Abstract

BACKGROUND: Importance of androgen receptor (AR) as an independent prognostic marker in Pakistani women with breast cancer (BCa) remains unexplored. Our aim was to identify the expression and potential prognostic value of AR, its upstream regulator (pAkt) and target gene (pPTEN) in invasive BCa. METHODS: This study used a cohort of 200 Pakistani women with invasive BCa diagnosed during 2002-2011. Expression of AR, pAkt and pPTEN was determined on formalin fixed paraffin embedded tissue sections by immunohistochemistry. The association of AR, pAkt and pPTEN with clinicopathological parameters was determined. Survival analyses were undertaken on patients with ≥ 5 years of follow-up (n = 82). RESULTS: Expression of AR, pAkt and pPTEN was observed in 47.5%, 81.3% and 50.6% of patients, respectively. AR-expressing tumors were low or intermediate in grade (P < .001) and expressed ER (P = .002) and PR (P = .001). Patients with AR+ tumors had significantly higher OS (Mean OS = 10.2 ± 0.465 years) compared to patients with AR− tumors (Mean OS = 5.8 ± 0.348 years) (P = .047). Furthermore, AR-positivity was associated with improved OS in patients receiving endocrine therapy (P = .020). Patients with AR+/pAkt+/pPTEN- tumors, had increased OS (Mean OS = 7.1 ± 0.535 years) compared to patients with AR−/pAkt+/pPTEN− tumors (Mean OS = 5.1 ± 0.738 years). CONCLUSION: AR-expressing tumors are frequently characterized by low or intermediate grade tumors, expressing ER and PR. In addition, expression of AR, pAkt and pPTEN, could be considered in prognostication of patients with invasive BCa.

Translational Oncology (2014) 7, 355–362

Introduction

Breast cancer (BCa) is the most common malignancy among women around the globe, and it is recognized to be the second most common cause of death in women [1]. Its rate is rising rapidly in Asian women and the developing world. According to the Surveillance, Epidemiology, and End Results database, Asian Indian/Pakistani women residing in the United States seem to have a higher frequency of BCa particularly at a younger age (< 40 years) compared to Caucasians [2]. The data from South Karachi, a pragmatic representative of the population of Pakistan, revealed that BCa accounted for approximately one third of cancers in women [3].

Hormone receptors such as estrogen (ERs) and progesterone receptors (PRs) play a seminal role in determining the treatment strategy and prognosis of patients with BCa. In addition, human epidermal growth factor receptor type 2 (HER2) has been found to be overexpressed in a subset of invasive BCa and is associated with poor prognosis [4,5]. According to Surveillance, Epidemiology and End Results database, Asian Indian/Pakistani women residing in the United States had more ER/PR-negative BCa (30.6%) compared to Caucasians (21.8%) [2]. These data are similar to studies undertaken on samples of BCa from women residing in Pakistan that showed that...
60% to 65% of the tumors expressed ER/PR [6,7]. Furthermore, frequency of HER2 expression has also found to be higher in Pakistani women with BCa (30%-39%) [6,8,9] in contrast to Caucasians (25%-30%) [4,5].

Only a limited number of studies have evaluated the role of the androgen receptor (AR), phosphorylated Akt (pAkt), and phosphorylated phosphatase and tensin homolog (pPTEN) as potential predictive or prognostic markers compared to the large number of studies on ER, PR, and HER2.

AR is a ligand-dependent transcription factor; its expression on BCa is known to be linked with improved survival [10–12]. Hu et al. assessed AR status in a large (n = 1467) cohort of patients with BCa; they found 91% and 86% 5-year survival in patients with AR-positive and AR-negative tumors, respectively [11], whereas other studies have not found a similar association with survival [13,14]. AR expression has been observed in approximately 40% to 80% of BCas [11,15–19]. Although a significant number of patients with BCa express AR, the underlying molecular mechanisms of AR signaling pathway in BCa biology have not been intensely studied, and the role of AR on survival in patients with BCa needs further delineation.

Protein kinase B (more commonly referred as Akt) is a serine/threonine kinase, which plays a role in BCa growth by promoting cell survival and inhibiting cell death [20,21] and is being considered as a potential target for BCa therapy [22,23], whereas PTEN, a well-recognized tumor suppressor gene, negatively regulates Akt and has been shown to inhibit BCa growth [24,25]. Nagata and colleagues reported loss of PTEN in 50% of patients with BCa [26]. AR has been shown to increase PTEN expression by activating its promoter that in turn lowers Akt activity and decreases cellular proliferation in BCa [27]. Wang et al. also reported that AR increases PTEN expression and inhibits Akt phosphorylation in BCa cells [28]. PTEN is a positive modulator, whereas Akt is a negative modulator of AR transcriptional activity. The cross talk of AR signaling with Akt and PTEN may have clinical significance in the development of BCa has not been well studied, though the expression of Akt and PTEN in BCa tissue has been reported [29–31].

