An inexact augmented Lagrangian method for nonsmooth optimization on Riemannian manifold

Kang-Kang Deng †, Zheng Peng ‡‡

Abstract: We consider a nonsmooth optimization problem on Riemannian manifold, whose objective function is the sum of a differentiable component and a nonsmooth convex function. The problem is reformulated to a separable form. We propose a manifold inexact augmented Lagrangian method (MIALM) for the considered problem. By utilizing the Moreau envelope, we get a smoothing subproblem at each iteration of the proposed method. Theoretically, the convergence to critical point of the proposed method is established under suitable assumptions. In particular, if an approximate global minimizer of the iteration subproblem is obtained at each iteration, we prove that the sequence generated by the proposed method converges to a global minimizer of the origin problem. Numerical experiments show that, the MIALM is a competitive method compared to some existing methods.

Keywords: Manifold optimization; Nonsmooth optimization; Augmented Lagrangian method; Moreau envelope.

Mathematics Subject Classification: 90C30, 90C26

1 Introduction

Riemannian manifold optimization is a class of constrained optimization problems, in which the constraint set is a subset of Riemannian manifold $\mathcal{M}$. It has recently aroused considerable research interests due to the wide applications in different fields such as computer vision, signal processing, etc \(\S\). In these applications, manifold $\mathcal{M}$ could be Stiefel manifold, Grassmann manifold, or symmetric positive definite manifold. Analogy to classical optimization methods in Euclidean space, some Riemannian optimization methods have been explored, e.g., gradient-
type methods, Newton-type methods and trust region methods. In this paper, we consider a nonsmooth nonconvex Riemannian manifold optimization problem as follows

$$\begin{align*}
\min_{X \in \mathbb{R}^{n \times r}} & \quad F(X) := f(X) + g(AX) \\
\text{s.t.} & \quad X \in \mathcal{M},
\end{align*}$$

(1.1)

where $f : \mathcal{M} \to \mathbb{R}$ is a smooth but possibly nonconvex function, $g$ is convex but nonsmooth, and $\mathcal{M}$ is a Riemannian submanifold embedded in Euclidean space $\mathbb{E}$. Many convex or nonconvex problems in machine learning applications have the form of problem (1.1), e.g., sparse principle component analysis, sparse canonical correlation analysis, robust low-rank matrix completion and multi-antenna channel communications, etc.

Absil and Hosseini presented many examples of manifold optimization with nonsmooth objective. We list three representative examples in the following.

Example 1.1 (Sparse principle component analysis (SPCA)).

$$\begin{align*}
\min_{X \in \mathbb{R}^{n \times r}} & \quad -X^T A^T A X + \lambda \|X\|_1 \\
\text{s.t.} & \quad X^T X = I_r.
\end{align*}$$

(1.2)

Example 1.2 (Compressed modes in physics (CMs)).

$$\begin{align*}
\min_{\Psi \in \mathbb{R}^{n \times r}} & \quad tr(\Psi^T \Delta \Psi) + \mu \|\Psi\|_1 \\
\text{s.t.} & \quad \Psi^T \Psi = I_r.
\end{align*}$$

(1.3)

Example 1.3 (Robust low-rank matrix completion).

$$\begin{align*}
\min_{X \in \mathbb{R}^{n \times n}} & \quad \|P_2 (X - M)\|_1 \\
\text{s.t.} & \quad X \in \mathcal{M}_r := \{X| \text{ rank } (X) = r\}.
\end{align*}$$

(1.4)

Problem (1.1) is reformulated to a separable form in this paper, and then a manifold inexact augmented Lagrangian method (MIALM) is proposed for the resulting separable optimization problem. The iteration subproblem of the MIALM is formulated to a smooth optimization problem by utilizing the Moreau envelope, it could be solved by some classical Riemannian optimization methods such as Riemannian gradient/Newton/Quasi-Newton method. This algorithmic framework is adapted from classical nonsmooth composite problem in Euclidean space, which has drawn significant research attentions. The convergence to critical point of the proposed MIALM method is established under some mild assumptions. In particular, under the assumption that an approximate global minimizer of the iteration subproblem
could be obtained, the convergence to global minimizer of the original problem is proved. Numerical experiments show that, the MIALM is competitive compared to some existing methods.

The rest of this paper is organized as follows. Some related works on nonsmooth manifold optimization problem are summarized in Section 2 and some preliminaries on manifold are given in Section 3. In Section 4 a manifold inexact augmented Lagrangian method is proposed and the iteration subproblem solver is presented. The convergence of the proposed method is established in Section 5. Numerical results on compressed modes problems in physics and sparse PCA are reported in Section 6. Finally, Section 7 concludes this paper by some remarks.

2 Related works

We summarize some related works for nonsmooth optimization problem on manifold in this section. The existing results mainly focused on two classes of nonsmooth manifold optimization problem: nonsmooth optimization problem with locally Lipschitz objective function, and structured optimization problem having the form of problem (1.1).

Grohs and Hosseini [21] proposed the $\varepsilon$-subgradient algorithm for minimizing a locally Lipschitz function on Riemannian manifold. By utilizing $\varepsilon$-subgradient-oriented descent directions and the generalized Wolfe line-search on Riemannian manifold, Hosseini, Huang and Yousefpour [24] presented a nonsmooth Riemannian line search algorithm and established the convergence to a stationary point. Grohs [20] presented a nonsmooth trust region algorithm for minimizing locally Lipschitz objective function on Riemannian manifold. The iteration complexity of these subgradient algorithms was also investigated in [5] and [18]. In [25] and [12], the authors proposed the Riemannian gradient sampling algorithms. At each iteration of these Riemannian gradient sampling methods, the subdifferential of the objective function is approximated by the convex hull of transported gradients of nearby points, and the nearby points are randomly generated in the tangent space of the current iterate.

Some proximal point algorithms on Riemannian manifold were investigated in the recent. Bento, Ferreira and Melo [5] analyzed the iteration complexity of a proximal point algorithm on Hadamard manifold having non-positive sectional curvature. Bento, et al [16] gave the full convergence for any bounded sequence generated by the proximal point method, without assumption on the sign of the sectional curvature on manifold. The Kurdyka-Łojasiewicz inequality on Riemannian manifold is a powerful tool for convergence analysis of optimization methods on manifold. Bento, et al [6] analyzed the full convergence of a steepest descent method and a proximal point method via Kurdyka-Łojasiewicz inequality. Seyedehsomayeh [23] pro-
posed a subgradient-oriented descent method and proved that, if the objective function has the Kurdyka-Łojasiewicz property, the sequence generated by the subgradient-oriented descent method converges to a singular critical point.

