Ethnic disparities in preventable hospitalisation in England: an analysis of 916 375 emergency admissions

Jakob Petersen,1 Jens Kandt,2 Paul Longley1

ABSTRACT

Objectives To study ethnic inequalities in ambulatory care sensitive conditions (ACSC) in England.

Design Observational study of inpatient hospital admission database enhanced with ethnicity coding of patient surnames. The primary diagnosis of the first episode in spells with emergency admission were coded with definitions for acute ACSC, chronic ACSC and vaccine-preventable diseases.

Setting National Health Service England.

Participants 916 375 ACSC emergency admissions in 7 396 184 patients were identified between April 2011 and March 2012.

Main outcome measures ORs of ACSC for each ethnic group relative to the White British majority group adjusted for age, sex and area deprivation.

Results Acute ACSC admission risk adjusted for age and sex was particularly high among Other (OR 1.73; 95% CI 1.69 to 1.77) and Pakistani (1.51; 95% CI 1.48 to 1.54) compared with White British patients. For chronic ACSC, high risk was found among Other (2.02; 95% CI 1.97 to 2.08), Pakistani (2.07; 95% CI 2.02 to 2.12) and Bangladeshi (1.36; 95% CI 1.30 to 1.42). For vaccine-preventable diseases, other (2.42; 95% CI 2.31 to 2.54), Pakistani (1.94; 95% CI 1.85 to 2.04), Bangladeshi (1.48; 95% CI 1.36 to 1.62), Black African (1.45; 95% CI 1.36 to 1.54) and white other (1.38; 95% CI 1.33 to 1.43) groups. Elevated risk was only partly explained in analyses also adjusting for area deprivation.

Conclusions ACSC admission was especially high among individuals of Bangladeshi, Pakistani, Black African, white other or other background with up to twofold differences compared with the white British group. This suggests that these ethnic groups are not receiving optimal primary care.

INTRODUCTION

Emergency hospital admissions are distressing for patients, associated with poorer long-term outcomes and are costly to the healthcare system. Many healthcare systems are undergoing reforms to reduce emergency admissions by improving early detection, treatment and monitoring of a range of conditions that could be treated or prevented in less intensive settings, that is, primary and community care services.1 2 These conditions are known as ambulatory care sensitive conditions (ACSCs). ACSCs include acute, chronic and vaccine-preventable conditions such as urinary tract infections, chronic obstructive pulmonary disease (COPD) and pneumonia. ACSC admissions have been associated with patients under the age 5 years, the elderly, deprivation and ethnicity.3

The English National Health Service (NHS) saw a 40% rise in ACSC admissions between 2001 and 20114 and a 42% rise in emergency admissions between 2006 and 2017 making this a policy area of urgency.5 ACSC indicators were introduced into the NHS Commissioning Outcome Framework in 2012 to monitor this area for quality of care improvements for the general population.6 While ACSC has been studied before in England, there has to our knowledge not been a study of ethnic inequalities in ACSC in England nor of its geographical distribution for these groups. A study of ACSC is particularly pertinent for the understanding of ethnic inequalities, because they are indicative of how patients from different minorities access and navigate the healthcare system. Studies in USA, New Zealand and Scotland have found higher risk of ACSC admission for many ethnic minorities compared with the white majority populations.7–9 A recent Scottish study found that South Asian groups had higher risk of ACSC admission compared with the white majority group.4

The primary objective of this study was to elucidate whether ethnicity plays an important role in ACSC among emergency admissions in England at a national and regional level. For this study, we gathered data on hospital admission from Hospital Episode Statistics (HES) for different ethnic groups in 2011 and linked them to the 2011 Census population estimates.

The completeness of ethnicity data in HES was very low in the 1990s, but has since improved.7 To address potential gaps in the ethnicity records, a freely available software, Ethnicity Estimator (EE) was used to code patient surnames to major ethnic groups.10 We report on the EE as a secondary objective of this paper.

