Abstract. The segment number of a planar graph is the smallest number of line segments whose union represents a crossing-free straight-line drawing of the given graph in the plane. The segment number is a measure for the visual complexity of a drawing; it has been studied extensively.

In this paper, we study three variants of the segment number: for planar graphs, we consider crossing-free polyline drawings in 2D; for arbitrary graphs, we consider crossing-free straight-line drawings in 3D and straight-line drawings with crossings in 2D. We establish lower and upper bounds on the new variants of the segment number, mostly for cubic graphs, depending on the connectivity of the given graph. We also construct an infinite family of planar graphs where the classical segment number is asymptotically twice as large as each of the new variants of the segment number.

1 Introduction

When drawing a graph, a way to keep the visual complexity low is to use few geometric objects for drawing the edges. This idea is captured by the segment number of a (planar) graph, that is, the smallest number of crossing-free line segments that together constitute a straight-line drawing of the given graph.

The arc number of a graph is defined analogously with respect to circular-arc drawings. So far, both numbers have only been studied for planar graphs. Two obvious lower bounds for the segment number are known \cite{dujmovic2011segment}: (i) $\eta(G)/2$, where $\eta(G)$ is the number of odd-degree vertices of $G$, and (ii) the planar slope number of $G$, that is, the smallest number $k$ such that $G$ admits a crossing-free straight-line drawing whose edges have $k$ different slopes.

Dujmović et al. \cite{dujmovic2011segment}, who introduced segment number and planar slope number, showed among others that trees can be drawn without crossings such that the optimum segment number and the optimum planar slope number are achieved simultaneously. In fact, any tree $T$ admits a drawing with $\eta(T)/2$ segments and

\textsuperscript{*} A.W. acknowledges support from DFG grant WO758/9-1.
$\Delta(T)/2$ slopes, where $\Delta(T)$ is the maximum degree of $T$. Unfortunately, these drawings need exponential area. Therefore, Schulz [18] suggested to study the arc number of planar graphs. Among other things he showed that any $n$-vertex tree can be drawn on a polynomial-size grid $(O(n^{1.81}) \times n)$ using at most $3n/4$ arcs.

Another measure for the visual complexity of a drawing of a graph is the minimum number of lines whose union contains a straight-line crossing-free drawing of the given graph. This parameter is called the line cover number of a graph $G$ and denoted by $\rho_1^2(G)$ for 2D (where $G$ must be planar) and $\rho_1^3(G)$ for 3D. Together with the plane cover number $\rho_2^3(G)$ and other variants, these parameters have been introduced by Chaplick et al. [2]. They also showed that both line cover numbers are $\exists \mathbb{R}$-hard to compute [3]. (For background on $\exists \mathbb{R}$, see Schaefer’s work [17].)

Upper bounds for the segment number and the arc number (in terms of the number of vertices, $n$, ignoring constant additive terms) are known for series-parallel graphs ($3n/2$ vs. $n$), planar 3-trees ($2n$ vs. $11n/6$), and triconnected planar graphs ($5n/2$ vs. $2n$) [5,18]. The upper bound on the segment number for triconnected planar graphs has been improved for the special cases of triangulations and 4-connected triangulations (from $5n/2$ to $7n/3$ and $9n/4$, respectively) by Durocher and Mondal [6]. Hültenschmidt et al. [10] provided bounds for segment and arc number under the additional constraint that vertices must lie on a polynomial-size grid. They also showed that $n$-vertex triangulations can be drawn with at most $5n/3$ arcs, which is better than the lower bound of $2n$ for the segment number on this class of graphs. For 4-connected triangulations, they need at most $3n/2$ arcs. Kindermann et al. [12] recently strengthened some of these results by showing that many classes of planar graphs admit nontrivial bounds on the segment number even when restricting vertices to a grid of size $O(n) \times O(n^2)$. For drawing $n$-vertex trees with at most $3n/4$ segments, they reduced the grid size to $n \times n$. Among other things Durocher et al. [7] showed that the segment number is NP-hard to compute with respect to a fixed embedding, even in the special case of arrangement graphs. They also showed that the following partial representation extension problem is NP-hard: given an outerplanar graph $G$, an integer $k$, and a straight-line drawing $\delta$ of a subgraph of $G$, is there a $k$-segment drawing that contains $\delta$? It is still open, however, whether the segment number is fixed-parameter tractable.