By a separable reformulation of problem (1.1), the variable involving Riemannian manifold constraint and that one involving nonsmooth term could be handled separately. To do so, it results in two tractable subproblems. Based on this idea, Lai, et al [30] proposed a splitting of orthogonality constraints (SOC) method for a special case of problem (1.1), in which \( f \equiv 0 \) and \( A = I \), \( \mathcal{M} \) is a Stiefel manifold. That is

\[
\begin{cases}
\min_X g(X), \\
\text{s.t. } X \in \mathcal{M}.
\end{cases}
\] (2.1)

To solve problem (2.1), the SOC method considered the following separable reformulation:

\[
\begin{cases}
\min_{X,Y} g(Y), \\
\text{s.t. } X \in \mathcal{M}, X = Y.
\end{cases}
\] (2.2)

The associated partial augmented Lagrangian function is

\[
\mathcal{L}_\beta := g(Y) - \langle \Lambda, X - Y \rangle + \frac{\beta}{2} \|X - Y\|^2_F
\] (2.3)

where \( \Lambda \) is the Lagrangian multiplier, and \( \beta \) is a penalty parameter. The SOC method updates iterate via

\[
\begin{cases}
X^{k+1} = \arg\min_{X \in \mathcal{M}} \frac{\beta}{2} \|X - Y^k - \frac{1}{\beta} \Lambda^k\|^2_F, \\
Y^{k+1} = \arg\min_{Y} g(Y) + \frac{\beta}{2} \|X^{k+1} - Y - \frac{1}{\beta} \Lambda^k\|^2_F, \\
\Lambda^{k+1} = \Lambda^k - \beta(X^{k+1} - Y^{k+1}).
\end{cases}
\] (2.4)

The \( X \)-subproblem is “easy” via projection on \( \mathcal{M} \), and the \( Y \)-subproblem is often structured in real applications.

Chen, et al [15] proposed a proximal alternating minimization augmented Lagrangian (PAMAL) method of multipliers for problem (1.1) with \( A = I \) and \( \mathcal{M} = St_n \). Specifically, the PAMAL method first reformulates the problem to:

\[
\begin{cases}
\min_{X,Y,Q} f(Y) + h(Q), \\
\text{s.t. } X = Y, X = Q, X \in \mathcal{M}.
\end{cases}
\] (2.5)

Then it considers the augmented Lagrangian method of multipliers framework aiming to obtain
the solution for the jointed variable \((X, Y, Q)\) at each iteration. The iterate is produced by

\[
\begin{aligned}
(X^{k+1}, Y^{k+1}, Q^{k+1}) &= \arg \min_{X, Y, Q} L_\beta(X, Y, Q; \Lambda^k_1, \Lambda^k_2), \\
\Lambda^k_1 &= \Lambda^k - \beta(X^{k+1} - Y^{k+1}), \\
\Lambda^k_2 &= \Lambda^k - \beta(X^{k+1} - Q^{k+1}),
\end{aligned}
\]

(2.6)

where \(L_\beta\) is the augmented Lagrangian function associated to (2.5). The subproblem on the jointed variable \((X, Y, Q)\) is intractable, hence the authors proposed a proximal alternating minimization method to handle it. Hong, et al [22] considered a more general form where \(M\) is the generalized orthogonal constraint, and proposed a PAMAL-type algorithm in which a proximal alternating linearized minimization method was used for iteration subproblem.

Kovnatsky, et al [29] proposed a manifold ADMM (MADMM) for a general manifold optimization problem as follows

\[
\begin{aligned}
\min_{X, Y} f(X) + g(Y) \\
\text{s.t. } AX = Y, X \in M.
\end{aligned}
\]

(2.7)

The associated partial augmented Lagrangian function is

\[
L_\beta(X, Y; \Lambda) := f(X) + g(Y) - \langle \Lambda, AX - Y \rangle + \frac{\beta}{2} \|AX - Y\|^2_F.
\]

The MADMM has the iterate as follows

\[
\begin{aligned}
X^{k+1} &= \arg \min_{X \in M} L_\beta(X, Y^k, \Lambda^k) \\
Y^{k+1} &= \arg \min_{Y} L_\beta(X^{k+1}, Y, \Lambda^k) \\
\Lambda^{k+1} &= \Lambda^k - \beta(AX^{k+1} - Y^{k+1})
\end{aligned}
\]

(2.8)

More recently, Chen, et al [14] proposed a manifold proximal gradient method (ManPG) for problem (1.1) with \(A = I\), i.e.

\[
\min_X f(X) + g(X), \text{ s.t. } X \in M
\]

(2.9)

At the \(k\)-th iteration, the search direction \(D^k\) of ManPG is obtained by

\[
\begin{aligned}
\min_D \langle D, \grad f(X^k) \rangle + \frac{\beta}{2} \|D\|_F^2 + g(X^k + D), \\
\text{s.t. } D \in T_{X^k}M,
\end{aligned}
\]

(2.10)

where \(D \in T_{X^k}M\) can be represented by a linear system \(A_k(D) = 0\). The subproblem (2.10) is solved by applying the semi-smooth Newton method to the KKT system. The next iterate \(X^{k+1}\) is then obtained by

\[
X^{k+1} = R_{X^k}(\alpha_k D^k).
\]
3 Preliminaries

3.1 Riemannian manifold optimization

Let $\mathcal{M}$ be a smooth manifold, and $\mathbb{E}$ be the Euclidean space. The tangent space of $\mathcal{M}$ at $x \in \mathcal{M}$ is denoted by $T_x \mathcal{M}$. A Riemannian manifold $(\mathcal{M}, \langle \cdot, \cdot \rangle)$ is a smooth manifold equipped with inner product $\langle \cdot, \cdot \rangle_x$ on each point $x \in \mathcal{M}$. Let $(U, \varphi)$ be a chart, where $U$ is an open set with $x \in U \subset \mathcal{M}$ and $\varphi$ is a homeomorphism between $U$ and open set $\varphi(U) \subset \mathbb{E}$. Given a Riemannian manifold $\mathcal{M}$, the chart exists at each point $x \in \mathcal{M}$.

**Definition 3.1 (Riemannian Gradient).** Riemannian gradient, denoted by $\text{grad} f(x) \in T_x \mathcal{M}$, is the unique tangent vector satisfying

$$\langle \text{grad} f(x), \xi_x \rangle = df(x)[\xi], \quad \forall \xi \in T_x \mathcal{M}. \quad (3.1)$$

If $\mathcal{M}$ is an embedded manifold of $\mathbb{E}$, the Riemannian metric between $u, v \in T_x \mathcal{M}$ could be introduced by an inner product in $\mathbb{E}$, i.e. $\langle u, v \rangle_x = \langle u, v \rangle$, where the later is classical inner product in $\mathbb{E}$. In the sense, we have

$$\text{grad} f(x) = \text{Proj}_{T_x \mathcal{M}}(\nabla f(x)) \quad (3.2)$$

where $\nabla f(x)$ is the gradient in $\mathbb{E}$, $\text{Proj}_{T_x \mathcal{M}}$ is a projection on tangent space $T_x \mathcal{M}$.

**Definition 3.2 (Riemannian Hessian).** Given a smooth function $f : \mathcal{M} \to \mathbb{R}$, the Riemannian Hessian of $f$ at $x$ in $\mathcal{M}$ is linear mapping $\text{Hess} f(x)$ of $T_x \mathcal{M}$ into itself, defined by

$$\text{Hess} f(x)[\xi_x] = \nabla_{\xi_x} \text{grad} f(x) \quad (3.3)$$

for $\forall \xi_x \in T_x \mathcal{M}$, where $\nabla$ is the Riemannian connection on $\mathcal{M}$.

