_1 \bowtie \xi^2_1, \xi^1_2 \bowtie \xi^2_2, \xi^1_3 \bowtie \xi^2_3) \bowtie P_1 \parallel P_2 \). Then, the premise \( \xi^1_1 \bowtie \xi^2_1 \in \text{inv}^1 \) (SensRead) follows by \( \xi^1_1 \in \text{inv}^1 \), the hypothesis \( \xi^2_1 \in \text{inv}^2 \) and the property \( \xi^1_1 \bowtie \xi^2_1 \in \text{inv} \) iff \( \xi^1_1 \in \text{inv}^1 \) and \( \xi^2_1 \in \text{inv}^2 \). Finally, the premise \( (\xi^1_1 \bowtie \xi^2_1)(s) = \sum_{i \in I} p_i \cdot v_i \) follows by \( (\xi^1_1 \bowtie \xi^2_1)(s) = \xi^1_1(s) \) and \( \xi^1_1(s) = \sum_{i \in I} p_i \cdot v_i \). Therefore we have

\[
P_1 \parallel P_2 \xrightarrow{s^2(I)} \pi \parallel \overline{P_2} \quad (\xi^1_1 \bowtie \xi^2_1)(s) = \sum_{i \in I} p_i \cdot v_i \quad \xi^1_1 \bowtie \xi^2_1 \in \text{inv}
\]

with \( (E_1 \uplus E_2); (\xi^1_1 \bowtie \xi^2_1, \xi^1_2 \bowtie \xi^2_2, \xi^1_3 \bowtie \xi^2_3) \bowtie \sum_{i \in I} p_i \cdot (\pi \parallel \overline{P_2})^i \{v\} = \gamma \uplus M_2 \).

**Lemma 4** can be generalised to weak transitions.

**Lemma 5.** Assume two physically disjoint CPSs \( M_1 \) and \( M_2 \) such that \( M_2 = E_2; S_2 \uplus P_2 \) and \( E_2 = (\text{evol}^2, \text{meas}^2, \text{inv}^2) \). If \( M_1 \xrightarrow{\tau} \gamma \), with \( \alpha \neq \text{tick} \), and \( S_2 \in \text{inv}^2 \) then \( M_1 \uplus M_2 \xrightarrow{\tau} \gamma\uplus M_2 \).

**Proof.** By induction over the length \( n \) of \( \overrightarrow{\alpha} \). The base case \( n = 1 \) is given by **Lemma 4**. Consider the inductive step \( n + 1 \). We have \( M_1 \xrightarrow{\alpha_1} \gamma' \xrightarrow{\alpha_2} \gamma \) with either \( \alpha_1 = \alpha \) and \( \alpha_2 = \tau \), or \( \alpha_1 = \tau \) and \( \alpha_2 = \alpha \). Since the length of \( \overrightarrow{\alpha} \) is \( n \), we can apply the inductive hypothesis and infer \( M_1 \uplus M_2 \xrightarrow{\alpha_1} \gamma' \uplus M_2 \). Assume \( \gamma' = \sum_{j \in J} p_j \cdot M_j \), for suitable probability values \( p_j \) and CPS \( M_j \). By definition, \( \gamma \xrightarrow{\alpha_2} \gamma \) implies that there exists a subset \( J \subseteq I \) with \( M_j \xrightarrow{\alpha_2} \gamma_j \) for all \( j \in J \). For \( i \in I \setminus J \) and \( \gamma = \sum_{j \in J} p_j \cdot M_j \). We can prove now that for any \( j \in J \) we have \( M_j \uplus M_2 \xrightarrow{\alpha_2} \gamma_j \uplus M_2 \). We distinguish two cases. The first case is \( M_j \xrightarrow{\alpha_2} \gamma_j \). By **Lemma 4** we get \( M_j \uplus M_2 \xrightarrow{\alpha_2} \gamma_j \uplus M_2 \), and, therefore, \( M_j \uplus M_2 \xrightarrow{\alpha_2} \gamma_j \uplus M_2 \). The second case is \( \alpha_2 = \tau \) and \( \gamma_j = \overline{M_j} \). We immediately have \( M_j \uplus M_2 \xrightarrow{\tau} \gamma_j \uplus M_2 \). Hence \( \sum_{j \in J} M_j \uplus M_2 \xrightarrow{\alpha_2} \sum_{j \in J} \gamma_j \uplus M_2 \), namely
\[ \gamma' \cup M_2 \xrightarrow{\bar{\alpha}} \gamma \cup M_2. \] Then, from \( M \cup M_2 \xrightarrow{\bar{\alpha}} \gamma' \cup M_2 \) and \( \gamma' \cup M_2 \xrightarrow{\bar{\alpha}} \gamma \cup M_2 \) we get \( M \cup M_2 \xrightarrow{\bar{\alpha}} \gamma \cup M_2 \), which completes the proof. \( \square \)

