Machine Learning (ML) delivers an accurate and quick prediction outcome and it has become a powerful tool in health settings, offering personalized clinical care for stroke patients. An application of ML and Deep Learning in health care is growing however, some research areas do not catch enough attention for scientific investigation though there is real need of research. Therefore, the aim of this work is to classify state-of-arts on ML techniques for brain stroke into 4 categories based on their functionalities or similarity, and then review studies of each category systematically. A total of 39 studies were identified from the results of ScienceDirect web scientific database on ML for brain stroke from the year 2007 to 2019. Support Vector Machine (SVM) is obtained as optimal models in 10 studies for stroke problems. Besides, maximum studies are found in stroke diagnosis although number for stroke treatment is least thus, it identifies a research gap for further investigation. Similarly, CT images are a frequently used dataset in stroke. Finally SVM and Random Forests are efficient techniques used under each category. The present study showcases the contribution of various ML approaches applied to brain stroke.

application of ML-based methods in brain stroke. To the
best of our knowledge there is no detailed review about
the application of ML for brain stroke. In the Section 2,
we review some literature about ML and brain stroke
field whereas, Section 3 presents the study design and
selection, search strategy, and categorization of the
studies per category. Section 4 explains outcomes of the
studies by each category. Finally, Section 5 discusses
insights of reviewed studies.

Background

Machine Learning

This section provides a brief overview of ML sub
types. ML is a crucial branch of Artificial Intelligence
(AI). ML is the study of algorithms that have the ability
to learn and improve from past data without being
explicitly programmed. There are several sub types of
ML, however in this review, we focus on supervised
learning, unsupervised learning and deep learning are
focused types in the current study. Supervised learning
trains a model that maps an input to an output based
on observations and predicts the output. It is categor-
ised into classification and regression. Classification
[23] is to classify discrete target variable using predic-
tors. Logistics Regression (LR) [41], naive bayes classi-
fier [37], Support Vector Machines (SVM) [10] are some
classification techniques. Regression investigates the
relationship between numerical target variable and pre-
dictors. The study [24] has done extensive experimental
analysis of 77 regression techniques from 19 ML fami-
lies over 84 datasets. Unsupervised learning [22] is used
to group the observations for making clusters based on
their similarity. Clustering [70], association analysis
and dimensionality reduction are types of unsupervised
learning [1,20,59]. Deep learning (DL) develops a
computational model [44] with multi-processing layers
to learn a data progressively from raw input. Some DL
architectures are Convolutional Neural Networks
(CNN) and Recurrent neural network (RNN) and they
are mostly used to solve image processing [63] prob-
lems. Some of the top applications of DL are self-driv-
ing cars, natural language processing, fraud detection,
health care, etc. Eventually, ML has a great implementa-
tion in the several fields like medicine, social network-
ing, agriculture, sales and marketing, environmental
science, etc. using several ML algorithms.