**Definition 3.3 (Retraction).** A retraction on manifold $\mathcal{M}$ is a smooth mapping $R : T \mathcal{M} \to \mathcal{M}$ which has the following properties: let $R_x : T_x \mathcal{M} \to \mathcal{M}$ be the restriction of $R$ to $T_x \mathcal{M}$, then

- $R_x(0_x) = x$, where $0_x$ is zero element of $T_x \mathcal{M}$
- $dR_x(0_x) = id_{T_x \mathcal{M}}$, where $id_{T_x \mathcal{M}}$ is the identity mapping on $T_x \mathcal{M}$

**Definition 3.4 (Vector Transport).** The vector transport $\mathcal{T}$ is a smooth mapping with

$$T \mathcal{M} \oplus T \mathcal{M} \to T \mathcal{M} : (\eta_x, \xi_x) \mapsto \mathcal{T}_{\eta_x}(\xi_x) \in T \mathcal{M}, \forall x \in \mathcal{M}, \quad (3.4)$$

where $\mathcal{T}$ satisfies that
\[-T_0, \xi_x = \xi_x \text{ holds for } \forall \xi_x \in T_x \mathcal{M};\]

\[-T_\eta_x (a\xi_x + b\xi_x) = aT_\eta_x (\xi_x) + bT_\eta_x (\xi_x).\]

**Definition 3.5** (The Clarke subdifferential on Riemannian manifold). For a locally Lipschitz continuous function \(f\) on \(\mathcal{M}\), the Riemannian generalized directional derivative of \(f\) at \(x \in \mathcal{M}\) in direction \(v \in T_x \mathcal{M}\) is given by

\[
f^\circ(x; v) = \lim_{y \to x \sup t \downarrow 0} \frac{f \circ \varphi^{-1}(\varphi(y) + tD\varphi(y)[v]) - f \circ \varphi^{-1}(\varphi(y))}{t},
\]

where \((\varphi, \mathcal{U})\) is coordinate chart at \(x\). The generalized gradient or the Clarke subdifferential of \(f\) at \(x \in \mathcal{M}\) is

\[
\partial f(x) = \{\xi \in T_x \mathcal{M} : (\xi, v)_x \leq f^\circ(x; v), \forall v \in T_x \mathcal{M}\}. \tag{3.6}
\]

Consider a Riemannian manifold minimization problem

\[
\begin{array}{ll}
\min_x & f(x) \\
\text{s.t.} & c_i(x) = 0, i = 1, \cdots, m, \\
& x \in \mathcal{M}.
\end{array} \tag{3.7}
\]

Let \(\Omega := \{x \in \mathcal{M} : c_i(x) = 0, i = 1 \cdots, m\}\). Given \(x^* \in \Omega\), assume that the Linear Independent Constraint Qualification (LICQ) holds at \(x^*\), then normal cone \(N_{\Omega}(x^*)\) is

\[
N_{\Omega}(x^*) = \left\{ \sum_{i=1}^{m} \lambda_i \text{grad} c_i(x^*) \middle| \lambda \in \mathbb{R}^m \right\} \tag{3.8}
\]

For the first-order optimality condition of problem \(3.7\), we have

**Lemma 3.1** ([38], Proposition 2.7). If \(x^* \in \Omega\), and

\[
\partial f(x^*) \cap (-N_{\Omega}(x^*)) \neq \emptyset, \tag{3.9}
\]

then \(x^*\) is a stationary solution of problem \(3.7\).

### 3.2 Proximal operator and retraction-smooth

For a proper, convex and low semicontinuous function \(g : \mathcal{E} \to \mathbb{R}\), the proximal operator with parameter \(\mu \geq 0\), denoted by \(\text{prox}_{\mu g}\), is defined by

\[
\text{prox}_{\mu g}(v) := \arg \min_x \{g(x) + \frac{1}{2\mu} \|x - v\|^2\}. \tag{3.10}
\]
The associated Moreau envelope is a function $M : \mathbb{E} \to \mathbb{R}$ given by
\[
M_\mu g(v) := \min_x \{ g(x) + \frac{1}{2\mu} \|x - v\|^2 \} = g(\text{prox}_\mu g(v)) + \frac{1}{2\mu} \|\text{prox}_\mu g(v) - v\|^2.
\] (3.11)

The Moreau envelope is a continuously differentiable function, even when $g$ is not.

**Lemma 3.2** (Theorem 6.60 in [4]). Let $g : \mathbb{E} \to \mathbb{R}$ be a proper closed and convex function, and $\mu \geq 0$. Then $M_\mu g$ is $\frac{1}{\mu}$-smooth in $\mathbb{E}$, and for $\forall \ v \in \mathbb{E}$ one has
\[
\nabla M_\mu g(v) = \frac{1}{\mu} (v - \text{prox}_\mu g(v)).
\] (3.12)

Lemma 3.2 states that, the Moreau envelope is continuously differentiable in Euclidean space $\mathbb{E}$. Next we will show the relationship between Retraction smoothness in submanifold of Euclidean space and smoothness in Euclidean space.

**Definition 3.6** (Retraction-Smooth). A function $f : \mathcal{M} \to \mathbb{R}$ is said to be retraction $\ell$-smooth if, for $\forall \ x, y \in \mathcal{M}$ it holds that
\[
f(y) \leq f(x) + \langle \nabla f(x), \xi \rangle_x + \frac{\ell}{2} \|\xi\|^2_x,
\] (3.13)

where $\xi \in T_x \mathcal{M}$ and $R_x(\xi) = y$.

Let $\mathcal{M}$ be a Riemannian submanifold of $\mathbb{E}$. The following lemma states that, if $f : \mathbb{R}^n \to \mathbb{R}$ has Lipschitz continuous gradient, then $f$ is also retraction smooth on $\mathcal{M}$.

**Lemma 3.3.** [Lemma 4 in [10]] Let $\mathbb{E}$ be a Euclidean space (for example, $\mathbb{E} = \mathbb{R}^n$) and $\mathcal{M}$ be a compact Riemannian submanifold of $\mathbb{E}$. If $f : \mathbb{E} \to \mathbb{R}$ has Lipschitz continuous gradient in the convex hull of $\mathcal{M}$, then there exists a positive constant $\ell_g$ such that
\[
f(R_{x_k}(\eta)) \leq f(x_k) + \langle \eta, \nabla f(x_k) \rangle + \frac{\ell_g}{2} \|\eta\|^2
\] (3.14)
holds at $\forall \ \eta \in T_{x_k} \mathcal{M}$.

Lemma 3.3 was proved in [10]. For the sake of completeness, we give a proof as follows.

**Proof.** By Lipschitz continuity, $\nabla f$ is Lipschitz along any line segment in $\mathbb{E}$ jointing $x$ and $y$. Hence, there exists $\ell > 0$ such that
\[
f(y) \leq f(x) + \langle \nabla f(x), y - x \rangle + \frac{\ell}{2} \|y - x\|^2, \ \forall x, y \in \mathcal{M}.
\] (3.15)
It also holds if $y = R_x(\eta), \forall \eta \in T_x\mathcal{M}$. Since $\text{grad} f(x)$ is a orthogonal projection of $\nabla f(x)$ on $T_x\mathcal{M}$, we have
\[
\langle \nabla f(x), R_x(\eta) - x \rangle = \langle \nabla f(x), \eta + R_x(\eta) - x - \eta \rangle = \langle \text{grad} f(x), \eta \rangle + \langle \nabla f(x), R_x(\eta) - x - \eta \rangle. 
\] (3.16)

It is easy to deduce from (3.15) and (3.16) that
\[
f(R_x(\eta)) \leq f(x) + \langle \text{grad} f(x), \eta \rangle + \frac{\ell}{2} \|R_x(\eta) - x\|^2 + \|\nabla f(x)\| \|R_x(\eta) - x - \eta\|. 
\]

Since $\nabla f(x)$ is continuous on compact set $\mathcal{M}$, there exists $G > 0$ such that $\|\nabla f(x)\| \leq G, \forall x \in \mathcal{M}$. By Definition 3.3 and the compactness of manifold, there exists $\alpha, \beta \geq 0$ such that, for all $x \in \mathcal{M}$ and all $\eta \in T_x\mathcal{M}$, we have
\[
\|R_x(\eta) - x\| \leq \alpha \|\eta\|^2, \text{ and } \|R_x(\eta) - x - \eta\| \leq \beta \|\eta\|^2.
\]
Hence
\[
f(R_x(\eta)) \leq f(x) + \langle \text{grad} f(x), \eta \rangle + \left(\frac{\ell}{2} \alpha^2 + G \beta\right) \|\eta\|^2.
\]
Let $\ell_g = \left(\frac{\ell}{2} \alpha^2 + G \beta\right)$, we have (3.14) and complete the proof. \qed

4 The proposed method

4.1 Problem reformulation

For regularity, we need the following assumptions on problem (1.1).