Next lemma says that the invariants of CPSs in distance \(< 1\) must agree.

**Lemma 6.** Assume two CPSs \( M_1 \) and \( M_2 \) such that \( M_i = E_i; S_i \parallel P_i \) and \( E_i = \langle \text{evol}_i, \text{meas}_i, \text{inv}_i \rangle \), for \( i = 1, 2 \). \( \) If \( d(M_1, M_2) < 1 \) then \( S_1 \in \text{inv} \) iff \( S_2 \in \text{inv} \).

**Proof.** The proof is by contradiction. Assume that \( d(M_1, M_2) < 1 \), \( S_1 \in \text{inv} \) and \( S_2 \notin \text{inv} \). We show that \( M_1 \xrightarrow{\text{tick}} \) and \( M_2 \xrightarrow{\text{tick}} \), which contradicts \( d(M_1, M_2) < 1 \). By the well timedness property for CPSs (Theorem 1 last item), there exists a natural \( n \) such that all derivations \( M_1 \xrightarrow{\tau} N_1 \xrightarrow{\tau} \cdots \xrightarrow{\tau} N_k \) are such that \( k \leq n \), then we have \( N_k \xrightarrow{\tau} \). Since \( N_k \xrightarrow{\tau} \), by the maximal progress property for CPSs (Theorem 1 second item) it follows that \( N_k \xrightarrow{\text{tick}} \gamma \), for some \( \gamma \). We conclude \( M_1 \xrightarrow{\text{tick}} \). Since \( S_2 \notin \text{inv} \), the CPS \( M_2 \) can perform only the step \( M_2 \xrightarrow{\tau} \text{Dead} \) and \( \text{Dead} \) can not perform any action, and hence, \( M_2 \xrightarrow{\text{tick}} \). \( \square \)

Here comes one of the main technical result: the bisimilarity metric is preserved by the parallel composition of physically disjoint CPSs.

**Proposition 13.** \( d(M \cup O, N \cup O) \leq d(M, N) \), for any physically disjoint CPS \( O \).

**Proof.** The case \( d(M, N) = 1 \) is immediate, therefore we assume \( d(M, N) < 1 \). Let us define the function \( d : \text{pCCPS} \times \text{pCCPS} \rightarrow [0, 1] \) by \( d(M \cup O, N \cup O) = d(M, N) \) for all \( M, N, O \in \text{pCCPS} \). To prove the thesis it is enough to show that \( d \) is a weak bisimulation metric. In fact, since \( d \) is the minimal weak bisimulation metric, we infer \( d \subseteq d \), thus giving \( d(M \cup O, N \cup O) \leq d(M \cup O, N \cup O) = d(M, N) \). To prove that \( d \) is a weak bisimulation metric, we show that any transition \( M \cup O \xrightarrow{a} \gamma \) is simulated by some transition \( N \cup O \xrightarrow{\bar{a}} \gamma' \) with \( K(d)(\gamma; \gamma') + (1 - |\gamma'|)|\text{Dead}| \leq d(M \cup O, N \cup O) \). The cases where one of the CPSs \( M \), \( N \) and \( O \) are Dead is immediate. Hence, assume that \( M \), \( N \) and \( O \) are not Dead. Let us assume that \( M_1 = E_1; S_1 \parallel P_1 \) with \( E_1 = \langle \text{evol}_1, \text{meas}_1, \text{inv}_1 \rangle \) and \( S_1 = \langle \xi_1^1, \xi_2^1, \xi_3^1 \rangle \). Moreover, assume that \( O = E_2; S_2 \parallel P_2 \) with \( E_2 = \langle \text{evol}_2, \text{meas}_2, \text{inv}_2 \rangle \) and \( S_2 = \langle \xi_2^1, \xi_2^2, \xi_3^2 \rangle \). Finally \( E_1 \cup E_2 = \langle \text{evol}, \text{meas}, \text{inv} \rangle \).

