Abstract: In this paper, the influences of relative humidity (RH) and concentration of O₂ on copper corrosion in H₂S-containing LPG (liquid petroleum gas) were studied. The corrosion products obtained in different environments were also analysed by scanning electron microscopy (SEM), energy dispersive spectrometry (EDS), grazing incidence X-ray diffraction (GIXRD), X-ray photoelectron spectroscopy (XPS) and Fourier transform infrared spectroscopy (FTIR). In H₂S-containing LPG, RH has pronounced influence on the corrosion grade of copper. The variation in the critical point (CP) with the RH of LPG is a linear relationship. The presence of O₂ in dry H₂S has limited influence on the corrosion of copper. In the presence of different RHs, the CP always follows a negative exponential function with O₂ concentration. The analysis of different corrosion products implies different corrosion behaviours and mechanisms, which are dependent on the presence or absence of water vapour. The corrosion mechanisms obtained in four different environments were also proposed.

Keywords: copper corrosion; liquefied petroleum gas; H₂S corrosion; SEM; XPS

1. Introduction

Natural gas is widely used in industry and our daily life. As an important existence of natural gas, liquefied petroleum gas (LPG) is more commonly utilized for its accessibility in transportation. In the exploitation and processing of LPG, sulphur removal is inevitable for the sake of alleviating corrosion attack by sulphide existing in produced LPG [1–3]. Various forms of sulphide, such as hydrogen sulphide, mercaptan and carbonyl sulphide, may lead to corrosion of copper components in production and storage facilities. Although the sulphur removal process can eradicate most of the sulphide to some extent, the residual sulphide, in trace amounts, can also be harmful to the corrosion of copper components. Of those common active sulphides, H₂S is the most harmful to copper, even it is presented in low concentration. Although previous studies have revealed the behaviour of H₂S on copper corrosion in LPG, the influence of other environmental factors, such as the presence of O₂ and relative humidity (RH), also contribute to corrosion attack.

Recently, the corrosion behaviour of copper in the presence of various sulphides has been extensively studied [4–7]. Echeverria investigated the copper corrosion in SO₂ through atomic force microscopy (AFM). The results showed that the microscopic topography and roughness of the copper surface changed after several weeks in a polluted atmosphere containing SO₂ [8]. Majtás discovered that low concentrations of H₂S can corrode copper parts, resulting in electrical failure of electronic equipment. Additionally, the adsorbed water can promote corrosion attack [9]. Zhu proved that the corrosion rate of copper in an SO₂ environment first increases and then gradually decreases with exposure time. Conversely, the corrosion rate of copper in H₂S increases slowly at first and then sharply declines [10]. Araban studied the corrosion behaviour of copper in different rural atmospheres. The results showed that corrosion product of Cu₂O formed preferentially, in which
relative humidity and ammonium sulphate had remarkable influence on the corrosion behaviour [11]. Monzó found that sulphide has an obvious influence on corrosion between the boundary and the centre of a copper sheet. Additionally, elemental sulphur is more corrosive than ethanethiol. The corrosion products of elemental sulphur are in the form of nodule particles, and the ethanethiol is in the form of a uniform film [12]. García found that, at low concentrations of elemental sulphur (5 ppm), mercaptans can significantly promote corrosion. At high concentrations of elemental sulphur (25 ppm), mercaptans inhibit the corrosion of elemental sulphur. Disulphide has an obvious inhibition effect on the corrosion of elemental sulphur [13]. Studies on the corrosion behaviour of copper in the outdoor natural atmosphere have also been reported [14–20]. Kong proved that the uneven corrosion of copper in the atmosphere of Turpan is caused by the dry–wet cycle and the cold–heat cycle [21]. Lopesino believed that the corrosion of copper is more serious when closer to the coast, and the degree of patina coverage depends on the concentration of chloride in the atmosphere [22]. Yan confirmed that the corrosion rate of copper in the atmosphere with sodium chloride is almost 30000 times higher than that in the blank atmosphere [23]. Some other studies focused on the influence of RH on the corrosion behaviour of copper [24–26]. Odnevall believed that in the rural atmosphere containing ammonium sulphate, the RH of the gas had a great influence on the corrosion behaviour of copper [12]. Sharma proposed that regarding copper in H$_2$S with low relative humidity, the Cu$_2$O layer resulted by air has a good protective effect on H$_2$S. It almost has no protection under high RH [27]. Wu proved that the RH of the chloride-containing atmosphere is a key factor affecting the corrosion behaviour of copper wires [28]. The corrosion behaviour of chloride on copper has also been extensively studied [29]. Chen proposed that the non-uniform growth of corrosion products on the copper surface in chloride-containing sulphide aqueous solutions resulted in a potential difference between the “thick film” and the “thin film”, and this small potential difference accelerated the occurrence of corrosion [30]. Lu believed that chloride ions in the marine atmosphere of Nansha are the key factors to accelerate the corrosion of copper, and the corrosion products are Cu$_2$O and Cu$_2$Cl(OH)$_3$ [31]. Schindelholz believed that sodium chloride is favourable for the formation of NaOH-rich diffusion regions, and copper preferentially forms Cu$_2$O and Cu(OH)$_2$ [32]. There are also few reports on the electrochemical study of corrosion products on copper surfaces [33]. Tran found that the growth of corrosion product films of copper exposed to H$_2$S-containing subsurface gas has three successive stages: the first stage is a linear growth rate in thin layers (less than 15 nm). In the second stage, the oxidation rate is limited by the diffusion of copper(I) ions through the thicker corrosion layer. The third stage is linear growth [34]. Fiaud believes that both hydrogen sulphide concentration and relative humidity can promote the growth of oxide and sulphide corrosive substances. The growth mechanism of Cu$_2$O is an electrochemical mechanism, and the growth mechanism of Cu$_2$S is a mixed chemical and electrochemical mechanism [35]. Some other reports aimed at the corrosion behaviour of copper regarding other aspects, for example, application of theoretical calculations to copper corrosion [5–7,24], the influence of various organic acids on copper corrosion [36,37], the influence of changes in magnetic field on copper corrosion [38] and corrosion behaviour of copper by oxygen plasma [39].