METHODS

Inpatient hospital admission records with an emergency admission route were obtained from NHS England’s HES, April 2011–March 2012. Diagnoses in HES are coded to the Tenth Revision of the International Classification of Diseases system.11 The primary diagnosis of the first episode in spells with emergency admission were coded with definitions for acute ACSC, chronic ACSC and vaccine-preventable diseases5 (online supplemental table S1), for definitions). Only the first episode for each admission was considered to focus on whether the
admission could have been prevented. The data were deduplicated so that a patient could only contribute to the risk of each ACSC group once.

In this population-based study, the denominators came from the 2011 Census and the numerators from HES. The census ethnicity classification is the result of extensive consultation and HES ethnicity classification was based on the 2001 Census. We made a few modifications to harmonise the differences between how data are collected and released at small area level and the composition of company boards. Building on Onomap, the maps of ACSC emergency admissions in 739,618 patients were identified in 2011/12. The most common ACSCs were urinary tract infections (17.0% of all ACSC), COPD (12.5%), and pneumonia (10.5%) (table 1). The majority of ACSC patients were from the white British group (83.3%), followed by white other (3.7%), Pakistani (2.5%), other (2.2%), Indian (2.0%), Black African (1.1%), Asian other (1.1%), White Irish (1.1%), mixed (1.0%), Black Caribbean (0.9%), Bangladeshi (0.6%) and Chinese (0.2%) (table 2). Among all patients, especially those from other and Pakistani groups had a significantly higher risk of emergency admission for preventable causes with some variation between gender and whether acute ACSC, chronic ACSC or vaccine-preventable diseases.

Age-standardised and sex-standardised ORs of acute ACSC admissions were particularly high for other (OR 1.73; 95% CI 1.69 to 1.77) and Pakistani (1.51; 95% CI 1.48 to 1.54) patients (figure 1). For chronic ACSC, the ORs were very high for other (2.02; 95% CI 1.97 to 2.07), Pakistani (2.07; 95% CI 2.02 to 2.11), and Bangladeshi (1.36; 95% CI 1.30 to 1.42) groups. For vaccine-preventable diseases, the same was true for other (2.42; 95% CI 2.31 to 2.54), Pakistani (1.94; 95% CI 1.85 to 2.04), Bangladeshi (1.48; 95% CI 1.36 to 1.62), Black African (1.45; 95% CI 1.36 to 1.54) and white other (1.38; 1.33 to 1.43) groups. For the combined ACSC outcome, two groups had particularly elevated ORs, Pakistani (1.74; 95% CI 1.71 to 1.76) and other (1.92; 95% CI 1.88 to 1.95) (table 3). Standardising the incidence for area deprivation showed that the results for the groups with elevated risk was partly, but not entirely explained by area deprivation (figure 1, table 3). Similar findings were obtained when analysing the data without surname imputation (online supplemental figure S1 and table S2). Overall, Chinese, mixed and white Irish had risks well below White British and some groups had comparable risks. Especially, the Pakistani and other groups appear to be faced with problems around health-care access for acute and chronic preventable conditions. The results on vaccine-preventable diseases suggest that many ethnic minorities are less well protected.

The maps of ACSC SMR showed higher risk in Inner London and the old industrial areas of the Midlands and the North (figure 2). This was consistent for both White British and

### Table 1  Emergency admissions for ambulatory care sensitive conditions in 2011

| Conditions                      | Freq. | %     |
|---------------------------------|-------|-------|
| Acute ACSC                      |       |       |
| Cellulitis                      | 63044 | 6.9   |

ACSC, ambulatory care sensitive conditions; COPD, chronic obstructive pulmonary disease; ENT, ear, nose, and throat; TB, tuberculosis; UTI, urinary tract infection.

Petersen I, et al. J Epidemiol Community Health 2022;76:85–91. doi:10.1136/jech-2020-216005
Pakistanis, although Pakistani patients experienced higher risk in other parts of the country.

The sensitivity of the EE software to correctly predict the HES-recorded ethnicity varied by ethnic group, for example, >90% for white British and <10% for black Caribbean (table 2).