We proceed by case analysis on how \( M \cup O \xrightarrow{a} \gamma \) is derived. The cases are the following:

- **The transition** \( M \cup O \xrightarrow{\tau} \gamma \) **is derived by rule (SensRead) in Table 2** instantiated as
  \[
  P_1 \parallel P_2 \xrightarrow{\text{Sens}(\bar{\alpha})} \pi \quad (\xi^0 \cup \xi^2) (s) = \sum_{i \in I} P_i \cdot \pi \quad \xi^0 \cup \xi^2 \in \text{inv}
  \]
  with \( \gamma = (E_1 \cup E_2); S_1 \cup S_2 \parallel \sum_{i \in I} P_i \cdot \pi \{\xi^2\} \).

- **The transition** \( M \cup O \xrightarrow{a} \gamma \) **is derived by rule (ActWrite) in Table 2** instantiated as
  \[
  \langle \xi^1 \cup \xi^2, \xi^1 \cup \xi^2, \xi^1 \cup \xi^2, \xi^1 \cup \xi^2 \rangle \xrightarrow{\text{ActWrite}(\bar{\alpha})} \pi \quad \xi^1 \cup \xi^2 \in \text{inv}
  \]
  with \( \gamma = (E_1 \cup E_2); S_1 \cup S_2 \parallel \xi^1 \cup \xi^2 \) and \( \xi^1 \cup \xi^2 \parallel \pi \).

- **The transition** \( M \cup O \xrightarrow{\tau} \gamma \) **is derived by rule (SensWrite) in Table 2** instantiated as
  \[
  P_1 \parallel P_2 \xrightarrow{\tau} \pi \quad (S_1 \cup S_2) \in \text{inv}
  \]
  with \( \gamma = (E_1 \cup E_2); S_1 \cup S_2 \parallel \pi \).
We show only the first case, the other are analogous. We recall that, by definition of operator $\cup$, the physical environments $E_1$ and $E_2$ have different physical devices. Thus, there are two cases:

- $s$ is a sensor of $E_1$. In this case, the transition $P_1 \parallel P_2 \xrightarrow{s(\cdot)} \pi'$, where $\pi'$ is a process distribution such that $\pi = \pi' \parallel P_2$.

First we argue that rule (SensRead) can be used to derive a transition by $M$. From $(S_1 \cup S_2) \in \text{inv}$, by definition of $E_1 \cup E_2$, we get both $S_1 \in \text{inv} \parallel$ and $S_2 \in \text{inv} \parallel$. Since $s$ is a sensor of $\xi_1$, we derive $\xi_1(s) = \sum_{i \in I} P_i \cdot \nu_i$. Summarising, we have $P_1 \xrightarrow{s(\cdot)} \pi'$, $S_1 \in \text{inv} \parallel$, and $\xi_1(s) = \sum_{i \in I} P_i \cdot \nu_i$, which allows us to apply rule (SensRead) and derive $S_1 \cup P_1 \xrightarrow{\tau} S_1 \cup \sum_{i \in I} P_i \cdot \nu_i \{i/\xi \}$, namely $M \xrightarrow{\tau} \pi' = E_1; S_1 \cup \sum_{i \in I} P_i \cdot \nu_i \{i/\xi \}$.