Although some behaviours of copper corrosion in H$_2$S have been studied, there is still some insufficiency. It is necessary to investigate the corrosion behaviour and mechanism of copper in LPG containing H$_2$S at different conditions, including the presence of different RHs and O$_2$ concentrations. In this paper, the influence of RH and O$_2$ on the corrosion behaviour of copper in H$_2$S-containing LPG was studied, the corrosion products on the surface of copper sheets were characterized and analysed and the corresponding corrosion mechanism of H$_2$S on copper was proposed.
2. Experimental Methods

2.1. Materials

Copper sheets used in corrosion experiments were purchased from Fushun Keruisi Instrument Co., Ltd. Fushun Liaoning Province, China, which strictly follows the requirement of the ASTM standard [40]. The size of cuboid copper sheet is 75 mm × 12.5 mm × 3 mm, with the purity higher than 99.9%. Copper powder (analytical grade, Chengdu Kelon Chemical Co., Ltd. Chengdu, China) was used in X-ray photoelectron spectroscopy (XPS) and FTIR (Fourier transform infrared spectrometry). The purity of powder is 99.5% and the average particle size is 23 µm. The components of LPG are listed in Table 1. H₂S and O₂ gas used in the experiments were purchased from Zhengrong Gas company (Chengdu, China). The purity of H₂S and O₂ is 99.9%.

Table 1. The components of LPG.

| Component | wt./% |
|-----------|-------|
| Propane   | 70    |
| Isobutane | 14    |
| N-Butane  | 16    |

2.2. Copper Corrosion Tests

Copper corrosion tests were carried out according to the ASTM standard [40]. The copper sheet was first abraded with 65 µm silicon carbide sandpaper. Then, it was washed with isooctane. The copper surface was polished by 105 µm silicon carbide particles, which were operated with the assistance of isooctane-soaked degreasing cotton. The prepared copper sheets were suspended into the cylinder (the special closed container for corrosion test) in three parallel experiments. Then, high-purity N₂ was used to remove the air inside the cylinder by ventilating N₂ into the cylinder to substitute the air. Then, to control the mass flow of LPG and H₂S through a flowmeter (FMA5400A, Omega, San Antonio, TX, USA), they were injected into the cylinder and the gas was mixed evenly. Subsequently, the valve was fastened. Finally, the cylinder with mixture of LPG and H₂S was vertically immersed in a water bath at a constant temperature (40 ± 0.5 °C) for 60 ± 5 min. After the experiment time was over, the liquid and gas in the cylinder were discharged. The copper sheets were taken out and compared with the standard colour plate [40]. Next, the corrosion grades of the copper sheets were evaluated. The details of the grade evaluation are shown in Table 2. The standard stipulates that if the corrosion level of a copper sheet reaches 2a and above, it is regarded as unqualified in corrosion.