In this paper, we consider several variants of the planar segment number $\operatorname{seg}_2$ that has been studied extensively. In particular, we study the 3D segment number $\operatorname{seg}_3$, which is the most obvious generalization of the planar segment number. It is the smallest number of straight-line segments needed for a crossing-free straight-line drawing of a given graph in 3D. We also study the crossing segment number $\operatorname{seg}_c$ in 3D, where edges are allowed to cross, but they are not allowed to overlap or to contain vertices in their interiors. In this case, by Lemma 1, the minimum number of segments constituting a drawing of a given graph can be achieved by a plane drawing. Finally, for planar graphs, we study the bend segment number
Table 1: Overview over existing and new bounds on variants of the segment number of cubic graphs. The upper bounds hold for all \(n\)-vertex graphs of a certain vertex connectivity \(\gamma\). The lower bounds are existential; there exist graphs for which they hold. Note that \(\text{seg}_2\) and \(\text{seg}_\infty\) are defined only for planar graphs. We skip more specialized known results (e.g., concerning grid size [10] or triangulations [6]).

| \(\gamma\) | \(\text{seg}_2(G)\) | \(\text{seg}_3(G)\) | \(\text{seg}_\infty(G)\) | \(\text{seg}_\angle(G)\) |
|---|---|---|---|---|
| 1 | \(\geq 5n/6\) [Prp. 2] | \(\geq 5n/6\) [Prp. 2] | \(\geq 5n/6\) [Prp. 2] | \(\geq 5n/6\) [Prp. 2] |
| 2 | \(\geq 3n/4\) [Prp. 1] | \(\geq 5n/6\) [Prp. 2] | \(\geq 3n/4\) [Prp. 1] | \(\geq 3n/4\) [Prp. 1] |
| 3 | \(= n/2 + 3\) [11, 15] | \(\leq n + 2\) [Th. 2] | \(\leq n + 2\) [Th. 2] | \(\geq 7n/10\) [Prp. 5] |
| | | | | \(\text{seg}_\angle \equiv \text{seg}_2\) |

\(\text{seg}_\angle\) in 2D, which is the smallest number of straight-line segments needed for a crossing-free polyline drawing of a given graph in 2D.

Durocher et al. [7] were also interested in the 3D segment number. They stated that their proof of the NP-hardness of the above-mentioned partial representation problem can be adjusted to 3D. They suspected that the 3D segment number remains NP-hard to compute even if the given graph is subcubic. Instead, they showed that a variant of the 3D segment number is NP-hard where one is given a 3D drawing and additional co-planarity constraints that must be fulfilled in the final drawing.

**Our Contribution.** First, we establish some relationships between the variants of the segment number; see Section 2. Then we turn to the complexity of computing the new variants of the segment number; see Section 3. By re-using ideas from the \(\exists R\)-hardness proof of Chaplick et al. [3] regarding the computation of the line cover numbers \(\rho_2^2\) and \(\rho_3^2\), we establish the \(\exists R\)-hardness (and hence the NP-hardness) of the old and all new variants of the segment number; \(\text{seg}_2\), \(\text{seg}_3\), \(\text{seg}_\infty\), and \(\text{seg}_\angle\). The hardness holds even for the restricted class of arrangement graphs, which we define in Section 2 and which have vertex degrees in \(\{2, 3, 4\}\). Thus, we nearly answer the open problem of Durocher et al. [7] concerning the computational complexity of the 3D segment number for subcubic graphs.

Our main contribution consists in algorithms and lower-bound constructions for connected (\(\gamma = 1\)), biconnected (\(\gamma = 2\)), and triconnected (\(\gamma = 3\)) cubic graphs; see Table 1. To put these results into perspective, note that any cubic graph with \(n\) vertices needs at least \(n/2\) and at most \(3n/2\) segments to be drawn, regardless of the drawing style. (In contrast, every connected cubic graph can be drawn using only four slopes [16]). We prove our bounds in Section 4. Note that for cubic graphs, vertex- and edge-connectivity are the same [4, Thm. 2.17].

We introduce two pieces of notation before we start. To avoid confusion between the variants of the segment number, from now on we use \(\text{seg}_2\) for the classical planar segment number. For a given polyline drawing \(\delta\) of a graph in 2D or 3D, we denote by \(\text{seg}(\delta)\) the number of (inclusionwise maximal) straight-line segments of which the drawing \(\delta\) consists.
Attaching a fan (thin edges) to a vertex of a triangulation (thick edges) of maximum degree 6

2 Relationships Between Segment Number Variants

Lemma 1. Given a graph $G$, for each straight-line drawing $\delta$ of $G$ where edges are allowed to cross, but not allowed to overlap or to contain vertices in their interiors exists a plane drawing $\delta'$ of $G$ with the above properties such that $\text{seg}(\delta') \leq \text{seg}(\delta')$.