To our knowledge, to date, no studies have been undertaken examining the expression of AR, active form of Akt (pAkt), and stable form of PTEN (pPTEN) on BCa in a cohort of Pakistani women. In this study, our aim was to determine the immunohistochemical expression of AR, pAkt, and pPTEN in Pakistani women with invasive BCa and their role as potential prognostic markers. We also examined the significance of AR expression on patient’s survival after stratifying by ER, pAkt, and pPTEN status and endocrine treatment.

Materials and Methods

Patients and Setting

A total of 1103 patients were diagnosed with invasive BCa and treated at the section of breast diseases, Aga Khan University Hospital (Karachi, Pakistan), during 2002 to 2011. From a total of 1103 cases, 200 were selected for this study on the basis of the following criteria: 1) availability of formalin-fixed paraffin-embedded (FFPE) tissue blocks, 2) sufficient representative area of primary tumor in FFPE blocks, and 3) complete follow-up data. Demographical data, details of treatment regimen, clinicopathologic parameters including tumor size and type, ER/PR/HER2 status, grade, and lymph node status, and clinical follow-up were obtained by reviewing medical records. To minimize the selection bias, we compared the clinicopathologic characteristic between patients who were selected for this study (n = 200) with those who were not selected (n = 903), and no statistically significant difference was found between the two groups. All patients had previously consented for use of their tissues and clinicopathologic data for research.

Five-micron serial sections were cut from FFPE BCa tissue blocks. At least one section was stained with hematoxylin and eosin, assessed by a pathologist, and compared to original report. The study was approved by the Ethical Review Committee of the Aga Khan University (2390-RO-ERC-12).

Survival analysis was performed on a subgroup of patients with BCa who had follow-up of at least 5 years or more (n = 82). Patients diagnosed during 2002 to 2008 and followed up until December 2013 or death were included for survival analysis. Overall survival (OS) was calculated from the date of diagnosis to the date of last follow-up or death due to any cause.

Immunohistochemical Expression of AR, pAkt, and pPTEN

Immunohistochemistry was performed on FFPE sections to assess the expression of AR, pAkt, and pPTEN as described previously with some modifications [32–34]. Dako REAL EnVision Detection System, Peroxidase/DAB+, Rb/Mo (Dako, Glostrup, Denmark) was used for immunohistochemical staining. Briefly, 5-μm serial sections were cut from FFPE tissue onto Superfrost slides (Thermo Scientific, Braunschweig, Germany). Sections were deparaffinized in xylene (BDH, Poole, UK) and rehydrated in a graded series of ethanol (Merck, Darmstadt, Germany). Heat-induced antigen retrieval was performed in 10 mM citrate buffer (pH 6.0) for AR (1 hour), pAkt, and pPTEN (30 minutes) in a boiling water bath (Grant Instruments Ltd., Cambridge, UK). Endogenous peroxidase activity was blocked by immersing slides in 0.3% vol/vol H2O2 at room temperature (RT; 25°C) for 10 minutes. Next, anti-human AR antibody (mouse monoclonal IgG, clone AR441; Dako, diluted 1:50) was applied for 4 hours at RT, and anti-human Ser473 pAkt/1/2/3 (rabbit polyclonal IgG; Santa Cruz Biotechnology, diluted 1:50) and Ser340/Thr342/343 pPTEN (rabbit polyclonal IgG; Santa Cruz Biotechnology (Santa Cruz, CA), diluted 1:50) were applied for overnight at 4°C onto serial tissue sections from each case. After three washes for 5 minutes each in phosphate-buffered saline (pH7.4) (Gibco, Carlsbad, CA), HRP-labeled secondary antibody was applied for 1 hour at RT. After washing, substrate was added, and DAB was used for visualization. Hematoxylin (BDH) was used for counterstaining, and images were obtained using microscope (Olympus BX41, Tokyo, Japan, DP70 camera). Negative (primary antibody replaced by phosphate buffer saline) and positive (a known BCa tissue section positive for AR, pAkt, pPTEN) controls were included with each run. Our experimental methodology including antigen retrieval, choice of the antibody, and detection system was in concordance with previously reported studies.