Stroke

Stroke consists of a heterogeneous group of disorders
characterized by a sudden and focal disruption of the
brain’s vascular supply, causing neurologic symptoms
that persist more than 24 hours [33]. Broadly, strokes can
be classified as either ischaemic, which are the most com-
mon, happening in approximately 85% of the cases, or
haemorrhagic. Ischaemic strokes occur when blood ves-
sels are occluded by a thrombus or an embolus, resulting
in brain ischemia [31]. Haemorrhagic strokes are caused
by the rupture and bleeding of a weakened blood vessel
into the surrounding brain tissue, which normally leads
to intracranial pressure [31]. There are many risk factors
that can precipitate a stroke; these can be categorized as
non-modifiable and modifiable. The first set of risk factors
include age, gender, race and ethnicity. In contrast, modi-
fiable risk factors are related to clinical conditions, such as
cardiac diseases (e.g., hypertension, atrial fibrillation,
hypercholesterolemia) and diabetes mellitus, and life-style factors, namely sedentarism, obesity, poor nutrition, tobacco use and alcohol consumption [16,53]. Early identification and better control of modifiable risk factors is determinant for stroke prevention and to avoid the latter development of vascular dementia [58]. Stroke diagnosis involves a detailed medical history, a physical and neurological examination, and a brain imaging test (e.g., computed tomography (CT) scan or magnetic resonance imaging (MRI)) in order to rule out other stroke mimics (e.g., brain tumors, subdural hematomas) and to determine the type of stroke, its location and the extent of the brain injury [64]. Treatment will depend on the cause and severity of the stroke and it can include surgical procedures (e.g., thrombectomy in case of ischemic stroke), specific medication to dissolve blood clots (e.g., thrombolytic therapy for ischaemic strokes) or to manage cardiovascular risk factors (e.g., statins used in the treatment of hypercholesterolaemia) and rehabilitation (e.g., motor and neurocognitive) [15,42,66]. It is important to note that since poststroke survival rate is increasing, stroke patients tend to live longer with innumerable sequelae, which are not only physical, but also cognitive and emotional, and negatively influence their quality of life and functionality. Despite this fact, rehabilitation after stroke is still primarily directed towards motor function and, therefore, should follow an interdisciplinary and holistic approach in order to overcome and/or mitigate the multidimensional post-stroke impairments [30,33]. Finally, prognosis prediction following stroke is extremely relevant, namely in treatment selection (e.g., identifying which patients will benefit from a specific type of treatment), in determining long-term outcomes (e.g., motor, cognitive, functional) and in planning rehabilitation by establishing appropriate goals, in light of the previous outcome predictions, and redefining unrealistic expectations that could hamper the patient’s motivation and engagement in the rehabilitation process [8,61].

Methodology

Study Design

The goal of the present study is to review the contribution of ML in solving some stroke-related problems (e.g., i.e., prevention/risk factor identification, diagnosis, treatment and prognostication). It considers the most systematic approach because it reviews best of studies and writes a result and discussion with some interesting insights, get from all studies which are definitely valuable for further investigation.

Search Strategy

We analysed studies from 2007 to 2019, in fact all available studies. Studies were identified from the results of ScienceDirect web scientific database. Below search term was searched in the research title, abstract or author-specified keywords of ScienceDirect database. "machine learning" AND "stroke"

Study Selection

Study selection was done with the help of a Psychology expert. We identified a total of 74 studies, accessed on 7th November 2019; 73 studies were written in English and 1 was written in Spanish. We have only considered studies written in English. We excluded 34 studies that were not related to our topic (e.g., pen stroke, stroke trajectories in a hand drawn pen-and-ink hatching, Chinese character recognition, electric power systems, that document images, Alzheimer’s disease, osteoporosis detection, composition and declarative gesture description, estimation of mass damper parameters, monitor physical activity in children, and more). Therefore, after checking the relevance of each study, we included 39 studies in the review. All included studies were then analyzed individually, considering 8 research questions, specified in the Table 1:

Table 1. Research questions to analyze each study one-by-one.

| Question                                                                 | Answer |
|--------------------------------------------------------------------------|--------|
| (1) Which was the stroke problem addressed?                               |        |
| (2) What was the ML or DL approach employed?                              |        |
| (3) Which features were used?                                            |        |
| (4) How many samples were used?                                          |        |
| (5) What were the classes used?                                          |        |
| (6) Is there any pre-processing like feature selection, data augmentation, etc.? |        |
| (7) What were the performance metrics used?                              |        |
| (8) What are the clinical implications?                                   |        |
Stroke Prevention

In this category, we have considered studies that focus on the early detection or identification of stroke; some studies mention important stroke risk factors and post-stroke complications, namely familiar hypercholesterolemia, atherosclerosis, body max index and cerebral edema, respectively, while others refer to specific techniques that can aid stroke detection, such as genome-wide transcriptional profiling and the use of spiking neural networks.