Then, from $M \xrightarrow{\tau} \pi'$ and $d(M,N) < 1$, there is a distribution $\gamma''$ such that $N \xrightarrow{\tau} \gamma''$ with $K(d)(\gamma', \gamma'' \parallel (1 - |\gamma''\parallel)\text{Dead}) \leq d(M,N)$. Since $S_2 \in \text{inv} \parallel$, by Lemma 5 it follows that $N \cup O \xrightarrow{s(\cdot)} \gamma'' \parallel O$. Finally, we conclude that $\gamma'' \parallel O$ is the distribution $\gamma'$ we were looking for by $K(d)(\gamma', \gamma'' \parallel O \parallel (1 - |\gamma''\parallel)\text{Dead}) = K(d)(\gamma', \gamma'' \parallel O \parallel (1 - |\gamma''\parallel)\text{Dead}) = K(d)(\gamma', \gamma''(1 - |\gamma''|)\text{Dead}) \leq d(M,N) = d(M \cup O, N \cup O)$.

- $s$ is a sensor of $E_2$. In this case, the transition $P_1 \parallel P_2 \xrightarrow{s(\cdot)} \pi'$, where $\pi'$ is a process distribution such that $\pi = \pi' \parallel P_2$.

Assume $N = E_2; S_3 \parallel P_3$ with $E_3 = \langle \text{evol}^3, \text{meas}^3, \text{inv}^3 \rangle$ and $S_3 = \langle \xi_2^3, \xi_3^3, \xi_3^3 \rangle$. We show that rule (SensRead) allow us to infer $N \parallel \gamma'$ for some $\gamma'$.

By the rule (Par) we get $P_3 \parallel P_2 \xrightarrow{s(\cdot)} P_3 \parallel \pi'$. From $(S_1 \cup S_2) \in \text{inv}$, by definition of $E_1 \cup E_2$, we get both $S_1 \in \text{inv} \parallel$ and $S_2 \in \text{inv} \parallel$. Let $E_1 \cup E_3 = \langle \text{evol}, \text{meas}, \text{inv} \rangle$. From $d(M,N) < 1$ and $S_3 \in \text{inv} \parallel$, by Lemma 6 it follows that $S_3 \in \text{inv} \parallel$ and so $(S_3 \cup S_2) \in \text{inv} \parallel$. From $(\xi_1^3 \cup \xi_2^3)(s) = \sum_{i \in I} p_i \cdot v_i$, since $s$ is a sensor of $\xi_3^2$, we derive $\xi_2^2(s) = \sum_{i \in I} p_i \cdot v_i$. Hence we derive $(\xi_3^3 \cup \xi_2^3)(s) = \sum_{i \in I} p_i \cdot v_i$. 
The proof proceeds by case analysis on why Proposition 18. \( d \) in Proposition 14 instead of Proposition 13.

Proposition 16. \( d \) are immediate.

Proposition 15. \( d \) with \( N \) some transition \( M \). To prove the thesis it is enough to show that \( d \) by \( K(d)(\gamma', N \parallel \gamma') = K(d)(M, N) = d(M \parallel O, N \parallel O).\)

Also the \( n \)-weak bisimilarity metric is preserved by the parallel composition of physically disjoint CPSs.

**Proposition 14.** \( d^n(M \parallel O, N \parallel O) \leq d^n(M, N) \), for any physically disjoint CPS \( O \) and \( n \geq 0 \).

**Proof.** We proceed by induction over \( n \). The base case \( n = 0 \) is immediate since \( d^0(M, N) = 0(M, N) = 0 \) for all \( M, N \in \text{pCCPS} \). We consider the inductive step \( n + 1 \). The case \( d^{n+1}(M, N) = 1 \) is immediate, therefore we assume \( d^{n+1}(M, N) < 1 \). We have to show that any transition \( M \parallel O \overset{\alpha}{\rightarrow} \gamma \) is simulated by some transition \( N \parallel O \overset{\alpha}{\Rightarrow} \gamma' \) with \( K(d^n)(\gamma', N \parallel \gamma') = d^n(M \parallel O, N \parallel O) \). This can be shown precisely as in the proof of Proposition 13. Essentially, we have to replace all occurrences of \( d(M, N) \) by \( d^{n+1}(M, N) \) and all occurrences of \( K(d)(\gamma, \gamma') \) by \( K(d^n)(\gamma, \gamma') \).

Now we prove that our weak bisimilarity metrics are preserved by parallel composition of pure-logical processes. These are special cases of Proposition 13 and Proposition 14.