Proof. For each triplet $u,v,w$ of three distinct vertices of $G$ in $\delta$, let $P(u,v,w)$ be the plane or line spanned by the vectors $\overrightarrow{uv}$ and $\overrightarrow{wv}$, and let $P$ be the set of all such planes or lines. Choose a point $A$ in $\mathbb{R}^3 \setminus \bigcup P$ that does not lie in the xy-plane. Let $\delta'$ be the drawing that results from projecting $\delta$ parallel to the vector $OA$ onto the xy-plane. Due to the choice of our projection, $\delta'$ may contain crossings, but no edge contains a vertex to which it is not incident, and no two edges overlap. By the construction, $\text{seg}(\delta') \leq \text{seg}(\delta)$. \qed

Corollary 1. For any graph $G$ it holds that $\text{seg}_{\times}(G) \leq \text{seg}_3(G)$.

Proposition 1. There is an infinite family of planar graphs $(S_i)_{i \geq 3}$ such that $S_i$ has $n_i = i^3 - i + 6$ vertices and the ratios $\text{seg}_2(S_i)/\text{seg}_3(S_i)$, $\text{seg}_2(S_i)/\text{seg}_{\times}(S_i)$, and $\text{seg}_2(S_i)/\text{seg}_{\times}(S_i)$ all converge to 2 with increasing $i$.

Proof. We construct, for $i \geq 3$, a triangulation $T_i$ with maximum degree 6 and $t_i = i^2 - 2i + 3$ vertices (and, hence, $3t_i - 6$ edges and $2t_i - 4$ faces), as follows. Take two triangular grids of side length $i - 1$ (a single triangle is a grid of side length 1) and glue their boundaries, identifying corresponding vertices and edges. Clearly, the result is a (planar) triangulation. Let $s_i = \text{seg}_2(T_i)$. Then, by the result of Dujmović et al. \cite{5}, $s_i \leq 5t_i/2$.

We assume that $i$ is even. To each vertex $v$ of the triangulation, we attach an $i$-fan, that is, a path of length $i$ each of whose vertices is connected to $v$. Let $S_i$ be the resulting graph, which has $n_i = t_i(i + 2)$ vertices.

In 2D, no matter how the triangulation is drawn, only three vertices lie on the outer face. Consider an $i$-fan incident to one of the $t_i - 3$ inner vertices; see Fig.\cite{1a} Each such $i$-fan must be placed into a triangular face and needs at least $i - 3$ segments that are disjoint from the drawing of the triangulation. (Here we
use that every vertex has degree at most 6.) Hence, \( \text{seg}_2(S_i) \geq (t_i - 3) \cdot (i - 3) = i^3 - O(i^2) \).

In 3D on the other hand, we can draw every fan in a plane different from the triangulation such that the fan’s path lies on three segments and the remaining edges are paired such that each pair shares a segment; see Fig. 1b. Hence, \( \text{seg}_3(S_i) \leq t_i \cdot (i/2 + 3) + s_i = i^3/2 + O(i^2) \). Due to Corollary 1, \( \text{seg}_x(S_i) \leq \text{seg}_3(S_i) \).

To bound \( \text{seg}_\angle(S_i) \), observe that we can modify the layout of the triangulation as in Fig. 1c such that every vertex is incident to an angle greater than \( \pi \) without any incoming edges. This can be achieved as follows. On each inner vertex \( v \), place a disk \( D_v \) whose radius is (slightly smaller than) the minimum over the lengths of the incident edges divided by 2 and over the distances to all non-incident edges. The resulting disks have positive radii and are pairwise disjoint. Now we go through all vertices. Let \( v \) be the current vertex and let \( \partial D_v \) be the boundary of \( D_v \). We bend all edges incident to \( v \) at \( \partial D_v \) and place \( v \) on some unused point on \( \partial D_v \). As a result, every vertex is incident to an angle greater than \( \pi \) without any incoming edges. In this area (marked red in Fig. 1c), we can place the corresponding fan. The modification introduces at most two bends in every edge of the triangulation. Hence, \( \text{seg}_\angle(S_i) \leq t_i \cdot (i/2 + 3) + 3 \cdot (3t_i - 6) = i^3/2 + O(i^2) \). \( \Box \)

**Open Problem 1** What are upper bounds for the ratios \( \text{seg}_2(G) / \text{seg}_3(G) \), \( \text{seg}_2(G) / \text{seg}_\angle(G) \), and \( \text{seg}_2(G) / \text{seg}_x(G) \) with \( G \) ranging over all planar graphs?