Table 3 shows 8 stroke prevention studies, ML approach to solve those problems, features, number of samples, results achieved by ML approach and lastly, clinical implications. Familial hypercholesterolemia is a genetic condition characterized by the presence of a high amount of low-density lipoprotein (LDL), which can lead to premature heart disease and stroke. Since most individuals with familial hypercholesterolemia remain undiagnosed,[55] aimed to predict the familial hypercholesterolemia score (responsible for early detection of heart-related injuries) using[14] Random Forest (RF). The FIND FH model (or RF model) parameter optimization was done by 5-fold cross validation and got precision of 0.85 and recall 0.45, shown in the Table 3. Similarly, carotid-artery atherosclerosis (CA) can also increase the risk of ischaemic strokes due to the accumulation of plaques in the carotid arteries - the main supply of blood to the brain. SVM was used for 4-class classification problem[11] with the aim of classifying subjects with CA from magnetic resonance images. Cerebral edema is a major poststroke complication that is associated with high mortality. Considering that, RF model was developed[18] for the segmentation of cerebrospinal fluid on Computed Tomography (CT) scan images and concluded that RF is better than Hounsfield Unit thresholding. This approach accomplished an accuracy rate of 97.5%. For stroke monitoring, carotid intima-media thickness (cIMT) is used as an important biomarker. Study[12] presented 2-level DL based system for cIMT measurements. In the first level, feature extraction and image segmentation were done and second layer consisted of ML regression for smoothing the raw inner lumen and outer interadventitial borders which are used for the cIMT measurements. Additionally,[51] proposed a fully automatic strategy by identifying the Intima-Media Thickness boundaries from ultrasound common carotid artery images using Artificial Neural Networks (ANN) and training computational time is 1.4s. Genome-wide transcriptional profiling can be useful in stroke detection. Study[56] identified a 10-gene pattern of differential expression using ML technique (here, genetic algorithm/kNN) which has enough ability for stroke detection.

The study[40] presented personalised modelling of spatio or spectro-temporal data (SSTD) and early prediction of stroke events for each individual by using Spiking Neural Networks (SNN) with accuracy 94%. Last but not least, Body Mass Index (BMI) is a good indicator of early stroke prediction thus, the study[45] classified BMI status into three classes (normal, overweight and obese) on imbalanced data by LR, bagging and RF ensemble techniques.

Stroke Diagnosis

This section includes a total of 18 studies about stroke diagnosis. Table 5 and 4 present 18 objectives on stroke diagnosis, ML techniques, features, sample size, result of optimal ML model and clinical implications. MRI and CT scans are frequently used in stroke diagnosis. Bio-imaging is an important process in stroke classification or lesion extraction because it identifies the damaged area of the brain, thus more studies focus on this problem to achieve high precision. To target this problem, [57] presented a new approach to the classification of stroke subtypes, specifically haemorrhagic and ischaemic strokes, using SVM,

Table 2. List of performance measures involved in 39 studies.

1. **Classification Accuracy**: It is the fraction of the number of correct predictions by the total number of predictions.
2. **Precision**: It is also known as positive predictive value, It shows the correctness achieved in positive prediction.
3. **Recall or sensitivity**: It is the fraction of the total amount of relevant instances that were actually retrieved.
4. **Precision-recall curve**: It shows the trade-off between the true positive rate and the positive predictive value for a classifier at all classification thresholds.
5. **Specificity**: It is the measure of negative examples labeled as negative by classifier.
6. **F-score**: It is a weighted average of the recall and precision.
7. **Receiver Operating Characteristic (ROC)**: It is a trade-off between the true positive rate and the false positive rate for a classifier at all classification thresholds.
8. **Area Under the Curve (AUC)**: It measures the entire 2D area underneath the entire ROC curve.
9. **Negative predictive value**: It is the fraction of number of true negatives and number of negative calls.
10. **Paired t-test**: It is used to compare two population means from the same unit or subject.
11. **Root Mean Square Error (RMSE)**: It can be considered as the standard deviation of residual.
12. **Correlation (R)**: It shows the relationship between pairs of variables.
13. **Coefficient of determination (R²)**: It is the proportion of the variance in the output variable that is predictable from the input variables.
14. **Computational time**: It is the amount of time required to perform computational processes.