**DISCUSSION**

Ethnic inequalities in health are manifest in numerous ways and predominantly have adverse social determinants such as poor living and working conditions, discrimination, social exclusion, adverse health behaviours and poor healthcare accessibility.\(^\text{19}\) The incidence of preventable hospitalisations indicates how patients from ethnic minorities access and navigate the healthcare system. We found that among all emergency admissions, especially patients with Other, Bangladeshi, Pakistani, Black African and white other backgrounds had higher OR of emergency ACSC relative to the white majority group,\(^\text{6}\) Common for these studies are calls to improve not only access to primary care but also the quality of care received for both ethnic and migrant groups.

The admission risk was generally lower for Chinese patients compared with white British. The Chinese group in the UK has been associated with fewer health problems than other groups including lower mortality.\(^\text{20}\)

The results of this study suggest that many ethnic groups are not receiving optimal primary care in terms of either access or quality. A recent review of ethnic inequalities in the UK reported persistent inequalities in health outcomes.\(^\text{19}\) While several policies aim to deliver equal access to healthcare, ethnic minorities are generally less satisfied with the care they receive than the white British population. The COVID-19 pandemic has renewed concerns that ethnic minorities are more likely to be infected and diagnosed with severe outcomes including death.\(^\text{21}\)

Specifically, South Asian groups have been particularly hard hit in the second wave of the UK epidemic. Previous experience indicates that ethnic minorities are less likely to be vaccinated for a range of diseases and there are early indications that some ethnic groups might be more hesitant about getting vaccinated against COVID-19.\(^\text{22}\) This is also consistent with the findings of this study in terms of higher risk of emergency admission for vaccine-preventable diseases. ACSC indicators were introduced into the NHS Commissioning Outcome Framework in 2012.\(^\text{1}\) They are not direct indicators of healthcare delivery but are deemed to have value in the monitoring quality of care at a high level. Further studies would therefore be required to map out the more specific healthcare needs and healthcare accessibility for vulnerable groups. It will be important to identify health system factors as well as patient factors, for example, studying whether more can be done to increase access and quality of care.

EE, ethnicity estimator; NHS, National Health Service.
Figure 1  ORs of ACSC admission by ethnic group relative to white British adjusted for age, sex and area deprivation, 2011. Top: acute ACSC. Middle: chronic ACSC. Bottom: vaccine-preventable diseases. Open circles: risk adjusted for age group and sex. Filled circles: adjusted for age group, sex and area deprivation. ACSC, ambulatory care sensitive conditions.
The maps showed regional effects in the incidence of preventable hospitalisation. Inner London and the old industrial centres of the Midlands and the North had higher incidence than the national average. These industrial and postindustrial areas are associated with persistent deprivation on multiple accounts and an indication that preventable hospitalisation overlap with regional patterns of deprivation. The incidence for the Pakistani group was more widespread than for the White British and not only concentrated in the most deprived regions. The elevated risk of ACSC admission attenuated partly when adjusting for area deprivation, which again suggests that the difference between these groups and white British was only partly explained by residence in deprived areas.

The other ethnic group was associated with the highest risk of ACSC admissions. This is inherently not a well-defined group, which makes the interpretation of the results more complicated. It could highlight problems associated with a conglomerate of marginalised ethnic groups, but more detailed studies would be needed to unpack this.

**LIMITATIONS**

HES is a unique data set with both strengths and limitations. It is an administrative dataset that may also reflect time-variant healthcare system factors, for example, as a result of policy-driven target setting. As a particular strength, HES captures all hospital admissions commissioned by NHS England, which is estimated to cover 98%–99% of all hospital activity in England. Patients have recently gained the right to opt out of having their data used for research retrospectively. So far only a small proportion of HES patients have exercised this right. For our research, we rely on the accuracy of the coding of each episode of care and acknowledge that while the accuracy may vary, studies have found HES adequate for both research and managerial decision making.

| White other  | 1.20 (1.18 to 1.21)          | <0.001  | 1.16 (1.15 to 1.18)                                  | <0.001  |
| White Irish  | 0.88 (0.86 to 0.90)          | <0.001  | 0.85 (0.83 to 0.87)                                  | <0.001  |
| Mixed        | 0.60 (0.59 to 0.61)          | <0.001  | 0.57 (0.56 to 0.59)                                  | <0.001  |

NHS-recorded ethnicity replaced with EE prediction where missing (Kandt and Longley, 2018). ACSC, ambulatory care sensitive conditions; EE, ethnicity estimator; NHS, National Health Service.