Scoring

Stained sections were scored by a pathologist who was masked for patient’s clinicopathologic parameters and outcomes. Slides were scored using Allred guidelines [35]. In brief, entire slide of each sample was evaluated using Olympus BX41 microscope at ×100 and ×200 magnifications. First, proportion of positively stained tumor cells (0, none; 1, <1/100; 2, 1/100 to 1/10; 3, 1/10 to 1/3; 4, 1/3 to 2/3; and 5, >2/3) was estimated. Next, an intensity score that represented the average intensity of positive tumor cells (1, weak; 2, intermediate; and 3, strong) was estimated. The proportion and intensity scores were then added
to obtain a total score, which ranged from 0 to 8. Nuclear staining for AR and cytoplasmic staining for pAkt and pPTEN with a total score of ≥3 were considered positive.

Statistical Analysis

Frequencies of different markers including AR, pAkt, and pPTEN with 95% confidence intervals (CIs) were generated for the expression of these markers. Descriptive statistics was determined for continuous (mean ± SE) and categorical (percentages) variables. The associations of AR, pAkt, and pPTEN expression with demographical data, details of treatment regimen, and clinicopathologic parameters like tumor type, grade, size, status of lymph node, ER, PR, and HER2 were assessed by χ² test if appropriate; otherwise, Fisher exact test was applied. OS were computed using Kaplan-Meier method. Means and SE of OS time were reported for clinicopathologic parameters. The association of different survival times by these markers was obtained using log-rank test. A P value < .05 (two sided) was considered statistically significant. SPSS (version 18.0, IBM Company, Chicago, IL) was used for all statistical analysis.

Results

Patients and Tumor Characteristics

Mean (± SE) age of patients at diagnosis was 54.8 (± 10.5) years, of which 39% were younger than 50 years. Most of the tumors (95.5%) were ductal, followed by lobular (3%) and mucinous carcinomas (1.5%). More than half of the tumors (56.5%) were of grade II, 54.5% of tumors were 2 to 5 cm in size, and 53.0% of the primary tumors had no lymph node involvement at diagnosis. Among 121 cases of ER-positive tumor, 115 (95%) patients received endocrine therapy. Majority of them (89.5%) received tamoxifen as first option, whereas the remainder (10.5%) received either Femara (Novartis, Basel, Switzerland) or Arimidex (ICI Pakistan Ltd., Karachi, Pakistan).

Expression of AR, pAkt, and pPTEN

Expression of AR, pAkt, and pPTEN was observed in 47.5% (95% CI = 40.6%-54.4%), 81.3% (95% CI = 75.4%-87.2%), and 50.6% (95% CI = 42.9%-58.3%) of patients, respectively.

Table 1. Relative Percentage of Expression of AR, pAkt, pPTEN, ER, PR, and HER2 from Different Studies in Invasive BCa.

| Marker | Current Study (%) | Other Studies in Pakistani Population (%) | Caucasians (%) |
|--------|------------------|------------------------------------------|----------------|
| AR     | 47.5             | None                                     | 70-80          |
| pAkt   | 81.3             | None                                     | 76-81          |
| pPTEN  | 50.6             | None                                     | 49-52          |
| ER/PR  | 56               | 60-65 [6.7]                              | 55-70 [38.39]  |
| HER2   | 24               | 30-39 [6,8,9]                            | 25-30 [4,5]    |

AR, androgen receptor; pAkt, phosphorylated Akt; pPTEN, phosphorylated phosphatase and tensin homolog; ER, estrogen receptor; PR, progesterone receptor; HER2, human epidermal growth factor receptor type 2.

Figure 1. Immunohistochemical expression of AR, pAkt, and pPTEN in invasive breast carcinoma. (A) Heterogeneous nuclear AR, (B) cytoplasmic pAkt, and (C) pPTEN protein expression in a tumor. Images are at × 200, and insights are at × 400 magnification.
Expression of AR was significantly associated with increasing age (≥ 50 years ($P = .040$), low or intermediate grade (I and II) tumors ($P = .001$), expression of ER ($P = .002$), PR ($P = .001$), and therapeutic modalities including endocrine ($P = .004$) and chemotherapy ($P = .015$). There were no significant differences observed between AR expression and tumor size, lymph node involvement, HER2 status, tumor type, radiation therapy, and expression of pAkt and pPTEN (Table 2).

### Overall Survival

Survival analysis was performed on 82 patients who had been followed for five or more years. A total of 16 deaths were reported during this period. The mean OS time was 9.2 ± 0.41 years, and lost to follow-up was 17% ($n = 14$) only.