Assumption 4.1.

A. $\mathcal{M}$ is a compact Riemannian submanifold embedded in Euclidean space $\mathbb{E}$;

B. $f$ is smooth but not necessary convex, $g$ is a nonsmooth convex function on $\mathbb{E}$, $A \in \mathbb{R}^{d \times n}$ and $\partial g(Y)$ is uniformly bounded for $\forall Y \in \mathbb{R}^{d \times r}$, where $\partial g(Y)$ is subdifferential of $g$ at $Y$.

By introducing auxiliary variable $Y = AX$, problem (1.1) can be reformulated to
\[
\begin{align*}
\min_{X,Y} & \quad f(X) + g(Y) \\
\text{s.t.} & \quad AX = Y, \ X \in \mathcal{M}.
\end{align*}
\] (4.1)

The partial Lagrangian function associated to problem (4.1) is
\[
L(X, Y; Z) := f(X) + g(Y) - \langle Z, AX - Y \rangle
\] (4.2)

By Lemma 3.1, the KKT system of problem (4.1) is as follows:
Proposition 4.1. Suppose in problem (4.1) that $f$ is smooth with Lipschitz continuous gradient and $g$ is convex and locally Lipschitz continuous. Then, $(X^*, Y^*)$ satisfies the KKT conditions if there exists a Lagrange multiplier $Z^*$ such that

$$
\begin{align*}
0 &\in \text{Proj}_{T_{X^*}M}(\nabla f(X^*) - A^T Z^*), \\
0 &\in \partial g(Y^*) + Z^*, \\
AX^* &\neq Y^*.
\end{align*}
$$

(4.3)

4.2 Manifold inexact augmented Lagrangian method

The augmented Lagrangian associated with (4.1) is

$$
L_\rho(X, Y; Z) = L(X, Y; Z) + \frac{\rho}{2} \|AX - Y\|_F^2
$$

$$
= f(X) + g(Y) - \langle Z, AX - Y \rangle + \frac{\rho}{2} \|AX - Y\|_F^2.
$$

(4.4)

For a given $(X^k, Y^k, Z^k)$, the next iterate generated by our manifold inexact augmented Lagrangian method (MIALM) is given by

$$
\begin{align*}
(X^{k+1}, Y^{k+1}) &= \text{arg min}_{X \in M, Y} L_\rho(X, Y; Z^k), \\
Z^{k+1} &= Z^k - \rho(A X^{k+1} - Y^{k+1}).
\end{align*}
$$

(4.5)

The $(X, Y)$- subproblem is intractable due to the nonsmoothess and joint minimization. Hence, an efficient Riemannian optimization method should be proposed for this subproblem in MIALM (4.5). Notice that, for fixed $\rho > 0$ and $Z$ we aim to solve

$$
\min_{X \in M, Y \in \mathbb{R}^{d \times r}} \Psi(X, Y) := L_\rho(X, Y; Z)
$$

(4.6)

Let

$$
\psi_Z(X) := \inf_Y \Psi(X, Y)
$$

$$
= f(X) + g(\text{Prox}_{g/\rho}(AX - \mu Z)) + \frac{\rho}{2} \|AX - \frac{1}{\rho} Z - \text{Prox}_{g/\rho}(AX - \frac{1}{\rho} Z)\|_F^2 - \frac{1}{2\rho} \|Z\|_F^2.
$$

(4.7)

The new iterate $(\bar{X}, \bar{Y})$ could be produced sequentially by

$$
\bar{X} = \arg \min_{X \in M} \psi_Z(X), \quad \bar{Y} = \text{Prox}_{g/\rho}(A \bar{X} - \frac{1}{\rho} Z).
$$

(4.8)

In the sense, the MIALM iterate is rewritten to

$$
\begin{align*}
X^{k+1} &= \arg \min_{X \in M} \psi_Z(X), \\
Y^{k+1} &= \text{Prox}_{g/\rho}(AX^{k+1} - \frac{1}{\rho} Z^k), \\
Z^{k+1} &= Z^k - \rho(A X^{k+1} - Y^{k+1}).
\end{align*}
$$

(4.9)
By (3.12), we have
\[
\nabla \psi_Z(X) = \nabla f(X) + \rho A^T \left( AX - \frac{1}{\rho} Z - \text{Prox}_{\rho g}(AX - \frac{1}{\rho} Z) \right)
\]
where \( g^* \) is the conjugate operator of \( g \) and defined by \( g^*(x) = \sup_v \{ \langle x, v \rangle - g(v) \} \). By Lemma 3.3, \( \psi_Z(\cdot) \) is retraction smooth over Riemannian manifold \( M \), and its Riemannian gradient is
\[
\grad \psi_Z(X) = \text{Proj}_{T_XM}(\nabla \psi_Z(X)).
\]
Thus, at the \( k \)-th iteration, the \( X \)-subproblem is identical to find \( X^{k+1} \) such that
\[
\grad \psi_Z(X) = 0.
\]
Algorithm 1 below summarizes the proposed manifold inexact augmented Lagrangian method in details.

Remark 4.1. 1) The proposed method is an ALM-type method. The complexity of \( X \)-subproblem is as same as that of MADMM. However, our method obtains a joint optimal solution which guarantees the convergence, while the MADMM does not.

2) All efficient Riemannian optimization methods are applicable for the \( X \)-subproblem, e.g., Riemannian gradient method, Riemannian Newton method, etc.

3) The proposed method is utilizable for smooth Riemannian optimization problem under set-constrained, in which \( g(X) = \delta_{\Omega}(X) \), the indictor function of constraint set \( \Omega \).

4.3 Riemannian optimization subproblem

The main computational cost of Algorithm 1 is to solve the \( X \)-subproblem. It is a smooth optimization problem on Riemannian manifold. The \( X \)-subproblem could be restated as follows
\[
\min_X \psi(X), \quad \text{s.t. } X \in M.
\]
where \( \psi = \psi_Z \) given by (4.7). It is a retraction smooth function, so problem (4.10) can be solved by some Riemannian gradient methods including Riemannian gradient descent (RGD), Riemannian conjugate gradient (RCG) and Riemannian trust region (RTR) method, etc. In this paper, we adopt a RGD method to problem (4.15), see Algorithm 2 for details.
Algorithm 1 Manifold inexact augmented Lagrangian method for problem (1.1)

1: **Input:** Let $Z_{\text{min}} < Z_{\text{max}}$, $X_0 \in \mathcal{M}$, $Z_0 \in \mathbb{R}^{d \times r}$. Given $\epsilon_{\text{min}} \geq 0$, $\epsilon_0 > 0$, $\rho_0 > 1$, $\sigma > 1$, $0 < \tau < 1$.