**Proposition 15.** \( d(M \parallel P, N \parallel P) \leq d(M, N) \), for any pure-logical process \( P \).

**Proof.** Let \( E_0 \) be the physical environment with an empty set of state variables, sensors and actuators. Let \( S_0 \) be the unique (empty) physical state of \( E_0 \). We have \( d(M \parallel P, N \parallel P) \leq d(M \parallel P, M \parallel (E_0; S_0 \times P) \parallel N \parallel P) \leq d(M \parallel (E_0; S_0 \times P) \parallel N \parallel P) \leq d(M \parallel (E_0; S_0 \times P) \parallel N \parallel (E_0; S_0 \times P)) \leq d(M \parallel N) \) where the first two inequalities follow by the triangular properties of \( d \), the last inequality follows by Proposition 13 and the two equalities are immediate.

**Proposition 16.** \( d^n(M \parallel P, N \parallel P) \leq d^n(M, N) \), for any pure-logical process \( P \) and \( n \geq 0 \).

**Proof.** The same arguments used in the proof of Proposition 15 apply. Essentially, we simply exploits Proposition 14 instead of Proposition 13.

Finally, we prove that weak bisimilarity metrics are preserved by channel restriction.

**Proposition 17.** \( d(M \backslash c, N \backslash c) \leq d(M, N) \), for any channel \( c \).

**Proof.** We reason as in Proposition 13. The case \( d(M, N) = 1 \) is immediate, therefore we assume \( d(M, N) < 1 \). Let us define the function \( d: \text{pCCPS} \times \text{pCCPS} \rightarrow [0, 1] \) by \( d(M \backslash c, N \backslash c) = d(M, N) \) for all \( M, N, O \in \text{pCCPS} \). To prove the thesis it is enough to show that \( d \) is a weak bisimulation metric. In fact, since \( d \) is the minimal weak bisimulation metric, this implies \( d \leq d \), thus giving \( d(M \backslash c, N \backslash c) \leq d(M \backslash c, N \backslash c) = d(M, N) \). To prove that \( d \) is a weak bisimulation metric, we show that any transition \( M \backslash c \overset{\alpha}{\rightarrow} \gamma \) is simulated by some transition \( N \backslash c \overset{\alpha}{\Rightarrow} \gamma' \) with \( K(d)(\gamma, \gamma' + (1 - |\gamma'|)\text{Dead}) \leq d(M \backslash c, N \backslash c) \). The proof proceeds by case analysis on why \( M \backslash c \overset{\alpha}{\rightarrow} \gamma \).

**Proposition 18.** \( d^n(M \backslash c, N \backslash c) \leq d^n(M, N) \), for any channel \( c \) and \( n \geq 0 \).
Proof. We reason as in Proposition 14. Hence, we proceed by induction over $n$, where the base case $n = 0$ is immediate and we consider the inductive step $n + 1$. The case $d^{n+1}(M, N) = 1$ is immediate, therefore we assume $d^{n+1}(M, N) < 1$. We have to show that any transition $M \xrightarrow{a} \gamma$ is simulated by some transition $N \xrightarrow{\alpha} \gamma'$ with $K(d^n)(\gamma, \gamma' + (1 - |\gamma'|)\text{Dead}) \leq d^{n+1}(M \setminus c, N \setminus c)$. The proof proceeds by case analysis on why $M \xrightarrow{a} \gamma$.

Proof of Theorem 3 By Propositions [13] [18]

Finally, as the bisimilarity $\approx$ coincides with the bisimulation metric $\approx_0$ it follows that Theorem 2 is a special case of Theorem 3. As consequence, the proof of Theorem 2 follows from Theorem 3.

Proof of Theorem 2 Consider Theorem 2.1. We have that

$$M \approx N \Rightarrow d(M, N) = 0 \Rightarrow d(M \uplus O, N \uplus O) = 0 \Rightarrow M \uplus O \approx N \uplus O$$

by applying, respectively, Proposition 6, Theorem 3.1, and Proposition 6 again. The proofs of Theorem 2.2 and Theorem 2.3 are analogous.

A.4 Proofs of Section 6

Proof of Proposition 9 The proof is analogous to that of Proposition 10 and Proposition 11 [1].