## 3 Computational Complexity

Chaplick et al. [8, Theorem 1] showed that it is \( \exists \mathbb{R} \)-hard to decide for a planar graph \( G \) and an integer \( k \) whether \( \rho_{\angle}^2(G) \leq k \) and whether \( \rho_{\angle}^3(G) \leq k \). We follow their approach to show the hardness of all variants of the segment number that we study in this paper.

A simple line arrangement is a set \( L \) of \( k \) lines in \( \mathbb{R}^2 \) such that each pair of lines has one intersection point and no three lines share a common point. We define the arrangement graph for a set of lines as follows [1]: The vertices correspond to the intersection points of lines and two vertices are adjacent in the graph if and only if they lie on the same line and no other vertex lies between them. The ARRANGEMENT GRAPH RECOGNITION problem is to decide whether a given graph is the arrangement graph of some set of lines.

Bose et al. [1] showed that this problem is NP-hard by reduction from a version of PSEULOLINE STRETCHABILITY for the Euclidean plane, whose NP-hardness was proved by Shor [19]. It turns out that ARRANGEMENT GRAPH RECOGNITION is actually an \( \exists \mathbb{R} \)-complete problem [8, page 212]. This stronger statement follows from the fact that the Euclidean PSEULOLINE STRETCHABILITY is \( \exists \mathbb{R} \)-hard as well as the original projective version [14,17].

**Theorem 1.** Given a planar graph \( G \) and an integer \( k \), it is \( \exists \mathbb{R} \)-hard to decide whether \( \text{seg}_2(G) \leq k \), whether \( \text{seg}_\angle(G) \leq k \), and whether \( \text{seg}_x(G) \leq k \).
Proof. Similarly to Chaplick et al. [3, proof of Theorem 1], we first observe that if \( G \) is an arrangement graph, there must be an integer \( \ell \) such that \( G \) has \( \ell(\ell - 1)/2 \) vertices (of degree \( d \in \{2, 3, 4\} \)) and \( \ell(\ell - 2) \) edges. This uniquely determines \( \ell \). We set the parameter \( k \) from the statement of our theorem to this value of \( \ell \). Again, as Chaplick et al., we construct a graph \( G' \) from \( G \) by appending a tail (i.e., a degree-1 vertex) to each degree-3 vertex of \( G \) and two tails to each degree-2 vertex of \( G \).

We claim that the following five conditions are equivalent: (i) \( G \) is an arrangement graph on \( k \) lines, (ii) \( \rho_1^2(G') \leq k \), (iii) \( \text{seg}_2(G') \leq k \), (iv) \( \text{seg}_\prec(G') \leq k \), and (v) \( \text{seg}_{\times}(G') \leq k \). Once the equivalence is established, the \( \exists \mathbb{R} \)-hardness of deciding (i) implies the \( \exists \mathbb{R} \)-hardness of deciding any of the other statements.

Indeed, according to Chaplick et al. [3, proof of Theorem 1], \( G \) is an arrangement graph if and only if \( \rho_1^2(G') \leq k \), that is, (i) and (ii) are equivalent.

Assume (i). If \( G \) corresponds to a line arrangement of \( k \) lines, all edges of \( G \) lie on these \( k \) lines and the tails of \( G' \) can be added without increasing the number of lines. This arrangement shows that \( \text{seg}_2(G') \leq k \), that is, (i) implies (iii).

Assume (iii), i.e., \( \text{seg}_2(G') \leq k \). Then \( \text{seg}_{\prec}(G') \leq k \) (iv) and \( \text{seg}_{\times}(G') \leq k \) (v).

Assume (iv), i.e., \( \text{seg}_{\prec}(G') \leq k \). Let \( \Gamma' \) be a polyline drawing of \( G' \) on \( \text{seg}_{\prec}(G') \) segments. The graph \( G' \) contains \( \binom{k}{2} \) degree-4 vertices. As each of these vertices lies on the intersection of two segments in \( \Gamma' \), we need \( k \) segments to get enough intersections, that is, \( \text{seg}_{\prec}(G') \geq k \). Thus \( \text{seg}_{\prec}(G') = k \) and each intersection of the segments of \( \Gamma' \) (in particular, each bend) is a vertex of \( G' \). Therefore edges in \( \Gamma' \) do not bend in interior points and \( \Gamma' \) witnesses that \( \text{seg}_2(G) \leq k \). Thus (iv) implies (ii).