Table 2. The grading table of copper corrosion standard swatches [40].

| Corrosion Level | Copper Colour | Detailed Description |
|-----------------|---------------|----------------------|
| 1               | mild discolouration | a. pale orange, almost the same as freshly polished copper  
|                 |                | b. dark orange      
|                 |                | a. fuchsia          
|                 |                | b. lavender         |
| 2               | moderate discolouration | c. multicoloured with lavender blue, silver or both, overlaid on fuchsia  
|                 |                | d. silver           
|                 |                | e. brass or golden yellow |
| 3               | deep discolouration | a. multicolour magenta overlay brass |
| 4               | corrosion      | b. multicolour (malachite green) shown by red and green, no grey  
|                 |                | a. transparent black, dark grey or brown with only malachite green  
|                 |                | b. graphite or matte black  
|                 |                | c. glossy black or jet-black glossy black |

2.3. Analysis of Corrosion Products

To facilitate the characterization of corrosion products, the concentrations of H₂S and O₂ were increased to 50 ppm and 10 ppm in copper corrosion tests. The copper sheets were used in corrosion tests for characterizations such as scanning electron microscopy (SEM),
energy dispersive spectrometry (EDS) and grazing incidence X-ray diffraction (GIXRD). Samples of corrosion products for XPS and FTIR were prepared with powder, which could provide better results than copper sheets. The copper powder samples were applied by placing 0.1 g of copper powder in a glass sample bottle. Then, the glass sample bottle was suspended in a cylinder to conduct a copper corrosion experiment.

SEM (Model EVO MA15, ZEISS, Jena, Germany) was used to observe the morphology of the corrosion products on the copper surface. EDS (Model X-MaxN, OXFORD INSTRUMENTS Company, Abingdon, UK) was used to analyse the elemental composition of the corrosion products on the copper sheet surface. XPS (Nexsa type, Thermo Scientific, Waltham, MA, USA) was used to analyse the elemental composition and valence distribution of the corrosion products on the copper powder surface. The original XPS image was fitted with Casa XPS software. GIXRD (SmartLab 9 kw, Rigaku, Tokyo, Japan) was used to analyse the phase composition of corrosion products on the copper sheet surface. The original XPS image was fitted with Casa XPS software. GIXRD (SmartLab 9 kw, Rigaku, Tokyo, Japan) was used to analyse the phase composition of corrosion products on the copper sheet surface.

3. Results and Discussion

3.1. Influence of Humidity on Copper Corrosion in H₂S-Containing LPG

The corrosion behaviour of copper in H₂S-containing LPG is very sensitive to the gas humidity. The higher the gas humidity, the more easily copper is corroded by H₂S. Figure 1a shows the variation in the corrosion grade of copper in H₂S-containing LPG at different gas humidities. In LPG containing 3 ppm H₂S, the corrosion grade of copper gradually intensifies with the increase in gas humidity. At 0–30% RH, there is no significant corrosion on the copper surface (corrosion grade is 1a). At 50–100% RH, the surface of the copper sheet begins to corrode (at 50% RH, the copper corrosion grade is 2a). The degree of corrosion varies with humidity. The copper corrosion grade reaches 2e at 100% RH. Meanwhile, the variation in the copper corrosion grade in LPG without H₂S in the presence of different gas humidities is used as comparison, in which the copper surface does not corrode at all humidities (corrosion grade is 1a).

![Figure 1. (a) Variation in copper corrosion grade in H₂S-containing LPG with humidity; (b) the influence of H₂S concentration and RH on the corrosion grade of copper in LPG.](image)

The critical point (CP) of copper corrosion in H₂S-containing LPG decreases with the increase in the relative humidity of LPG. The CP is defined as the lowest H₂S concentration to reach the corrosion grade of 2a at specific environmental conditions. Figure 1b shows the influence of H₂S concentration and RH on the corrosion grade of copper in LPG. It can be seen that the CP gradually decreases with the increase in gas humidity. From 0% RH to 100% RH, the CP decreases from 3.8 ppm H₂S to 1.7 ppm H₂S. It indicates that higher humidity is more beneficial to the corrosion process. In higher humidity, the thin film of
water at the copper surface forms more easily, which provides an electrolyte environment for H$_2$S dissolution and electrochemical corrosion. With the increase in RH, the thickness of the water film at the interface increases, which will provide a better condition for electrochemical corrosion. Therefore, the corrosion attack is more severe at higher RH and the CP would be lowered with the increase in RH.