As the bisimilarity $\approx$ coincides with the bisimulation metric $\approx_0$ it follows that Proposition 3 is a special case of Proposition 9.

Proof of Proposition 3 Directly by Proposition 9.1 and Proposition 6.

Proof of Proposition 10 Define the CPS $\text{NIL}$ as $\text{NIL} = E_\emptyset; S_\emptyset \times \text{nil}$, where $E_\emptyset$ is the empty physical environment and $S_\emptyset$ the unique (empty) physical state of $E_\emptyset$. The only transition by $\text{NIL} \xrightarrow{\text{tick}} \text{NIL}$. By Proposition 1 and Theorem 1(d) we infer that $d^n(\text{Eng}_g, \text{NIL}) = 0$. Therefore, by the triangular property of $d^n$, to show the thesis $d^n(\text{Eng}_g, \text{Eng}_g) \leq 1 - (1 - q_g(p_g)^5)^n$ we can show $d^n(\text{NIL}, \text{Eng}_g) \leq 1 - (1 - q_g(p_g)^5)^n$.

The proof obligation $d^n(\text{NIL}, \text{Eng}_g) \leq 1 - (1 - (p_g)^5)^n$ follows from the following nine properties, by observing that the system $\text{Eng}_g$ satisfies the first one. In the following we denote the process $\text{RecY}.\text{tick}^5.\text{read}_S(x).[x > 10] \{\text{and warning}[ID].Y\}.\{\text{write cool}[off].\text{tick}\text{.Ctrl}\}$ with $\text{RecY}$.

1. $d^n(\text{NIL}, \text{Eng}_g; S \times P) \leq 1 - (1 - q_g(p_g)^5)^n$ whenever the physical state $S$ satisfies $\text{cool} = \text{off and temp } \in [0, 10.1]$, and the process $P$ is $\text{Ctrl}$, or $\text{tick}.\text{Ctrl}$.
2. $d^n(\text{NIL}, \text{Eng}_g; S \times P) \leq 1 - (1 - q_g(p_g)^5)^n$ whenever the physical state $S$ satisfies $\text{cool} = \text{off and temp } \in (10.1, 11.4]$, and the process $P$ is $\text{Ctrl}$, or $\text{Cooling}$.
3. $d^n(\text{NIL}, \text{Eng}_g; S \times P) \leq 1 - (1 - (p_g)^5)(1 - q_g(p_g)^5)^n$ whenever the physical state $S$ satisfies $\text{cool} = \text{off and temp } \in (10.4, 11.5]$, and the process $P$ is $\text{Ctrl}$, or $\text{Cooling}$.
4. $d^n(\text{NIL}, \text{Eng}_g; S \times P) \leq 1 - (1 - (p_g)^5)^n$ whenever the physical state $S$ satisfies $\text{cool} = \text{on and temp } \in (9.9, 11.4]$, and the process $P$ is $\text{RecY}$.
5. $d^n(\text{NIL}, \text{Eng}_g; S \times P) \leq 1 - (1 - (p_g)^5)(1 - q_g(p_g)^5)^n$ whenever the physical state $S$ satisfies $\text{cool} = \text{on and temp } \in (10.4, 11.5]$, and the process $P$ is $\text{RecY}$. 

...
6. \( d^n(NIL, Env; S \times P) \leq 1 - (1 - (p_g)^5)^k \) \((1 - q_g(p_g)^5)^n\), for all \( n \in [1, 4]\), whenever the physical state \( S \) satisfies \( cool = on \) and \( temp \in (11.4 - k(0.3), 11.5 - k(0.3))\), and the process \( P \) is
\[
P = \text{tick}^{5-k}.\text{read}_{s_t}(x)[x > 10]\{\text{snd warning}(ID).\text{RecY}\}, \{\text{write cool}(off).\text{tick.Ctrl}\}.
\]
7. \( d^n(NIL, Env; S \times P) \leq 1 - (1 - q_g(p_g)^5)^n \) whenever the physical state \( S \) satisfies \( cool = on \) and \( temp \leq 11.4 - k(0.3)\), and the process \( P \) is
\[
P = \text{tick}^{5-k}.\text{read}_{s_t}(x)[x > 10]\{\text{snd warning}(ID).\text{RecY}\}, \{\text{write cool}(off).\text{tick.Ctrl}\}
\]
for any \( k \in [1, 4]\).
8. \( d^n(NIL, Env; S \times P) \leq 1 - (1 - q_g(p_g)^5)^n \) whenever the physical state \( S \) satisfies \( cool = on \) and \( temp \leq 9.9\), and the process \( P \) is
\[
P = \text{read}_{s_t}(x)[x > 10]\{\text{snd warning}(ID).\text{RecY}\}, \{\text{write cool}(off).\text{tick.Ctrl}\}.
\]
9. \( d^n(NIL, Env; S \times P) \leq 1 - (1 - q_g(p_g)^5)^n \) whenever the physical state \( S \) satisfies \( cool = on \) and \( temp \leq 9.9\), and the process \( P = \text{write cool}(off).\text{tick.Ctrl} \).