Finally, assume (v), i.e., \( \text{seg}_{\times}(G') \leq k \). Let \( \Gamma \) be a straight-line drawing with possible crossings on \( \text{seg}_{\times}(G') \) segments. Again, we need \( k \) segments to get enough intersections, that is, \( \text{seg}_{\times}(G') \geq k \). Thus \( \text{seg}_{\times}(G') = k \) and each intersection of the segments of \( \Gamma \) is a vertex of \( G' \). Therefore edges in \( \Gamma \) do not cross and \( \Gamma \) witnesses that \( \text{seg}_2(G) \leq k \). Thus (v) implies (ii).

Summing up, (iii) implies (iv) and (v), which both imply (ii), which implies (i), which implies (iii). Hence, all statements are equivalent. \( \square \)

Theorem 2. Given a graph \( G \) and an integer \( k \), it is \( \exists \mathbb{R} \)-hard to decide whether \( \text{seg}_3(G) \leq k \).

Proof. Chaplick et al. [3, proof of Theorem 1] argued that for the graph \( G' \) constructed in the proof of Theorem 1 above, it holds that \( \rho_3^2(G') = \rho_1^3(G') \). Then, by the proof of Theorem 1, we have \( \rho_1^3(G') = \text{seg}_3(G') \).

By definition, we immediately obtain \( \text{seg}_3(G') \leq \rho_1^3(G') \). By Corollary 1 we have that \( \text{seg}_3(G') \leq \text{seg}_3(G) \). Therefore, \( \text{seg}_3(G') = \text{seg}_3(G) \). Together with the arguments in the proof of Theorem 1, this implies the theorem. \( \square \)

4 Algorithms and Lower Bounds for Cubic Graphs

Consider a polyline drawing \( \delta \) of a cubic graph (in 2D or 3D). Note that there are two types of vertices; those where exactly one segment ends and those where
three segments end. We call these vertices flat vertices and tripods, respectively. Let $f(\delta)$ be the number of flat vertices, $t(\delta)$ the number of tripods, and $b(\delta)$ the number of bends in $\delta$.

**Lemma 2.** For any straight-line drawing $\delta$ of a cubic graph with $n$ vertices, $\text{seg}(\delta) = \frac{3n}{2} - f(\delta) + b(\delta) = \frac{n}{2} + t(\delta) + b(\delta)$.

**Proof.** Clearly, $n = f(\delta) + t(\delta)$. The number of “segment ends” is $3t(\delta) + f(\delta) + 2b(\delta) = 3n - 2f(\delta) + 2b(\delta) = n + 2t(\delta) + 2b(\delta)$. The claim follows since every segment has two ends. □

### 4.1 Singly-Connected Cubic Graphs

**Proposition 2.** There is an infinite family $(G_k)_{k \geq 1}$ of connected cubic graphs such that $G_k$ has $n_k = 6k - 2$ vertices and $\text{seg}_3(G_k) = \text{seg}_\times(G_k) = 5k - 1 = \frac{5n_k}{6} + 2/3$.

**Proof.** Let $K'_4$ be the graph $K_4$ with a subdivided edge. Consider the graph $G_k$ depicted in Fig. 2 (for $k = 4$). It consists of a caterpillar with $k - 2$ inner vertices (of degree 3) where each of the $k$ leaf nodes is replaced by a copy of $K'_4$. The convex hull of every polyline drawing of $K'_4$ has at least three extreme points. One of these points may connect $K'_4$ to $G_k - K'_4$, but each of the remaining two must be a tripod or a bend. This holds for every copy of $K'_4$. Hence, for any drawing $\delta$ of $G$, $t(\delta) + b(\delta) \geq 2k$. Now Lemma 2 yields that $\text{seg}(\delta) \geq 5k - 1$. For the drawing in Fig. 2, the bound is tight. □

### 4.2 Biconnected Cubic Graphs

**Proposition 3.** There is an infinite family of Hamiltonian (and hence biconnected) cubic graphs $(H_k)_{k \geq 3}$ such that $H_k$ has $n_k = 6k$ vertices, $\text{seg}_3(H_k) = 5k = \frac{5n_k}{6}$, and $\text{seg}_\times(H_k) = 4k = \frac{2n_k}{3}$.