| Sr. No | Objective                                                                 | Reference | ML-based approach | Samples | Features                                      | Optimal Results                          | Clinical Implications                                      |
|-------|---------------------------------------------------------------------------|-----------|-------------------|---------|-----------------------------------------------|------------------------------------------|---------------------------------------------------------------------------------------------------------------|
| 1     | Identify subjects with Carotid-artery Atherosclerosis (CA) from a heterogeneous cohort of magnetic resonance brain images | [11]      | SVM               | 401     | MRI images                                   | SVM ACC = 97.5%                           | Early identification of patients with CA will help prevent ischemic stroke by providing the proper diagnosis and treatment. |
| 2     | The carotid intima-media thickness (cIMT), Biomarker for cardiovascular diseases and stroke monitoring. Measuring the cIMT can help prevent and manage cardiovascular diseases (CDV) that may lead to stroke. | [12]      | DL for segmentation, ML-based joint coefficient method | 203     | 396 B-mode ultrasound images of the right and left common carotid artery | Error on test set DL1 = 0.126 ± 0.134  \text{DL2 = 0.124 ± 0.100mm} | Measuring the cIMT can help prevent and manage cardiovascular diseases (CDV) that may lead to stroke. |
| 3     | Develop an automated technique for cerebrospinal fluid (CSF) segmentation via integration of RF with geodesic active contour (GAC) segmentation | [18]      | RF                | 38      | Serial Computed Tomography (CT) images       | paired t-test: p < 10^{-3} in baseline p < 10^{-5} in early follow-up | Early identification of patients at risk of developing malignant cerebral edema, which is a major complication following ischemic stroke. |
| 4     | Develop method and system for personalised modelling of Spatio/Spectro-Temporal data (SSTD) and prediction of events. | [40]      | Spiking neural networks (SNN) | 40      | SSTD                                          | ACC = 94%                                 | Developed PMeSNNr framework provides much higher accuracy than conventional ML methods |
| 5     | Prediction of body mass index status from voice signals using ML                                                                 | [45]      | LR, bagging and RF | 1,568   | voice features                                | LR on imbalanced data AUC = 0.569-0.731 | Estimating the body mass index (BMI) through voice signals can enhance early identification and detection of people at risk of having a stroke or other clinical conditions (e.g., CDV and diabetes). |
| 6     | An early diagnosis of atherosclerosis                                                                                         | [51]      | ANN               | 55      | B-mode ultrasound images                      | computation time per processed image: time = 1.4s | Assessing the intima-media thickness (IMT) of the common carotid artery (CCA) can contribute to |

(Continued)
Multi-Layer Perceptron (MLP), minimal learning machine, Linear Discriminant Analysis (LDA), and Structural Co-Occurrence Matrix (SCM). According to this study, SCM is the best to extract the most discriminant structural information concerning stroke subtype without parameters. These authors used 300 CT scans images (100 are normal, 100 are hemorrhagic stroke, and 100 are ischemic) that were obtained from a tomograph model GE Medical HiSpeed System (GEMSH). The SCM in the frequency domain presented high accuracy i.e. 98% in stroke classification. The study [60] aimed to extract the image features by analyzing CT scans brain tissue densities and used those features for stroke classification. Optimum Path Forest (OPF) classifier with Analysis of Brain Tissue Density (ABTD) feature selection algorithm got 99.30% of accuracy. Like earlier research, [68] worked on perfusion imaging and developed ANN model for identification of CT perfusion deficits with accuracy 85.8%. The CNN was used for anatomy segmentation of the brain lesions. Moreover, [28] studied raw perfusion MRI images to predict the final lesion in acute ischemic stroke using simple SVM technique and it demonstrated 95% accuracy. Since feature vectors size was quite large, in order to overcome dimensional problem, PCA was used and it preserved only the first principal vectors which allowed to explain 90% of total variance, contained in the training set. To access the generalizability of the classifier, K-fold cross-validation technique was implemented. Classifier SVM worked optimal because data points of binary classes are linearly separable. Ischaemic lesion segmentation is used to measure the damaged brain area(s); nonetheless, this procedure is time-consuming and less accurate when done manually. Study [39] presented deep supervised Fully Convolutional Network (FCN) to segment lesion using multimodal MRI imaging datasets with 70% accuracy.