We prove these nine properties in parallel, by induction over \( n \). The base case \( n = 0 \) is immediate since \( d^0 \) is the constant zero function \( 0 \). We consider the inductive step \( n > 0 \). First we observe that, given any distribution \( \sum_{i=1}^{n} p_i \cdot M_i \) over CPSs, the only matching \( \omega \in \Omega(\sum_{i=1}^{n} p_i \cdot M_i, NIL) \) is \( \omega(M_i, NIL) = p_i \). It follows that \( K(d^{n-1})(\sum_{i=1}^{n} p_i \cdot M_i, NIL) = \sum_{i=1}^{n} p_i d^{n-1}(M_i, NIL) \). We show only the first property, the other are analogous.

We distinguish the cases \( P = \text{Ctrl} \) and \( P = \text{tick.Ctrl} \).

- **Case \( P = \text{Ctrl} \).**
  The only transition by \( Env; S \times P \) is \( Env; S \times P \xrightarrow{\text{Ctrl}} \sum_{i=1}^{n} p_i \cdot M_i \), where \( M_i = Env; S \times P_i \), with either \( P_i = \text{tick.Ctrl} \) or \( P_i = \text{Cooling} \). The only transition by \( NIL \) is \( NIL \xrightarrow{\text{Ctrl}} NIL \). Therefore we infer \( d^n(Env; S \times P, NIL) \leq K(d^{n-1})(\sum_{i=1}^{n} p_i \cdot M_i, NIL) \). By the inductive hypothesis on \( d^{n-1}(M_i, NIL) \leq 1 - (1 - q_g(p_g)^5)^{n-1} \) in both cases, thus implying
\[
K(d^{n-1})(\sum_{i=1}^{n} p_i \cdot M_i, NIL) = \sum_{i=1}^{n} p_i d^{n-1}(M_i, NIL) \leq 1 - (1 - q_g(p_g)^5)^{n-1} \leq 1 - (1 - q_g(p_g)^5)^n.
\]
which completes the proof.

- **Case \( P = \text{tick.Ctrl} \).**
  The only transition by \( Env; S \times P \) is \( Env; S \times P \xrightarrow{\text{tick}} \text{next}_{Env}(S) \times \text{Ctrl} \). Again, the only transition by \( NIL \) is \( NIL \xrightarrow{\text{tick}} NIL \). Therefore \( d^n(Env; S \times P, NIL) \leq K(d^{n-1})(\text{next}_{Env}(S) \times \text{Ctrl}, NIL) \). By definition, \( \text{next}_{Env}(S) = \sum_{v \in [0.3, 1.1]} \frac{1}{[0.3, 1.1]_{v}} S[t \mapsto \xi_v(temp) - v] \). Hence in all physical states \( S' \) in the support of \( \text{next}_{Env}(S) \) we have \( cool = \text{off} \) and the temperature \( temp \) lies in the interval \([0 + 0.3, 10.1 + 1.4]\).