### AR expression and survival

Women with AR-expressing or positive tumors had significantly higher OS (mean OS = 10.2 ± 0.465 years) than women whose tumors did not express AR (mean OS = 5.8 ± 0.348 years) ($P = .042$; Figure 2A). Lymph node involvement showed a significant ($P = .043$) association with lower OS. Patients with large tumor size (mean OS = 0.69) and positive pAkt status ($P = .243$) tended to also have decreased OS (Table 3).

### Relationship between AR/pAkt expression and survival

To compare the potential prognostic value of AR and ER coexpression on survival, patients were categorized into the following four groups: 1) AR+/ER− ($n = 19$), 2) AR+/ER+ ($n = 16$), 3) AR−/ER+ ($n = 10$), and 4) AR−/ER− ($n = 37$). Although survival analyses showed no significant OS difference among the four groups ($P = .214$), women with AR+/ER+ tumors showed a trend for a better OS (mean OS = 5.0 ± 0.257 years) compared to the AR−/ER− (mean OS = 4.4 ± 0.573 years) subgroup. We also found a survival advantage of AR expression in the AR+/ER− group with only 12.5% deaths (2 of 16), compared to 27% (10 of 37) deaths in patients with AR−/ER− tumors ($P = .214$; Figure 2B).

### Relationship between AR/pPTEN expression and survival

The association of AR expression with OS in the subgroup of patients receiving endocrine therapy was investigated ($n = 26$). In this subgroup, patients with AR-positive tumors showed significantly better OS compared to patients whose tumors did not express AR ($P = .020$; Figure 2C).

### Relationship between AR/pAkt expression and survival

The association of AR with pAkt-positive patients ($n = 58$) was determined, and we found that patients whose tumors expressed both pAkt and AR (AR+/pAkt+) had better OS compared to women with AR−/pAkt+ tumors ($P = .037$; Figure 2D).

### Relationship between AR/pAkt/pPTEN combinational groups and survival

The implications of AR expression on disease outcome were assessed in pAkt+/pPTEN− ($n = 31$) tumors. Although survival analyses showed that there was no significant OS difference between patients with AR+/pAkt+/pPTEN− ($n = 18$) and AR−/pAkt+/pPTEN− ($n = 13$) tumors ($P = .114$), women with AR+/pAkt+/pPTEN− tumors had relatively higher OS (mean OS = 7.1 ± 0.535 years) compared to women with AR−/pAkt+/pPTEN− tumors (mean OS = 5.1 ± 0.738 years) (Figure 2F).

### Discussion

The expression of AR in this study, as determined by immunohistochemistry, demonstrated that 47.5% (95 of 200) of invasive BCa tumors, from a Pakistani cohort, expressed nuclear AR. This is similar to other reported studies, where the percentage of AR-positive tumors
ranges from 40% to 80% [11,17–19]. This wide range may reflect genuine biologic variations, arising due to environmental and genetic diversity across the globe.

In the current study, tumors that expressed AR were of low or intermediate grade (grades I and II) and expressed ER and PR, which is consistent with previous studies [11,33]. We also found that AR expression in tumors was significantly associated with longer OS, with a survival advantage of 4.4 years, in comparison to women whose tumors did not express AR. Our data are consistent with previous studies that have assessed AR expression in BCa and its potential as an
Table 3. Survival Analysis (Kaplan-Meier and log-rank test) and Significance of AR, pAkt, Tumor Size, Grade, and Node Involvement.

| Factors           | N  | Mean OS in Years (±SE) | P Value |
|-------------------|----|------------------------|---------|
| AR                |    |                        |         |
| Negative          | 47 | 5.8 (±0.35)            | .042*   |
| Positive          | 35 | 10.2 (±0.46)           |         |
| pAkt              |    |                        | .243    |
| Negative          | 14 | 10.4 (±0.57)           |         |

| N0                | 44 | 9.5 (±0.53)            |         |
| N1                | 20 | 8.6 (±0.40)            |         |
| N2                | 8  | 4.7 (±0.68)            |         |
| N3                | 8  | 3.9 (±0.52)            |         |

* Statistically significant; N, number of patients; SE, standard error.

Additionally, an in vitro study has found that aromatase inhibitors have a greater antiproliferative effect on AR+/ER+ BCa cell line. The inhibitory effect may have been due to inhibition of estrogen synthesis and activation of the intracellular AR signaling, caused by sustained androgen levels [51]. Taken together, these findings suggest that AR expression could be an additional significant marker for endocrine responsiveness in ER-positive cancers.