Each dataset contained four modalities, namely T1, T2, DWI, and FLAIR. Intracerebral hemorrhage (ICH) is another one of the causes for high mortality rate therefore, [49] focused on multivariate analysis to predict hematoma expansion in spontaneous ICH with routinely available information using SVM and it scored 83.3% accuracy. Besides, randomized 179 search strategy was implemented for parameter tuning and recursive feature 180 elimination was used for feature selection in this study. Another important aspect is concerned with patient selection for thrombolytic procedures. In this regard, [5] CNN and ANN techniques were used for the prediction of functional thrombolysis outcomes in order to improve clinical decision making. Accuracy by CNN+ANN was 74% for the prediction of ‘mRS90’ (modified Rankin Scale (mRs) 0-1 in 90 days) and for ‘NIHSS24’ (National Institutes of Health Stroke Scale of greater than equals to 4 points in 24 hours) scored 71% accuracy.

Cerebral stroke is also caught an attention as a global health problem and if this could predict or classify automatically then that actually contributes to clinical

| 16     | Propose novel approach to extract CT scan image features based on human brain tissue densities and classify stroke (healthy brain or ischemic or hemorrhagic) | [60]      | For feature extraction: Analysis of Brain Tissue Density (ABTD) For classification: MLP, SVM, kNN, OPF and Bayesian | 420        | CT images                                     | ABTD with OPF: ACC= 99.30% | Early and more efficient stroke detection and diagnosis. |

(Continued)
Therefore, a step was taken by [50] and developed a ML model for stroke prediction using a hybrid ML approach on complete and imbalanced medical dataset. The RF was used for data imputation and automated hyperparameter optimization (AutoHPO) which is based on deep neural network (DNN) applied for stroke prediction. It obtained 71.6% accuracy and 67.4% sensitivity using 43,400 physiological data points. Another efforts were made by [21] for classification of stroke types (healthy brain, an ischemic or a hemorrhagic stroke) from 420 CT scans images by employing Convolutional Neural Networks (CNN) with 100% accuracy. The posturography is a well-known technique to measure the postural control and this was investigated by [29] using time series of data of 38 center of pressure displacements (19 are post stroke adults and 19 are healthy). Findings of the paper were for fractal features 77.6% accuracy, for entropy features 68.4%, and for both features 76.3% accuracy. Likewise, joint disorders happen in hemiparetic patient after a stroke. Study [43] was investigated automated movement detection using SVM classification technique and kinematic sensors data. Total 7 patients walked in different conditions such as stair descent, stair ascent, level ground, downslope, and upslope. The SVM improved accuracy up to 97.5% and it performed superior than ANN and radial basis function neural networks (RBF). Manual classification of stroke sub types is not an easy task thus, to automatize the process of sub typing ischemic stroke, [25] used several advanced ML techniques with NLP of over 1,091 of EHR text records for the classification of TOAST (sub types of ischemic stroke) sub types. Finally, the authors compared the performance of classical stroke prediction models with the proposed ML model for stroke prediction using a Hybrid ML approach on complete and imbalanced medical dataset. The RF was used for data imputation and imbalanced medical dataset. Table 4 (Continued).

(FFT) from atherosclerotic plaque is significant and difficult therefore, [67] employed LR on CT angiography and identified 5 quantitative shape descriptors of carotid FFT. Atrial fibrillation is another clinical issue which can lead to stroke or heart-related complications. Hence, the research [4] was done on the identification of the patient with atrial fibrillation during sinus rhythm using CNN (83.3% accuracy, 45.4% F1 score) and 1,80,922 electrocardiograph data points. Spatial neglect neglect is a common post-stroke sequela, which leads to asymmetric functional actions. Such patient normally has asymmetric functional actions. Multivariate pattern analysis classifier [7] classified disability-relevant spatial neglect based on 18 motor-attention network and connectivity data of stroke patients with 0.85 sensitivity and 0.72 specificity. In United Kingdom, stroke is one of the three highest mortality causes so [19] the RF, classification and regression tree, adaBoost techniques are applied on 45,613 UK primary care data points to explore potential under recording of post stroke spasticity.

**Stroke Treatment**

Table 6 follows the same structure like other tables mentioned in the Section 4.2 however, only 4 studies were found under this category. Several classification techniques were applied to modify the real-time display of virtual reality system to monitor a particular state of the patients based on their physiological reactions [6]. However, SVM with RBF achieved 91.43% of accuracy, shown in the Table 6. Improving the functional movements of the arm after stroke is significant part of stroke treatment, basically research idea [13] is to capture the linear acceleration and angular velocity of patient’s Upper Extremity (UE) using sensor positioned on patient’s wrists and this data is correctly classified with an average accuracy 94.80% in controls and 88.38% in stroke.