2: **for** $k = 0, 1, \cdots$ **do**

3: Produce the next iterate $(X^{k+1}, Y^{k+1})$: get $X^{k+1}$ by solving problem 

$$
\min_{X \in \mathcal{M}} \psi(Z_k)(X)
$$

inexactly with a tolerance $\epsilon_k$ where $\{\epsilon_k\}_{k \in \mathbb{N}} \downarrow 0$; let $Y^{k+1} = \text{Prox}_{g/\rho_k}(AX^{k+1} - Z_k)$.

4: Update Lagrangian multiplier $Z^{k+1}$ by

$$
Z^{k+1} = Z_k - \rho_k(AX^{k+1} - Y^{k+1})
$$

5: Project $Z^{k+1}$ onto $\{Z : Z_{\text{min}} \leq Z \leq Z_{\text{max}}\}$ to get $\bar{Z}^{k+1}$.

6: Update penalty parameter by

$$
\rho_{k+1} = \begin{cases} 
\rho_k, & \text{if } \|AX^{k+1} - Y^{k+1}\|_\infty \leq \tau\|AX^k - Y^k\|_\infty \\
\sigma \rho_k, & \text{otherwise} 
\end{cases}
$$

7: **end for**

5 Convergence analysis

For convenience of notation, we rewrite problem (4.1) to a standard constraint optimization problem on manifold. Let $W = [X; Y] \in \mathbb{R}^{(n + d) \times r}$, and $\mathcal{N} = \mathcal{M} \times \mathbb{R}^{d \times r}$ be a product manifold.

Then, problem (4.1) can be rewritten to

$$
\min_{W} \theta(W), \text{ s.t. } h(W) = 0, \ W \in \mathcal{N}.
$$

where $\theta(W) = f(X) + g(Y)$, and $h(W) = [A, -I]W \in \mathbb{R}^{d \times r}$. The partial augmented Lagrangian function associated to problem (5.1) is

$$
\mathcal{L}_\rho(W; Z) = \theta(W) + \sum_{i=1}^{d} \sum_{j=1}^{r} Z_{ij}[h(W)]_{ij} + \frac{\rho}{2} \sum_{i=1}^{d} \sum_{j=1}^{r} [h(W)]_{ij}^2
$$

The KKT conditions of problem (5.1) are given by

$$
0 \in \partial \theta(W^*) + \sum_{i=1}^{d} \sum_{j=1}^{r} Z_{ij}^* \text{grad}[h(W^*)]_{ij}, \quad h(W^*) = 0, \ W^* \in \mathcal{N},
$$
Algorithm 2 Riemannian gradient method for subproblem \[4.15\]

1: **Given:** \(X^0 \in \mathcal{M}\), tolerance \(\epsilon > 0\). Let \(\eta^0 = -\nabla \psi(X^0)\).

2: **Initialize:** \(k = 0\).

3: **while** \(\|\eta^k\| \geq \epsilon\) **do**

4: Pick \(\eta^k = -\nabla \psi(X^k)\) and a step size \(\alpha_k\), compute

\[
X^{k+1} = R_{X^k}(\alpha_k \eta^k).
\] (4.16)

5: **end while**

where \(\partial \theta(W^*)\) is Riemannian subdifferential of \(\theta\) at \(W^*\). The KKT system \[5.3\] is identical to \[4.3\] because of that \(\mathcal{M}\) is a Riemannian submanifold embedded in Euclidean space. Inspired by Zhang, Yang and Song [35], the constraint qualifications of problem \[5.1\] is given by:

**Definition 5.1 (LICQ).** Linear independence constraint qualifications (LICQ) are said to hold at \(W^* \in \mathcal{N}\) for problem \[5.1\] if

\[
\{\nabla h(W^*)_{ij} | i = 1, \cdots, d; j = 1, \cdots, r\}
\]

are linearly independent in \(T_{W^*}\mathcal{N}\).

We will analyze the convergence of Algorithm 1 in the following two cases:

1) The iterate \((X^{k+1}, Y^{k+1})\) is an \(\epsilon_k\)-stationary point of iteration subproblem, i.e.,

\[
\|\nabla \psi(Z^k)\| \leq \epsilon_k.
\] (5.4)

2) The iterate \((X^{k+1}, Y^{k+1})\) is an \(\epsilon_k\)-global minimizer of iteration subproblem, i.e.,

\[
\mathcal{L}_{\rho_k}(W^{k+1}; \bar{Z}^k) \leq \mathcal{L}_{\rho_k}(W; \bar{Z}^k) + \epsilon_k, \forall W \in \mathcal{N}.
\] (5.5)

**Remark 5.1.** In the case 1), \[5.4\] is indeed to find \(W^{k+1}\) such that

\[
\delta^k \in \partial \mathcal{L}_{\rho_k}(W^{k+1}; \bar{Z}^k), \|\delta^k\| \leq \epsilon_k.
\]

**Theorem 5.1.** Suppose \(\{W^k\}_{k \in \mathbb{N}}\) is a sequence generated by Algorithm 1. Assumption \[4.1\] and \[5.4\] hold. Then, sequence \(\{W^k\}_{k \in \mathbb{N}}\) has at least one cluster point. Furthermore, if \(W^*\) is a cluster point, and LICQ holds at \(W^*\), then \(W^*\) is a KKT point of problem \[5.1\].

**Proof.** To prove the first part of Theorem 5.1, we need to show that sequence \(\{W^k\}_{k \in \mathbb{N}}\) is bounded. By Assumption \[4.1\], \(\mathcal{M}\) is a compact manifold, hence \(\{X^k\}\) is bounded.

\[
Y^{k+1} = \text{Prox}_{g/\rho}(AX^{k+1} - \frac{1}{\rho} \bar{Z}^k),
\]
there exists $\nu^k \in \partial g(Y^{k+1})$ such that

$$0 = \nu^k - \rho_k (AX^{k+1} - \frac{1}{\rho} \bar{Z}^k - Y^{k+1}).$$

Again by Assumption 4.1, $\partial g(Y^{k+1})$ is bounded, and hence $\nu^k$ is also bounded. It is obvious that $\bar{Z}^k \in [Z_{\min}, Z_{\max}]$ is bounded. Since sequence $\{\rho_k\}_{k \in \mathbb{N}}$ is nondecreasing, we have $\rho_k \geq \rho_0 \ (\forall k \in \mathbb{N})$. Hence $\{Y^k\}_{k \in \mathbb{N}}$ is bounded. In summary, sequence $\{W^k\}_{k \in \mathbb{N}}$ is bounded.

Next, we will show that $W^*$ is a feasible point of (5.1). By the updating rule of $W$ in Algorithm 1, we have $W^k \in \mathcal{N}$.

If $\{\rho_k\}_{k \in \mathbb{N}}$ is bounded, by the updating rule of $\rho_k$, there exists a $k_0 \in \mathbb{N}$ such that

$$\|h(W^k)\|_{\infty} \leq \tau \|h(W^{k-1})\|_{\infty}, \ \forall k \geq k_0,$$

where $\tau \in (0, 1)$. Hence, $h(W^*) = 0$.