**Proof.** Consider the graph $H_k$ depicted in Fig. 3 (for $k = 4$). It is a $k$-cycle where each vertex is replaced by a copy of a 6-vertex graph $K$ ($K_{3,3}$ minus an edge). The graph $H_k$ has $n_k = 6k$ vertices and is not planar.

In any 2D drawing of the subgraph $K$, at least three vertices lie on the convex hull of the drawing of $K$. Two of these vertices may connect $K$ to $H_k - K$, but
at least one of the convex-hull vertices is a tripod. This holds for every copy of $K$. Hence, for any (3D) drawing $\delta$ of $H_k$, $t(\delta) \geq k$. Now Lemma 2 yields that $\seg(\delta) \geq n_k/2 + k = 2n_k/3$. The same bound holds for $\seg(H_k)$.

In order to bound $\seg(H_k)$ we consider two possibilities for the drawing of the subgraph $K$; either it lies in a plane or it doesn’t. In the planar case, the two vertices that connect $K$ to $H_k - K$ cannot lie in the same face of the planar embedding of $K$ (otherwise we could connect these two vertices without crossings, contradicting the fact that $K_{3,3}$ is not planar). Hence, at least two vertices on the convex hull of $K$ must be tripods. In the non-planar case, the convex hull consists of four vertices. Two of these may connect $K$ to $H_k - K$, but again at least two must be tripods. In both cases we hence have $t(\delta) \geq 2k$ for any 3D drawing $\delta$ of $H_k$. Now Lemma 2 yields $\seg(\delta) \geq n_k/2 + 2k = 3n_k/6$.

For the drawing in Fig. 3, the bound for $\seg$ is tight. Lifting the $k$ white vertices that do not lie on the outer face from the $xy$-plane ($z = 0$) to the plane $z = 1$, yields a crossing-free 3D drawing where the bound for $\seg$ is tight.

**Proposition 4.** There is an infinite family of planar cubic Hamiltonian (and hence biconnected) graphs $(I_k)_{k \geq 3}$ such that $I_k$ has $n_k = 4k$ vertices and $\seg_3(I_k) = \seg_\angle(I_k) = \seg_\times(I_k) = 3k = 3n_k/4$.

**Proof.** Consider the graph $I_k$ depicted in Fig. 4 (for $k = 9$). It is a $k$-cycle where each vertex is replaced by a copy of the graph $K'$, which is $K_4$ minus an edge. Therefore, $I_k$ has $4k$ vertices. The depicted drawing consists of $3k$ segments. This yields the upper bounds.

Concerning the lower bounds, note that, in any drawing style, each subgraph $K'$ has an extreme point not connected to $I_k - V(K')$. This point must be a tripod or a bend. Hence, in any drawing $\delta$ of $I_k$, $t(\delta) + b(\delta) \geq k$ and, by Lemma 2, $\seg_2(I_k) = \seg_3(I_k) = \seg_\angle(I_k) = \seg_\times(I_k) \geq 2k + t(\delta) + b(\delta) \geq 3k$. □

**Theorem 3.** For any biconnected planar cubic graph $G$ with $n$ vertices, it holds that $\seg_\angle(G) \leq n + 1$. A corresponding drawing can be found in linear time.

---

**Fig. 3:** The cubic graph $H_k$ (here $k = 4$) is a $k$-cycle whose vertices are replaced by $K_{3,3}$ minus an edge (shaded).

**Fig. 4:** The planar cubic graph $I_k$ (here $k = 9$) is a $k$-cycle whose vertices are replaced by $K_4$ minus an edge (shaded).
Proof. We draw $G$ using the algorithm of Liu et al. [13] that draws any planar biconnected cubic graph except the tetrahedron orthogonally with at most one bend per edge and at most $n/2 + 1$ bends in total. It remains to count the number of segments in this drawing. In any vertex exactly one segment ends; in any bend exactly two segments end. In total, this yields at most $n + 2 \cdot (n/2 + 1) = 2n + 2$ segment ends and at most $n + 1$ segments.

Concerning the special case of the tetrahedron ($K_4$), note that it can be drawn with five segments when bending one of its six edges. $\Box$

Open Problem 2 What about 4-regular graphs? They have $2n$ edges. If we bend every edge once, we already need $2n$ segments – and not all 4-regular graphs can be drawn with at most one bend per edge.