Moreover, [46] focuses to maintain and enhance the stroke patient’s engagement at time of stroke rehabilitation practicals. The classifiers ANN and Naive Bayes (NB) were able to learn the association between the actual engagement and applied stimulation on 500 data points of Electromyography (EMG), Electroencephalography (EEG), eye movements and facial expression. Remote quantitative Fugl-Meyer Assessment (FMA) is proposed framework for the stroke patients by [71] which is in the clinical and home settings. Ensemble Machine Learning (ELM) was employed to learn the relation between the 2 accelerometer and 7 flex sensors data to clinical FMA scores.

**Stroke Prognostication**

Last but not least is stroke prognostication. Table 7 presents 9 studies on stroke diagnosis and its structure explained in the Section 4.2. Thrombolysis is a treatment to diffuse wild clots in blood vessels and improves flow of blood although, devastating complication in such

| 3      | Present a novel scoring system for predicting functional outcome after ICH at 3 and 12 months follow-up | [32]      | RF for feature selection, LR | 575     | intracerebral Hemorrhage Outcomes             | for predicting functional status: AUC= 0.89 (3 months) AUC= 0.87 (12 months) | Comprehensive prediction and higher discrimination of functional outcomes in patients with ICH. |
| 4      | Predict good reperfusion after endovascular treatment (EVT) and good functional outcome | [35]      | ResNet with RFNN  | 1,301   | CT angiography images.                        | AUC= 0.71       | Enhanced functional outcome prediction after acute ischemic stroke can potentially improve treatment selection (e.g., to only consider patients with a good response to endovascular treatment). |
| 5      | Predict speech production skills in stroke patients.                      | [36]      | GPR               | 270     | cross-sectional, longitudinal patient data   | $R^2 = 0.84$    | Realistic long-term behavioral outcome predictions after stroke (e.g., severity of speech production impairments) with the purpose of answering stroke patients’ expectations, i.e., when and to what extent they should expect to improve. |
| 6      | Predict activities of daily living (Barthel index as the indicator) is crucial for post-stroke patients. | [48]      | LR, SVM, RF       | 313     | assessments                                   | for BI status:LR and RF AUC= 0.79 for BI score: SVM, MAE= 9.86 LR, MAE= 9.95 | Realistic goal setting and development of a specific and individual discharge plan due to the accurate prediction of |
treatment is Symptomatic intracranial hemorrhage (SICH) can lead to mortality. The SVM was used for the prediction of SICH using CT scan images of 116 acute ischaemic stroke patients and has obtained 0.744 AUC. The performance of the SVM was compared with SEDAN and HAT scores (prognostication tools). Similarly, RF was employed [32] to identify factors or feature selection from 575 intracerebral hemorrhage (ICH) outcomes and developed LR model for prognosticating functional status (mRS score, 0 to 3 is good and mRS score, 4 to 6 is poor) based on these factors. LR model reported 0.89 AUC for 3 months and 0.87 for 12 months. Generated results were then compared with ICH score. Brain arteriovenous malformation consists of a set of abnormal blood vessels in the brain. Research [3] focused on identification of outcome which influences outcome in the brain. Two approaches ANN and SVM were employed on 199 demographics and clinical data points and recorded 97.5% accuracy. Moreover, DL approach, structured receptive field neural networks-residual neural network was applied on 1,301 CT angiography images for predicting outcomes of acute ischemic stroke patients [35], reported AUC = 0.71. It got higher accuracy than radiological image biomarkers for outcome prediction.