---

**Figure 2** Preventable hospitalisation SMR by local authority district for white British and Pakistani in 2011. SMR, standardised morbidity ratio.
Definitions for ACSC vary in the literature in the number of conditions that are included. We have aligned our definitions with those published by Bardsley et al., which are also used by the English NHS.

Recording of ethnicity will never be entirely objective as it relates to identity and data in this study were furthermore derived from two different sources of self-reported ethnicity, i.e. HES for admissions and Census 2011 for base population. It cannot be excluded from consideration that recorded ethnicity may vary with the timing, mode, and context of the response process. Moreover, the ethnicity data in HES is deemed to be self-reported, but in practice there will likely be instances in which it is staff-reported.

Recorded ethnicity information in HES was below 50% before 2000, but has since improved. Only 3.2% of patients in this 2011 study had missing ethnicity information. Combining HES-recorded ethnicity with surname derived EE, as in this study, will also not escape a degree of subjectivity, but is a way to develop a more complete analysis that avoids imputing as missing-at-random. While the imputation increased the incidence for these groups in absolute terms, it only had a modest effect on relative risk and did not change the main findings of the study (figure 1, table 3, online supplemental figure S1 and table S2). Many bearers of Irish surnames today perceive themselves as White British. Surname imputation is more error prone as a consequence. Similar results were nonetheless obtained with and without surname imputation for this group too.

Mixed ethnic group could not be enhanced in the analyses as there is no category for it in the current version of the EE software. About 2% of the population identified as mixed ethnicity in the 2011 Census.

The deprivation adjustment of the regression analyses was conducted at the level of local authorities because of data availability. It is possible that more of the variation could have been explained if it had been possible to adjust at a finer level of geography.

**CONCLUSIONS**

Preventable emergency admissions were especially high among patients with Bangladeshi, Pakistani, black African, white other or other background with up to twofold differences compared with the white British majority group. Further studies will be needed to uncover specific barriers. Greater vigilance among health staff along with outreach activities to increase uptake of health checks and other interventions could potentially increase early detection of chronic conditions in these groups. Problems with acute conditions suggest underuse of general practices and community services. For vaccine-preventable diseases, ethnic disparities suggest that the offer of vaccinations in high-risk groups such as the elderly does not reach all ethnic groups equally well. There was some geographical overlap for the combined ACSC endpoint with regions of high levels of deprivation, but the geographical distribution was more dispersed for the Pakistani compared with the white British group. The inequalities in ACSC revealed in this study suggest that several ethnic minorities are not receiving optimal primary and preventive care.

**Contributors** All authors contributed to the planning and reporting of this work and the responses to reviewers (JP, JK and PL). JP conducted the analysis of the data. JK designed and arranged the ethnicity coding of HES records. The corresponding author attests that all listed authors meet the authorship criteria and that no others meeting the criteria have been omitted.

**Funding** The UK Economic and Social Research Council is acknowledged for its support for the UCL Consumer Data Research Centre (CDRC) enabling this research (Grant ES/L011840/1).

**Disclaimer** The funder had no direct role in relation to the specific study.

**Map disclaimer** The depiction of boundaries on this map does not imply the expression of any opinion whatsoever on the part of BMJ (or any member of its editorial staff) concerning the legal status of any country, territory, jurisdiction or area or any of its authorities. This map is provided without any warranty of any kind, either express or implied.

**Competing interests** None declared.

**Patient consent for publication** Not required.

**Ethics approval** Ethical approval was obtained from Bromley REC (Reference: 13/LO/1355) for analyses of patient-level HES data. The HES data licence reference is DARS-NIC-28051-Q3K7L.

**Provenance and peer review** Not commissioned; externally peer reviewed.

**Data availability statement** Data may be obtained from a third party and are not publicly available. The data that support the findings of this study are available from NHS Digital, but restrictions apply to the availability of these data, which were used under license for the current study, and so are not publicly available.

**Supplemental material** This content has been supplied by the author(s). It has not been vetted by BMI Publishing Group Limited (BMJ) and may not have been peer-reviewed.