The influence of RH on the CP is shown in Figure 2. The results of the CP at different RHs show a linear relationship. The fitted data obey Equation (1) as follows:

$$ CP = -0.021 \times RH + 3.77 , \quad R_0 = 0.96 $$

(1)

where CP is the critical point of copper corrosion, corresponding to the lowest H$_2$S concentration for reaching the corrosion grade of 2a. RH is the relative humidity for the corrosion test. R is the coefficient of determination. The results imply that with the increase in RH, the thickness of the water film formed at the copper surface increases accordingly. The thicker water film is more favourable for H$_2$S dissolution. Consequently, the electrochemical corrosion process is enhanced.

![Figure 2](image-url)

**Figure 2.** The influence of RH on CP of copper corrosion in H$_2$S-containing LPG.

### 3.2. Synergistic Effect of Oxygen and Humidity on Copper Corrosion in H$_2$S-Containing LPG

A small amount of O$_2$ has limited influence on the corrosion of copper in dry LPG (0% RH). Figure 3a shows the variation in copper corrosion grade with O$_2$ content in LPG (0% RH) containing H$_2$S. As can be seen from Figure 3a, in pure LPG (without H$_2$S), the corrosion grade of copper does not change with the increase in O$_2$ content (corrosion grade is 1a). No apparent corrosion happened at the copper surface at such condition. In LPG containing trace H$_2$S (1 ppm), slight corrosion on the copper surface appears with the increase in O$_2$ content. Among them, there is no apparent corrosion on the copper surface from 0 to 5 ppm O$_2$, and the corrosion grade of copper sheets in 10 ppm O$_2$ begins to rise to 1b, which is also below 2a.
A small amount of O$_2$ has a pronounced effect on the corrosion of copper in wet LPG (100% RH). Figure 3b is the variation in copper corrosion grade in H$_2$S-containing LPG (100% RH) with O$_2$ concentration. It demonstrates that in the absence of H$_2$S, the copper corrosion grade can hardly be changed with the increase in O$_2$ content. The copper surface does not corrode in 0–5 ppm O$_2$, displaying a corrosion grade of 1a. In the presence of 10 ppm O$_2$, the copper corrosion grade is slightly promoted to 1b. In the presence of a trace amount of H$_2$S (1 ppm) at 100% RH, the degree of corrosion is sharply intensified with the increase in O$_2$ content. An amount of 0.5 ppm of O$_2$ can lead to unqualified copper corrosion (grade 2a). When the O$_2$ content increases to 1 ppm, the corrosion grade rapidly climbs to grade 2d. When the content of O$_2$ continues to increase, the corrosion grade is stabilized at grade 2d.

Figure 3 reveals that the coexistence of gas humidity and O$_2$ has a notable synergistic effect on the corrosion of copper in LPG in the presence of H$_2$S. Compared with pure LPG (0% RH, 0 ppm O$_2$), the copper in LPG containing wet H$_2$S and O$_2$ is more easily corroded.

In order to further study the synergistic effect of oxygen and humidity on the CP of copper corrosion in H$_2$S-containing LPG, the corrosion behaviour of copper in H$_2$S-containing LPG in the presence of different oxygen concentrations was studied at 0% RH, 30% RH, 50% RH, 80% RH and 100% RH, respectively. The results are shown in Figure 4. It can be seen that at every RH condition, the CP gradually decreases with the increase in O$_2$ concentration. At the same oxygen concentration, CP gradually declines with the increase in the gas humidity.
Figure 4. Influence of oxygen content on CP at (a) 0% RH, (b) 30% RH, (c) 50% RH, (d) 80% RH, (e) 100% RH.

More precise behaviour can be illustrated by interpreting the relationship between the CP and O$_2$ concentration at different RHs, as is shown in Figure 5. The discussion is carried out at different RHs.

Figure 5. Fitted data of the CP in different LPG environments.
(a) In the absence of water (0% RH), CP follows a linear relationship with O\(_2\) concentration. The fitted data obey Equation (2) as follows:
\[
CP_{0\%} = 3.81 - 0.978 C_0, \quad R_1 = 0.98
\] (2)
where \(CP_{x\%}\) is the critical point of copper corrosion in H\(_2\)S-containing LPG (x% RH), corresponding to the minimum H\(_2\)S concentration for corrosion grade 2a. \(C_0\) is the oxygen concentration of LPG in the copper corrosion test. \(R\) is the coefficient of determination.