We have two cases: \( temp \in [0 + 0.3, 10.1] \), and \( temp \in (10.1, 10.5] \). If \( temp \in [0 + 0.3, 10.1] \), then by the inductive hypothesis on \( d^{n-1}(Env; S' \times \text{Ctrl}, NIL) \leq 1 - (1 - q_g(p_g)^5)^{n-1} \), for all \( S' \in \text{supp}(\text{next}_{Env}(S)) \), thus implying
\[
K(d^{n-1})(Env; \text{next}_{E}(S) \times \text{Ctrl}, NIL) \leq 1 - (1 - q_g(p_g)^5)^{n-1} \leq 1 - (1 - q_g(p_g)^5)^n.
\]
If \( temp \in (10.1, 10.5] \), then \( temp \in (10.4, 10.5] \) with a probability bounded by \( q_g \), whereas \( temp \in (10.1, 10.4] \) with a probability not less than \( 1 - q_g \). If \( temp \in (10.4, 10.5] \) we can apply the inductive hypothesis on item 3 to get \( d^{n-1}(Env_g; S' \triangleright Ctrl, NIL) \leq 1 - (1 - (p_g)^5)^n (1 - q_g(p_g)^5)^{n-1} \), for all \( S' \in \text{supp}(next_{Env_g}(S)) \). If \( temp \in (10.4, 10.5] \) we can apply the inductive hypothesis on item 2 to get \( d^{n-1}(Env_g; S' \triangleright Ctrl, NIL) \leq 1 - (1 - q_g(p_g)^5)^{n-1} \), for all \( S' \in \text{supp}(next_{Env_g}(S)) \). Therefore for some \( q \leq q_g \) we have

\[
K(d^{n-1}(Env_g; next_E(S) \triangleright Ctrl, NIL) = (1 - q) \left( 1 - (1 - q_g(p_g)^5)^{n-1} \right) + q \left( 1 - (p_g)^5 \right) (1 - q_g(p_g)^5)^{n-1}
\]

\[
= (1 - (1 - q_g(p_g)^5)^{n-1}) - q \left( 1 - (1 - q_g(p_g)^5)^{n-1} \right) + q \left( 1 - (p_g)^5 \right) (1 - q_g(p_g)^5)^{n-1}
\]

\[
= 1 - (1 - q_g(p_g)^5)^{n-1} - q + q \left( 1 - q_g(p_g)^5 \right)^{n-1} + q - (q - q_g(p_g)^5) (1 - q_g(p_g)^5)^{n-1}
\]

\[
= 1 - q + q - (1 - q - q - q_g(p_g)^5) (1 - q_g(p_g)^5)^{n-1}
\]

\[
= 1 - (1 - q_g(p_g)^5)^{n-1}
\]

\[
\leq 1 - (1 - q_g(p_g)^5) (1 - q_g(p_g)^5)^{n-1}
\]

\[
= 1 - (1 - q_g(p_g)^5)^n
\]

which completes the proof.

**Proof of Proposition 11** By Proposition 10 we derive \( d^n(Eng_g, \widehat{Eng_g}) \leq 1 - (1 - q_g(p_g)^5)^n = p \). By simple \( \alpha \)-conversion it follows that \( d^n(Eng^L_g, \widehat{Eng^L_g}) = p \) and \( d^n(Eng^R_g, \widehat{Eng^R_g}) = p \), respectively. By Theorem 3.4 (and the triangular property of \( d^n \)) it follows that \( d^n(Eng^L_g \sqcup \widehat{Eng^L_g} \triangleright \widehat{Eng^L_g} \sqcup \widehat{Eng^R_g}) \leq 2p \). By Theorem 3.5 it follows that

\[
d^n \left( (Eng^L_g \sqcup \widehat{Eng^L_g}) \parallel \text{Check}; (\widehat{Eng^L_g} \sqcup \widehat{Eng^R_g}) \parallel \text{Check} \right) \leq 2p.
\]

By Theorem 3.6 we obtain

\[
d^n \left( \text{Airplane}_g, \widehat{\text{Airplane}_g} \right) \leq 2p
\]

(2)

thus confirming that Proposition 11(1) holds.

Finally, by Equation 2 and Equation 1 we derive

\[
\lim_{g \to +\infty} d^n(\text{Airplane}_g, \widehat{\text{Airplane}_g}) \leq 2 \left( 1 - \left( \frac{1}{8^6} \right)^n \right).
\]

namely Proposition 11(2).