Every biconnected graph $G$ admits an $st$-numbering, that is, an ordering $\langle v_1, \ldots, v_n \rangle$ of the vertex set $\{ v_1, \ldots, v_n \}$ of $G$ such that for every $j \in \{ 2, \ldots, n-1 \}$ vertex $v_j$ has at least one predecessor (that is, a neighbor $v_i$ with $i < j$) and at least one successor (that is, a neighbor $v_k$ with $k > j$). Such a numbering can be computed in linear time [9]. Given a cubic graph with an $st$-numbering $\langle v_1, \ldots, v_n \rangle$, we call a vertex $v_j$ with $j \in \{ 1, \ldots, n \}$ a $p$-vertex if it has $p$ predecessors; $p \in \{ 0, 1, 2, 3 \}$.

Lemma 3. Given a biconnected cubic graph with an $st$-numbering $\langle v_1, \ldots, v_n \rangle$, there is one 0-vertex and one 3-vertex and there are $(n-2)/2$ 1-vertices and $(n-2)/2$ 2-vertices.

Proof. Direct every edge from the vertex with smaller index to the vertex with higher index. In the resulting directed graph, the sum of the indegrees equals the sum of the outdegrees. Hence, the number of 1-vertices (with indegree 1 and outdegree 2) and the number of 2-vertices (with indegree 2 and outdegree 1) must be equal. It is obvious that there is one 0- and 3-vertex each. $\Box$

Theorem 4. For any biconnected cubic graph $G$ with $n$ vertices, $seg_3(G) \leq n+2$ and $seg_x(G) \leq n + 2$.

Proof. We show that $seg_3(G) \leq n + 2$. Then Corollary 1 yields $seg_x(G) \leq n + 2$. For two different points $x$ and $y$ in $\mathbb{R}^3$, we denote the line that goes through $x$ and $y$ by $xy$.

Let $\langle v_1, \ldots, v_n \rangle$ be an $st$-numbering of $G$. We construct a drawing $\delta$ of $G$, going through the vertices according to the $st$-numbering and using x-coordinate $j \pm \varepsilon$ for vertex $v_j$, where $0 < \varepsilon \ll 1$. We place $v_1$ at $(1,1,1)$. At every step $j = 2, \ldots, n$, we maintain a set $\mathcal{L}$ of lines that are directed to the right such that any two lines in $\mathcal{L}$ are either skew (that is, they don’t lie in the same plane) or they intersect and their unique intersection point is the location of a vertex $v_k$ with $k \leq j$ (that is, the intersection point is $v_j$ or it lies to the left of $v_j$). Initially, $\mathcal{L}$ is empty.

If $v_j$ is a 1-vertex, we differentiate two cases depending on the unique predecessor $v_i$ of $v_j$.
Case I: If \( v_i \) is the last vertex on a line \( \ell \) in \( L \), we place \( v_j \) on the intersection point of \( \ell \) with the plane \( x = j \). In this case, the set \( L \) doesn’t change.

Case II: Otherwise, we place \( v_j \) in the plane \( x = j \) such that the line \( v_iv_j \) is skew with respect to all lines in \( L \) except for the line \( \ell \) that contains \( v_i \) and the unique predecessor of \( v_i \). (Note that the predecessor of \( v_i \) and the line \( \ell \) don’t exist if \( i = 1 \).) Clearly, \( v_iv_j \) and \( \ell \) intersect in \( v_i \) and \( i < j \). Hence, we can add the line \( v_iv_j \) to the set \( L \).

If \( v_j \) is a 2-vertex, let \( v_i \) and \( v_i' \) be the two predecessors of \( v_j \). Again, we consider two cases.

Case I: At least one of \( v_i \) or \( v_i' \) is flat (that is, it lies on an inner point of the segment created by its incident edges that have already been drawn) or one of them is the vertex \( v_1 \).

In this case, we treat \( v_j \) similarly as in Case II above; we make sure that the lines \( v_iv_j \) and \( v_i'v_j \) are skew with respect to all lines in \( L \) except that \( v_iv_j \) won’t be skew with respect to the at most two lines that connect \( v_i \) to its predecessors and \( v_i'v_j \) won’t be skew with respect to the at most two lines that connect \( v_i' \) to its predecessors. Note that \( v_i'v_j \) intersects any line through \( v_i \) and its neighbors in \( v_i \), and it holds that \( i < j \). Similarly, \( v_i'v_j \) intersects any line through \( v_i' \) and its neighbors in \( v_i' \), and it holds that \( i' < j \). The lines \( v_i'v_j \) and \( v_i'v_j \) intersect in \( v_j \). Hence, we can add the lines \( v_iv_j \) and \( v_i'v_j \) to the set \( L \).

Case II: Both \( v_i \) and \( v_i' \) are the last vertices on their lines \( \ell \) and \( \ell' \), respectively.