Besides, MRI images were used to extract lesion information which were injected to Gaussian process model regression [36] for the prediction of behavioural outcomes and recovery of speech production after stroke. The LR, SVM, and RF techniques were applied on 15 rehabilitation assessments from 313 individuals for the prediction of Barthel Index (BI) status and score at discharge of post-stroke patients. Specifically, LR, SVM, and RF were used for BI status and SVM and LR used for BI scores. Stroke topography has widely been mapped with functional outcome using manual lesion segmentation. Therefore, proposed [54] powerful ML based technique (SVM) that improved median accuracy (82.8%) using 297 stroke images as well as provided an important insight on critical brain areas for long-term functional outcome (good or poor). Similarly, linear SVM employed [65] on functional and clinical data of 55 individuals. The authors investigated the exact role of common inflammatory biomarkers in the prediction of motor and cognitive improvement after rehabilitation in the early stages of stroke. Eventually, improved ML or DL based predictions of stroke outcome enhance clinical efficacy. Gaussian Process Regression [62] was used to decode post-stroke motor function from 50 structural brain images of chronic stroke patients and results are showed in the Table 7.

**Table 7 (Continued)**

| Sr. No | Objective | ML-based approach | Reference | Samples | Features | Clinical Implications |
|--------|-----------|-------------------|-----------|---------|----------|----------------------|
| 7      | Classify patients into good vs. poor functional outcome | SVM       | [54]     | 297     | MRI images | Based on different masks to limit subsets of voxels: R = 0.83, RMSE = 0.68 | Enhanced prediction of long-term motor outcomes following stroke. Greater understanding of the dynamics of inflammatory biomarkers due to the implementation of innovative treatments. |
| 8      | Predict post-stroke long-term upper limb motor function that can contribute to improve clinical efficacy | GPR       | [62]     | 50      | functional and clinical data | | |
| 9      | Predict motor and cognitive improvement for rehabilitation in the early stage of stroke | linear SVM | [65]     | 55      | linear SVM | | |
employed different performance metrics for different tasks, considering different datasets, techniques, and tuning parameters. Hence, we only mention the research areas which were targeted in more than one study and the studies which report highest classification accuracy in each section. The stroke prevention category contains 2 studies on carotid-artery atherosclerosis and the stroke diagnosis category consists of 5 studies on classification of stroke types. We identified that 4 out of 39 studies are focused on regression. Hence, the current review has more articles on classification, we present classification accuracy of an optimal model from each category. For example, [60] has achieved the highest 99.30% accuracy in stroke diagnosis. For stroke prevention, [21] mentioned 100% accuracy for classification of ischemic stroke subtypes. If we see the results in stroke treatment category, [6] got optimal result, accuracy 91.43% and in prognostication, [3] received 97.5% accuracy. Figure 2 signifies 3 layers, consists of stroke category, dataset and outer layer represents optimal model of particular study. Here, we try to visualize 39 studies in one figure to get some valuable insights or conclusions.

1. After reviewing all studies, we found 4 main categories of stroke problem such as prevention, diagnosis, treatment and prognostication, mentioned in the first ring of the Figure 2.

2. The second ring comprises names of the dataset of each category. It shows 7 studies from CT images under stroke diagnosis, 2 from prognostication category, and 1 from prevention. After that, MRI images are used in 5 studies, each 2 from diagnosis and prognostication, 1 from prevention, 2 times sensor data and ultrasound images. ML powered by DL for the task of image processing, has emerged rapidly in recent years. Consequently, CT scan image is the most frequently used data in a stroke field.

3. Finally, the third ring presents an optimal model of each study. 10 studies appeared with SVM as optimal model, then RF (6 times), LR (4 times), ANN and CNN (each 3 times) from 4 categories. Thus, SVM is a

![Fig. 2. Multi-level pie chart of ML approaches and types of data used for stroke prevention, stroke diagnosis, treatment, and prognostication.](image-url)
commonly used technique as well as highly efficient to map a data in a stroke field.
4. SVM and RF are applied and obtained as an optimal models in at least 1 study from each category.
5. Since 18 studies are found in the stroke diagnosis category, the rest of the categories require to implement more research ideas. Specifically in stroke treatment.
6. In this review, the majority of research problems are classification and only 4 studies are related to regression. It seems general nature of problem in stroke field is classification.

This review was intended to showcase ML approaches employed on various datasets used for solving various stroke problems for better healthcare system as well as further investigation. We believe that it allows a better understanding and valuable insights into the effectiveness of ML-based stroke problems in enhancing medical practices.