Role of PTEN as a negative regulator of Akt signaling pathway is well recognized, and these two variables are found to be inversely related with each other [52,53]. To date, little is known about the AR-mediated regulation of Akt and PTEN expression. Therefore, we determined AR status along with pAkt and pPTEN in the same cohort of patients with BCa and analyzed the potential prognostic significance of AR in patients stratified by pAkt and pPTEN status. We found expression of pAkt and pPTEN in 81.3% and 50.6% of invasive BCa, respectively. We did not find independent association of pAkt or pPTEN expression with any clinicopathologic characteristics or survival, which is in contrast to previous studies showing association of activated Akt and loss of PTEN with poor survival [30,37]. Absence of independent prognostic significance of pAkt and pPTEN in our study could be due to the ethnic background of the patient population and/or the number of patients studied.

To date, a very limited number of studies have examined the expression of AR/Akt/PTEN and their association or cross talk in BCas. Wang et al. reported positive correlation between AR and PTEN expression in BCa tissues [27]. Aleskandarany et al. also demonstrated a direct correlation of pAkt expression with AR status in invasive BCa [34]. Conversely, Lin et al. described an inverse relationship between Akt and AR signaling pathways, indicating that Akt inactivates AR [54] and promotes AR degradation [55] that resulted in suppression of AR-induced apoptosis. A few in vitro studies showing the related role of Akt, PTEN, and AR in BCa suggest that AR lowers Akt activity and increases PTEN expression that in turn decreases BCa cell proliferation [27,28]. Collectively, these studies suggest that PTEN-Akt is a complex signaling pathway, operated under multiple levels of feedback; AR pathway is known to be involved in this feedback loop and has been shown to downregulate Akt and upregulate PTEN expression.

Unlike previous studies, we did not find any association between expression of pAkt and pPTEN with AR status. This suggests presence of mechanisms other than AR that might be responsible for regulating Akt/PTEN expression. However, we found that expression of AR was associated with significantly longer OS in patients with pAkt-positive tumors, suggesting protective role of AR in these patients. We also found a survival advantage with only 7.1% deaths in patients with AR+/pPTEN+ tumors, whereas loss of expression of both markers was found to be associated with lower OS with 32% deaths. These results suggest that AR-PTEN coexpression might be decreasing the cellular proliferation and increasing apoptosis (action mediated by pAkt), resulting in increased OS in the subset of patients with AR+/pPTEN+ tumors.

Reportedly, patients with Akt+ and PTEN- tumors have been shown to exhibit worst survival; however, these patients were not stratified into AR-positive and AR-negative groups [31]. We stratified tumors in context of combined expression of pAkt and pPTEN and determined the impact of AR expression on survival in patients with pAkt+/pPTEN- tumors. We found that, in a subset of women with pAkt+/pPTEN- tumors, expression of AR conferred a survival
advantage, whereas loss of AR reduced the survival. Our results suggest that AR, independent of its coexpression with pPTEN, could be negatively regulating Akt-mediated proliferative effect as shown by survival advantage of 2 years in patients with AR+/pAkt−/pPTEN− tumors when compared with AR−/pAkt+/pPTEN+ tumors. This did not reach to statistical significance possibly due to low number of patients (n = 31) in this subset (Figure 2D). The mechanism of these important observations where AR appears to negate the proliferative and antiapoptotic effect due to activation of Akt and loss of PTEN, respectively, warrants further study.

In the current study, survival analysis was limited to patients who went through a follow-up of 5 years or more (n = 82). A distinctly better survival was observed not only in patients with AR expression for whom we had 5-year follow-up but also in patients whose follow-up was between 2 to 11 years (n = 200, data not shown). However, relatively small number of deaths (n = 16) restricted us to perform multivariable analysis.

In conclusion, we found that, in a cohort of Pakistani women with BCa, expression of AR conferred a survival advantage independent of other markers. Furthermore, expression of AR in pAkt+/pPTEN− subgroup could be useful in distinguishing BCa with more favorable prognosis. Future studies on larger cohort of patients would be helpful in establishing the role of AR, pAkt, and pPTEN expression as significant independent prognostic and predictive factors in patients with BCa.

Acknowledgments

We are thankful to Aga Khan University for financial and technical support, the Department of Pathology and Microbiology (Zubair Ahmed) for assisting with retrieval of archival blocks, Amna Rehana Siddiqui from King Saud University for reviewing the manuscript and helpful suggestions, and all patients who contributed tissue specimen blocks that were used in the study.