If one of them, say \( v_i \), has a successor \( v_k \) with \( k > j \), we extend the line \( \ell \) of \( v_i \) and put \( v_j \) on the intersection of \( \ell \) and the plane \( x = j \).

Otherwise \( v_i \) has a successor \( v_k \) with \( k < j \) and \( v_i' \) has a successor \( v_{k'} \) with \( k' < j \), which both don’t lie on the lines \( \ell \) and \( \ell' \). In this case, we put \( v_j \) on one of \( \ell \) and \( \ell' \), say \( \ell \), and add the line \( v_{i'}v_j \) to the set \( L \). Now we pick some \( 0 < \varepsilon \ll 1 \) such that we can place \( v_j \) at the intersection of \( \ell \) and \( x = j + \varepsilon \). We must avoid to place \( v_j \) on a plane spanned by any two non-skew lines in \( L \) (intersecting to the left of \( x = j \)). With this trick, the invariant for \( L \) still holds since the new line in \( L \), \( v_{i'}v_j \), intersects only \( \ell' \) (in \( v_{i'} \), hence to the left).

Finally, we place \( v_n \) (which is a 3-vertex) at a point in the plane \( x = n \) that does not lie on any of the lines spanned by pairs and planes spanned by triples of previously placed vertices.

This finishes the description of the drawing \( \delta \) of \( G \). Due to our invariant regarding the set \( L \), no two edges of \( G \) intersect in \( \delta \).

To bound the number of segments in \( \delta \), we use a simple charging argument. Each non-first and non-last vertex \( v \) has a predecessor which is a flat vertex or \( v_1 \). To this predecessor \( v \) pays a coin. On the other hand, \( v_1 \) receives at most three coins and every flat vertex receives at most two coins. Hence, \( f(\delta) \geq (n - 5)/2 \). Since \( n \) is even, \( f(\delta) \geq n/2 - 2 \). Now, Lemma \( 2 \) yields the claim.

4.3 Triconnected Cubic Graphs

Proposition 5. There is an infinite family of triconnected cubic graphs \( (F_k)_{k \geq 4} \) such that \( F_k \) has \( n_k = 5k \) vertices and \( \text{seg}_3(F_k) = 3.5k = 7n_k/10 \).
Variants of the Segment Number of a Graph

Proof. Let $G_k$ be an arbitrary triconnected cubic graph with $k$ vertices ($k$ even). By Steinitz’s theorem, there exists a drawing of the graph $G_k$ as a 1-skeleton of a 3D convex polyhedron. Replace each vertex $v$ of $G_k$ by a copy of $K_{2,3}$ as shown at Fig. 5 where $v$ is the central (orange) vertex—a tripod—, all other vertices of the copy are flat, and the three arrows correspond to the three edges of $G_k$. The resulting geometric graph $F_k$ has $n_k = 5k$ vertices and is not planar. Since $F_k$ has $k$ tripod vertices, by Lemma 2, $\text{seg}_3(F_k) \leq n_k/2 + k = 3.5k = 7n_k/10$.

In order to bound $\text{seg}_3(F_k)$ from below, we consider two possibilities for the drawing of each subgraph $K_{2,3}$; either it lies in a plane or it doesn’t. In the planar case, the convex hull of the drawing has at least three extreme points. If none of them was a tripod then there would be exactly three extreme points, each a black vertex. Thus we could place an additional white vertex in the exterior of the convex hull and connect it to all black vertices, obtaining an impossible plane drawing of $K_{3,3}$. In the non-planar case, the convex hull consists of at least four vertices. Three of these may connect $K_{2,3}$ to $F_k - V(K_{2,3})$, but again at least one must be a tripod.

In both cases we hence have $t(\delta) \geq k$ for any 3D drawing $\delta$ of $F_k$. Now Lemma 2 yields $\text{seg}(\delta) = n_k/2 + t(\delta) \geq 3.5k$.

5 Open Problems

Apart from improving our bounds, we have the following open problem.

Open Problem 3 Can we produce drawings in 3D (or with bends or crossings in 2D) that fit on grids of small size?

Acknowledgments. We thank organizers and participants of the 2019 Dagstuhl seminar “Beyond-planar graphs: Combinatorics, Models and Algorithms”. In particular, we thank Günter Rote and Martin Gronemann for asking interesting questions that led to some of this research. We also thank Carlos Alegría. We thank our reviewers for a construction that improved the bound in Proposition 5, for suggesting Lemma 1, and for many other helpful comments.