(b) In the presence of water (30% RH), CP follows a negative exponential function with the O\(_2\) concentration. The fitted data obey Equation (3) as follows:
\[
CP_{30\%} = 0.720 e^{-3.82 C_0} + 2.585, \quad R_2 = 0.99
\] (3)

(c) In the presence of water (50% RH), CP follows a negative exponential function with the O\(_2\) concentration. The fitted data obey Equation (4) as follows:
\[
CP_{50\%} = 0.720 e^{-3.82 C_0} + 1.685, \quad R_3 = 0.99
\] (4)

(d) In the presence of water (80% RH), CP follows a negative exponential function with the O\(_2\) concentration. The fitted data obey Equation (5) as follows:
\[
CP_{80\%} = 0.793 e^{-4.74 C_0} + 1.305, \quad R_4 = 0.99
\] (5)

(e) In the presence of water (100% RH), CP follows a negative exponential function with the O\(_2\) concentration. The fitted data obey Equation (6) as follows:
\[
CP_{100\%} = 1.123 e^{-10.20 C_0} + 0.564, \quad R_5 = 0.98
\] (6)

In the absence of H\(_2\)O, the contribution of O\(_2\) to copper corrosion is relatively even, which is consistent with a previous report [27]. However, the presence of H\(_2\)O makes copper corrosion more sensitive to O\(_2\) even at low O\(_2\) concentration. The formation of a water film on the copper surface makes the corrosion process different. According to the Arrhenius Equation, Equations (7) and (8), in kinetics, when the temperature of the reaction system is constant, the rate constant of a specific chemical reaction is related to the activation energy of the reaction. The lower the activation energy of the reaction, the faster the reaction rate is. In the presence of H\(_2\)O, the activation energy in the reaction system decreases (Equation (9)). Compared with the reaction system without H\(_2\)O, the reaction rate constant \((k)\) is larger, so the reaction rate is faster. This explains why the CP at 0% RH is higher than the CP in the presence of H\(_2\)O.

\[
k_{(0)} = A e^{(-E_{a(0)}/RT)} \quad (7)
\]
\[
k_{(c)} = A e^{(-E_{a(c)}/RT)} \quad (8)
\]
from Equations (7) and (8):
\[
E_{a(c)} = E_{a(0)} - RT \ln \left( k_{(c)}/k_{(0)} \right) \quad (9)
\]
where \(k_{(0)}\) is the rate constant of the reaction, \(k_{(c)}\) is the rate constant of the reaction after adding the catalyst, \(E_{a(0)}\) is the activation energy of the reaction (kJ·mol\(^{-1}\)), \(E_{a(c)}\) is the activation energy of the reaction after adding the catalyst (kJ·mol\(^{-1}\)), \(A\) is the pre-exponential factor, \(e\) is the natural base (2.718), \(R\) is the gas constant (8.314 J·mol\(^{-1}\)·K\(^{-1}\)) and \(T\) is the thermodynamic temperature (K). The presence of the water film, which acts as a catalyst in the system at the interface, changes the kinetics of the corrosion process.
The variation in the CP with O\textsubscript{2} at different RHs can also be explained by Equations (7)–(9). It is well known that the presence of a water film at the interface can reduce the activation of the reaction, which can increase the number of activated molecules in the reaction system by increasing the number of effective collisions. Thus, it significantly accelerates the reaction rate. A higher RH in the reaction system means a thicker water vapour film on the copper surface, which implies greater effectiveness in promoting the corrosion process. When the reaction concentration is constant, the thicker water film can generate more activated molecules in the reaction system, the reaction rate constant \(k\) is larger and more effective collisions are generated per unit time to form more Cu\textsubscript{2}S and Cu\textsubscript{2}O.