If $\{\rho_k\}$ is unbounded, by Remark 5.1 we have

$$\delta^k \in \partial L_{\rho_k}(W^{k+1}; \bar{Z}^k), \ \|\delta^k\| \leq \epsilon_k,$$

where $\epsilon_k \downarrow 0$ as $k \to \infty$. Thus there exists $U^k \in \partial \theta(W^k)$ such that

$$U^k + \sum_{i=1}^d \sum_{j=1}^r (\bar{Z}_{ij}/\rho_k + [h(W^k)]_{ij}) \text{grad}[h(W^k)]_{ij} = \delta^k. \quad (5.6)$$

Dividing both sides of (5.6) by $\rho_k$, we have

$$\sum_{i=1}^d \sum_{j=1}^r (\bar{Z}_{ij}/\rho_k + [h(W^k)]_{ij}) \text{grad}[h(W^k)]_{ij} = (\delta^k - U^k)/\rho_k \quad (5.7)$$

where $\{\bar{Z}^k\}$ is bounded, and $\delta^k \downarrow 0$. Since $\theta(W) = f(X) + g(Y)$, where $g$ is a convex function on $E$, and

$$\partial \theta(W) = \begin{pmatrix} \text{grad} f(X) \\ \partial g(Y) \end{pmatrix},$$

where $\partial g(Y)$ is a subdifferential (set) in usual sense. Invoked by Proposition B.24(b) in [7], the set $\bigcup_{k \in \mathcal{K}} \partial g(Y^k)$ is bounded because that $\{Y^k\}_{k \in \mathcal{K}}$ is a bounded set. In addition, $f(X)$ is a retraction smooth function, hence the Riemannian gradient sequence $\{\text{grad} f(X^k)\}_{k \in \mathcal{K}}$ is bounded. Thus, we have that $\bigcup_{k \in \mathcal{K}} \partial \theta(W^k)$ is bounded. This means that $\{U^k\}$ is bounded.

Taking limits as $k \in \mathcal{K}$ going to infinity on both sides of (5.6), and using the continuity and differentiability of $h$, we have,

$$\sum_{i=1}^d \sum_{j=1}^r ([h(W^*)]_{ij}) \text{grad}[h(W^*)]_{ij} = 0 \quad (5.8)$$
Note that LICQ holds at $W^*$, we conclude that $[h(W^*)]_{ij} = 0$ for all $i, j$.

Since $\{U^k\}_{k \in K}$ is bounded, there exists a subsequence $K_1 \subset K$ such that $\lim_{k \to \infty, k \in K_1} U^k = U^*$. Recall that $\lim_{k \to \infty, k \in K_1} W^k = W^*$. We get $U^* \in \partial \theta(W^*)$ by the closedness property of the limiting subdifferential. Together with $Z_{ij}^{k+1} = Z^k + \rho_k[h(W^k)]_{ij}$ for all $i, j$, one can get from Algorithm 1 that, for all $k \in K_1$,

$$U^k + \sum_{i=1}^{d} \sum_{j=1}^{r} (Z_{ij}^{k+1}) \text{grad}[h(W^k)]_{ij} = \delta^k$$

(5.9)

where $\delta^k$ satisfying $\|\delta^k\| \leq \varepsilon^k$, and $U^k \in \partial \theta(W^k)$.

We claim that $\{Z^k\}$ is bounded. Otherwise, assume $\{Z^k\}$ is unbounded, we have

$$\frac{U^k}{\|Z^{k+1}\|_\infty} + \sum_{i=1}^{d} \sum_{j=1}^{r} \left( \frac{Z_{ij}^{k+1}}{\|Z^{k+1}\|_\infty} \right) \text{grad}[h(W^k)]_{ij} = \frac{\delta^k}{\|Z^{k+1}\|_\infty}$$

Since $\frac{Z^{k+1}}{\|Z^{k+1}\|_\infty} \in [-1, 1]$ is bounded, there exists a subsequence $K_2 \subset K_1$ such that $\lim_{k \to \infty, k \in K_2} \frac{Z^{k+1}}{\|Z^{k+1}\|_\infty} = \bar{Z}$, where $\bar{Z}$ is a nonzero matrix. Taking the limit on $k \in K_2$ going to infinity, we obtain

$$\sum_{i=1}^{d} \sum_{j=1}^{r} \bar{Z}_{ij} \text{grad}[h(W^*)]_{ij} = 0,$$

(5.10)

which contradicts the LICQ condition at $W^*$.

Since $\{U^k\}$ is bounded and $\{\delta^k\} \downarrow 0$, there exists a subsequence $K_3 \subset K_2$ such that $\lim_{k \to \infty, k \in K_3} U^k = U^*$ and $\lim_{k \to \infty, k \in K_3} Z^k = Z^*$. By the continuity of mapping $\text{grad} h$, and taking limits on $k \in K_3$ going to infinity on both sides of (5.9), we have

$$U^* + \sum_{i=1}^{d} \sum_{j=1}^{r} (Z_{ij}^*) \text{grad}[h(W^*)]_{ij} = 0.$$

(5.11)

\[ \square \]

**Lemma 5.1.** Suppose that $W \in \mathcal{N} = M \times \mathbb{R}^{d \times r}$, and $M$ is a stiefel manifold denoted by $\text{St}(n, r)$. Then the LICQ always holds at $\forall W \in \mathcal{N}$.

**Proof.** Let $e_i \in \mathbb{R}^d$ be a $m$-dimensional coordinate vector in which the $i$-th entry is 1 and 0 for others, and $\bar{e}_j \in \mathbb{R}^r$ be a $r$-dimensional coordinate vector. Then

$$\nabla[h(W)]_{ij} = \begin{pmatrix} A^T e_i \bar{e}_j^T \\ -e_i \bar{e}_j^T \end{pmatrix}, \quad i = 1, \ldots, d; j = 1, \ldots, r.$$
A basis of the normal cone of $St(n,r)$ at $X$, denoted by $N_{X}St(n,r)$, is given by
\[
\{X(\bar{e}_{i}\bar{e}_{j}^{T} + \bar{e}_{j}\bar{e}_{i}^{T}) : i = 1, \cdots, r, j = 1, \cdots, r\}.
\]

It is easy to show that, for $\forall W \in \mathcal{N}$, all the vectors in the set
\[
\left\{ \begin{pmatrix} A^{T}e_{i}\bar{e}_{j}^{T} \\ -e_{i}\bar{e}_{j}^{T} \end{pmatrix}, i = 1, \cdots, d; j = 1, \cdots, r. \right\} \cup \left\{ \begin{pmatrix} X(\bar{e}_{i}\bar{e}_{j}^{T} + \bar{e}_{j}\bar{e}_{i}^{T}) \\ 0 \end{pmatrix}, i = 1, \cdots, r; j = 1, \cdots, r. \right\}
\]
are linearly independent. Hence, if there exists $Z$ such that
\[
\sum_{i=1}^{d} \sum_{j=1}^{r} Z_{ij} \nabla [h(W)]_{ij} \in N_{W}N,
\]
we have $Z = 0$. Since $\mathcal{N}$ is a submanifold of Euclidean space, it derives immediately that
\[
\sum_{i=1}^{d} \sum_{j=1}^{r} Z_{ij} \text{grad}[h(W)]_{ij} = 0,
\]
holds if and only if $Z = 0$. Which implies LICQ holds at $W$ and completes the proof.

Next, we consider the case that a $\epsilon_{k}$-global minimizer of the iteration subproblem could be obtained at each iteration of Algorithm 1.

**Theorem 5.2.** Assume that $\{W^{k}\}_{k \in \mathbb{N}}$ is a sequence generated by Algorithm 1. Assumption 4.2 holds, and (5.3) is satisfied at each iteration of Algorithm 1. Let $W^{*}$ be a limit point of $\{W^{k}\}_{k \in \mathbb{N}}$. Then we have
\[
\sum_{i=1}^{d} \sum_{j=1}^{r} [h(W^{*})]_{ij}^{2} \leq \sum_{i=1}^{d} \sum_{j=1}^{r} [h(W)]_{ij}^{2}, \quad \forall W \in \mathcal{N}.
\]

**Proof.** Consider the following two cases: $\{\rho_{k}\}$ bounded and $\rho_{k} \to \infty$.

If $\{\rho_{k}\}$ is bounded, then there exists $k_{0}$ such that $\rho_{k} = \rho_{k_{0}}$ for all $k \geq k_{0}$. Hence
\[
\sum_{i=1}^{d} \sum_{j=1}^{r} [h(W^{k+1})]_{ij}^{2} \leq \tau \sum_{i=1}^{d} \sum_{j=1}^{r} [h(W^{k})]_{ij}^{2}, \quad i = 1, \cdots, m; j = 1, \cdots, r.
\]
Which implies that $h(W^{k}) \to 0$ as $k \to \infty$. We have $h(W^{*}) = 0$, and (5.13) holds.

Then to the case $\rho_{k} \to \infty$. Since $W^{*}$ is a limit point of $\{W^{k}\}$, there exists a subsequence $\mathcal{K} \subset \mathbb{N}$ such that
\[
\lim_{k \to \infty, k \in \mathcal{K}} W^{k} = W^{*}.
\]
Assume by contradiction there exists $W \in \mathcal{N}$ such that
\[
\sum_{i=1}^{d} \sum_{j=1}^{r} [h(W^{*})]_{ij}^{2} \geq \sum_{i=1}^{d} \sum_{j=1}^{r} [h(W)]_{ij}^{2}.
\]
By the boundedness of \( \{ \bar{Z}^k \} \) and \( \rho_k \to \infty \), there exist \( c > 0 \) and \( k_0 \in \mathbb{N} \) such that, for all \( k \in \mathcal{K} \) and \( k \geq k_0 \) we have

\[
\sum_{i=1}^{d} \sum_{j=1}^{r} ([h(W^{k+1})]_{ij} + \frac{1}{\rho_k} \bar{Z}^k_{ij})^2 \geq \sum_{i=1}^{d} \sum_{j=1}^{r} ([h(W)]_{ij} + \frac{1}{\rho_k} \bar{Z}^k_{ij})^2 + c.
\]

Therefore

\[
\theta(W^{k+1}) + \frac{\rho_k}{2} \sum_{i=1}^{d} \sum_{j=1}^{r} ([h(W^{k+1})]_{ij} + \frac{1}{\rho_k} \bar{Z}^k_{ij})^2 \geq \theta(W) + \frac{\rho_k}{2} \sum_{i=1}^{d} \sum_{j=1}^{r} ([h(W)]_{ij} + \frac{1}{\rho_k} \bar{Z}^k_{ij})^2 + \frac{\rho_k c}{2} + \theta(W^{k+1}) - \theta(W).
\]

Since \( \lim_{k \to \infty, k \in \mathcal{K}} W^k = W^* \), and \( \{ \epsilon_k \} \) is bounded, there exists \( k_1 > k_0 \) such that, for all \( k \in \mathcal{K}, k \geq k_1 \) we have

\[
\frac{\rho_k c}{2} + \theta(W^{k+1}) - \theta(W) > \epsilon_k.
\]

Therefore,

\[
\theta(W^{k+1}) + \frac{\rho_k}{2} \sum_{i=1}^{d} \sum_{j=1}^{r} ([h(W^{k+1})]_{ij} + \frac{1}{\rho_k} \bar{Z}^k_{ij})^2 \geq \theta(W) + \frac{\rho_k}{2} \sum_{i=1}^{d} \sum_{j=1}^{r} ([h(W)]_{ij} + \frac{1}{\rho_k} \bar{Z}^k_{ij})^2 + \epsilon_k.
\]

This contradicts (5.5). We have (5.13) and complete the proof. \( \square \)

**Theorem 5.3.** In Algorithm 4, let \( \epsilon_{\min} = 0 \) and \( W^* \) be a limit point of sequence \( \{ W^k \}_{k \in \mathbb{N}} \).

If iterate \( W^{k+1} \) is an \( \epsilon_k \)-global minimizer satisfying (5.5), then \( W^* \) is a global minimizer of problem (1.1). Meanwhile, \( X^* \) is a global minimizer of problem (1.1).

**Proof.** By (5.5), we have

\[
\theta(W^{k+1}) + \frac{\rho_k}{2} \sum_{i=1}^{d} \sum_{j=1}^{r} ([h(W^{k+1})]_{ij} + \frac{1}{\rho_k} \bar{Z}^k_{ij})^2 \leq \theta(W) + \frac{\rho_k}{2} \sum_{i=1}^{d} \sum_{j=1}^{r} ([h(W)]_{ij} + \frac{1}{\rho_k} \bar{Z}^k_{ij})^2 + \epsilon_k
\]

for all \( W \in \mathcal{N} \). Since \( h(W) = 0 \), we get

\[
\theta(W^{k+1}) + \frac{\rho_k}{2} \sum_{i=1}^{d} \sum_{j=1}^{r} ([h(W^{k+1})]_{ij} + \frac{1}{\rho_k} \bar{Z}^k_{ij})^2 \leq \theta(W) + \frac{\rho_k}{2} \sum_{i=1}^{d} \sum_{j=1}^{r} \left( \frac{1}{\rho_k} \bar{Z}^k_{ij} \right)^2 + \epsilon_k.
\]

Which implies that

\[
\theta(W^{k+1}) \leq \theta(W) + \frac{\rho_k}{2} \sum_{i=1}^{d} \sum_{j=1}^{r} \left( \frac{1}{\rho_k} \bar{Z}^k_{ij} \right)^2 + \epsilon_k. \tag{5.14}
\]
If \( \rho_k \to \infty \), by taking limits on both sides of (5.14) as \( k \in K, k \to \infty \), and using \( \lim_{k \to \infty, k \in K} \epsilon_k = 0 \), we get

\[
\theta(W^*) \leq \theta(W), \ \forall \ W \in \mathcal{N}.
\]

In case of that \( \{\rho_k\} \) is bounded, there exists \( k_0 \in \mathbb{N} \) such that \( \rho_k = \rho_{k_0} \) for all \( k > k_0 \). By (5.15) we have

\[
\theta(W^{k+1}) + \frac{\rho_{k_0}}{2} \sum_{i=1}^{d} \sum_{j=1}^{r} ([h(W^{k+1})]_{ij} + \frac{1}{\rho_{k_0}} \bar{Z}_{ij}^{k})^2 \leq \theta(W) + \frac{\rho_{k_0}}{2} \sum_{i=1}^{d} \sum_{j=1}^{r} ([h(W)]_{ij} + \frac{1}{\rho_{k_0}} \bar{Z}_{ij}^{k})^2 + \epsilon_k
\]

for \( W \in \mathcal{N} \). Since \( h(W) = 0 \), we get

\[
\theta(W^{k+1}) + \frac{\rho_{k_0}}{2} \sum_{i=1}^{d} \sum_{j=1}^{r} ([h(W^{k+1})]_{ij} + \frac{1}{\rho_{k_0}} \bar{Z}_{ij}^{k})^2 \leq \theta(W) + \frac{\rho_{k_0}}{2} \sum_{i=1}^{d} \sum_{j=1}^{r} (\frac{1}{\rho_{k_0}} \bar{Z}_{ij}^{k})^2 + \epsilon_k
\]

for all \( k \geq k_0 \). Let \( K_1 \subset K \) and

\[
\lim_{k \to \infty, k \in K_1} \bar{Z}^{k} = Z^*.
\]

Taking limits on both sides of (5.15) as \( k \to \infty, k \in K_1 \), and noting that \( h(W^*) = 0 \), we get

\[
\theta(W^*) + \frac{\rho_{k_0}}{2} \sum_{i=1}^{d} \sum_{j=1}^{r} (\frac{1}{\rho_{k_0}} Z_{ij}^*)^2 \leq \theta(W) + \frac{\rho_{k_0}}{2} \sum_{i=1}^{d} \sum_{j=1}^{r} (\frac{1}{\rho_{k_0}} Z_{ij}^*)^2.
\]

Hence

\[
\theta(W^*) \leq \theta(W), \ \forall \ W \in \mathcal{N},
\]

and the proof is completed. \( \Box \)

6 Experiments

Numerical experiments for testing the performance of the proposed MIALM method, with compared to some existing methods including SOC [30], PAMAL [22], MADMM [29] and ManPG [14], are presented in the current section. All the methods are used to solve the compressed modes and sparse PCA problem. In the MIALM and MADMM, the Riemannian manifold optimization subproblem is handled by “Manopt”, a Matlab toolbox for optimization on manifolds [11]. In the SOC, PAMAL and ManPG methods, the code provided by Chen [14] are used (all codes are available in online). All experiments are run on a personal computer with 4.0GHz Intel Core i7 CPU and 16 GB RAM.
6.1 Compressed modes in Physics

In physics, the compressed modes problem (CMs) seeks spatially localized solutions of the independent-particle Schrödinger equation:

$$\hat{H} \phi(x) = \lambda \phi(x), \quad x \in \Omega,$$

(6.1)

where $\hat{H} = -\frac{1}{2} \Delta$ and $\Delta$ is a Laplacian operator. Consider the 1D free-electron (FE) model with $\hat{H} = -\frac{1}{2} \partial_x^2$. By a proper discretization, the compressed modes problem can be reformulated to

$$\begin{cases}
\min_{X \in \mathbb{R}^{n \times k}} & tr(X^T H X) + \mu \|X\|_1, \\
\text{s.t.} & X^T X = I_d,
\end{cases}$$

(6.2)

where $H$ is the discretized Schrödinger operator, $\mu$ is a regularization parameter. The interesting readers are referred to [33] for more details. For problem (6.2), both SOC and PAMAL consider the identical form as follows:

$$\begin{cases}
\min_{\Psi, Q, P \in \mathbb{R}^{n \times r}} & tr(X^T H X) + \mu \|Q\|_1, \\
\text{s.t.} & Q = X, P = X, P^T P = I_r.
\end{cases}$$

(6.3)

The MADMM handles the separable reformulation of the form

$$\begin{cases}
\min_{\Psi, Q \in \mathbb{R}^{n \times r}} & tr(X^T H X) + \mu \|Q\|_1, \\
\text{s.t.} & Q = X, X^T X = I_r.
\end{cases}$$

(6.4)

In our experiments, the domain $\Omega := [0, 50]$ is discretized with $n$ equally spaced nodes. The parameters of our MIALM are set to: $\tau = 0.99, \sigma = 1.05, \rho_0 = \lambda_{\text{max}}(H)/2, Z_{\text{min}} = -100 \cdot 1_{d \times r}, Z_{\text{max}} = 100 \cdot 1_{d \times r}, Z^0 = 0_{d \times r}$ and $\epsilon_k = \max(10^{-5}, 0.9^k)$, where $k \in \mathbb{N}$ is the iteration counter. We terminated MIALM if $\|X^k - Y^k\|_F^2 \leq 10^{-9}$ or $k \geq 500$. The qr retraction is used in inner iteration of the MIALM, and a Barzilai-Borwein stepsize is used to accelerate it. The inner iteration is terminated if $\|\text{grad}\Psi_{Z_k}(X)\|_X \leq \epsilon_k$ or the iteration number exceeds 20. The final objective value obtained by the MIALM method is denoted by $F_M$.

For the MADMM, the penalty parameter is set to $\rho = \lambda_{\text{max}}(H)/2$. We terminated MADMM if $\|X^k - Y^k\|_F^2 \leq 10^{-9}$ or $F(X^k) \leq F_M + 10^{-7}$, or $k \geq 500$. The inner iteration of the MADMM terminates if the norm of Riemannian gradient of $X$-subproblem is less than $10^{-5}$ or the inner iteration number exceeds 20. For the SOC, PAMAL and ManPG, the parameters are set as same as in [14], except that the penalty parameter $\rho = 2\lambda_{\text{max}}(H)$ in SOC and PAMAL. The ManPG terminates if stopping criterion described in [14] is met or $F(X^k) \leq F_M + 10^{-7}$. For easy comparisons, Table 1 lists the objective function value, sparsity of solution and cpu time. One can find from Table 1 that, our MILAM method outperforms to the other methods.
| $\mu$ | MIALM | ManPG | MADMM |
|------|-------|-------|-------|
|      | time  | $F_M$ | sp    | time  | $F$  | sp    | time  | $F$  | sp    |
| 0.1  | 0.021 | 0.943 | 0.835 | 0.036 | 0.943 | 0.836 | 0.112 | 0.943 | 0.836 |

6.2 Sparse principle component analysis

Given a data set \( \{ b_1, \cdots, b_m \} \) where \( b_i \in \mathbb{R}^{n \times 1} \). The sparse PCA problem is

\[
\begin{aligned}
& \min_{X \in \mathbb{R}^{n \times r}} \sum_{i=1}^{m} \| b_i - XX^T b_i \|_2^2 + \mu \| X \|_1, \\
& \text{s.t. } X^T X = I_r,
\end{aligned}
\]

(6.5)

where \( \mu \) is a regularization parameter. Let \( B = [b_1, \cdots, b_m]^T \in \mathbb{R}^{m \times n} \), problem (6.5) has the form:

\[
\begin{aligned}
& \min_{X \in \mathbb{R}^{n \times r}} - tr(X^T B^T B X) + \mu \| X \|_1, \\
& \text{s.t. } X^T X = I_r.
\end{aligned}
\]

(6.6)

In our experiments, the random data matrix \( B \in \mathbb{R}^{m \times n} \) is generated by MATLAB function \( \text{randn}(m,n) \), in which the entries of \( B \) follow the standard Gaussian distribution. We shift the columns of \( B \) such that they have mean 0, and finally the column-vectors are normalized. The parameters of our MIALM are set as same as that of used for the CMs problem, except that the stopping criterion is modified to \( \| X^k - Y^k \|_F^2 \leq 10^{-8} \) and the penalty parameter \( \rho_0 = \lambda_{\text{max}}^2(B^T B)/2 \). Similarly, the parameters of the MADMM are also set as the same as that used for the CMs problem, except that the penalty parameter \( \rho_0 = \lambda_{\text{max}}^2(B^T B)/2 \). For the SOC, PAMAL and ManPG methods, the stopping criterion and parameter settings provided in [14] are copied. The interesting readers are referred to [14] for details. Table 2 lists performance of all methods on the sparse PCA problem for comparisons.

7 Conclusions

We proposed a manifold inexact augmented Lagrangian method for nonsmooth composite minimization problem on Riemannian manifold. At each iteration of the proposed method, we only need to solve a smooth Riemannian manifold minimization subproblem based on the Moreau envelope. The convergence of the proposed method is established under some mild assumptions. Numerical experiments show that, the proposed method is competitive compared to some existing state-of-the-art methods.