3.3. Corrosion Mechanism of Copper in Different H\textsubscript{2}S-Containing LPG Environments

3.3.1. Surface Morphologies after Corrosion

In different environments, LPG with H\textsubscript{2}S, H\textsubscript{2}S + H\textsubscript{2}O, H\textsubscript{2}S + O\textsubscript{2} and H\textsubscript{2}S + O\textsubscript{2} + H\textsubscript{2}O, the microscopic morphologies of the corrosion products on the copper surface sheet are shown in Figure 6. In the absence of H\textsubscript{2}S, the copper surface displays an uncorroded appearance with grooves of abrasion. When corroded in H\textsubscript{2}S-containing LPG, the copper surface is evenly covered with a thick corrosion product film. The corrosion products are in the shape of a regular hexagon with sharp edges and corners. In LPG (100% RH) containing H\textsubscript{2}S + H\textsubscript{2}O, the copper surface is evenly covered with a thick layer of corrosion product film. The corrosion products are spherical and accumulate at the grooves of scratches, indicating that the nucleation and growth of corrosion tend to preferentially happen at grooves of scratches [41]. A similar phenomenon also appears in other environments. In H\textsubscript{2}S + O\textsubscript{2}, the amount of corrosion products is significantly reduced. The corrosion products are sporadically distributed on the copper surface. The white particles of corrosion products are irregular in shape and size. It can be seen from the morphology that the general corrosion at this condition is significantly reduced, which is consistent with the previous experimental results. The corrosion attack happens at localized active sites, not on the whole surface. In H\textsubscript{2}S + H\textsubscript{2}O (100% RH) + O\textsubscript{2}, it exhibits a thick corrosion product film on the copper surface. Some irregular white corrosion products attach on the film surface.

Figure 6. Cont.
3.3.2. EDS Analysis of Corrosion Products

EDS was used to analyse the elemental information of corrosion products. Figure 7 and Table 3 manifest the elemental content of copper corrosion products at four medium conditions (H₂S, H₂S + H₂O, H₂S + O₂ and H₂S + O₂ + H₂O). It can be seen from the results that the corrosion products of LPG in H₂S mainly contain S and Cu, indicating that the corrosion products are only composed of copper sulphides. The corrosion products of LPG containing H₂S + H₂O mainly contain S, Cu and O, implying that they are mainly composed of copper sulphides and oxides. It is also possible that oxides were generated by exposure of the sample to air. The corrosion products in H₂S + O₂ mainly contain S, Cu and O. It shows that the content of S is much higher than that of O, indicating that the corrosion products are mainly composed of a large amount of copper sulphides and a small amount of copper oxides. The corrosion products in H₂S + H₂O + O₂ mainly contain S, Cu and O elements, meaning that the corrosion products are mainly composed of copper oxides and sulphides. The content of O is much higher than that of S, implying that the existence of H₂O and O₂ is more favourable for the growth of copper oxide. In the presence of H₂O (100% RH), it is more favourable to form a water film on the copper surface, which in turn leads to the dissolution and diffusion of oxygen. The electrochemical corrosion happens with the cathode process of oxygen depolarization reaction. Additionally, the dissolution of H₂S in water film leads to the emergence of H⁺. The hydrogen depolarization reaction...
as a cathodic process also happens. The two cathodic processes occur at the same time in \( \text{H}_2\text{S} + \text{O}_2 + \text{H}_2\text{O} \), which induces the synergistic corrosion effects.

![Figure 7. EDS images of corrosion products in different LPG environments.](image)

**Table 3.** The elemental content of corrosion products at four different corrosion conditions.

| Element | \( \text{H}_2\text{S} \) | \( \text{H}_2\text{S} + \text{H}_2\text{O} \) | \( \text{H}_2\text{S} + \text{O}_2 \) | \( \text{H}_2\text{S} + \text{O}_2 + \text{H}_2\text{O} \) |
|---------|----------------------|----------------------|----------------------|----------------------|
| O       | 9.94                 | 2.85                 | 2.85                 | 8.40                 |
| S       | 5.18                 | 8.66                 | 14.98                | 88.09                |
| Cu      | 90.06                | 86.15                | 82.17                | 3.50                 |
| Total   | 100.00               | 100.00               | 100.00               | 100.00               |

3.3.3. GIXRD Analysis of Corrosion Products

In order to further reveal the corrosion mechanism of copper sheets in different LPG environments, GIXRD was used to analyse the corroded copper sheets in the presence of \( \text{H}_2\text{S}, \text{H}_2\text{S} + \text{H}_2\text{O}, \text{H}_2\text{S} + \text{O}_2 \) and \( \text{H}_2\text{S} + \text{H}_2\text{O} + \text{O}_2 \), respectively, and the incident angle of GIXRD was 0.7°. The results in Figure 8 show that the spectrum of corroded copper in \( \text{H}_2\text{S} \)-containing LPG is mainly the diffraction peaks of \( \text{Cu} \) and \( \text{Cu}_2\text{S} \), in which \( \text{Cu}_2\text{S} \) preferentially grows on the (−536) crystal plane. The spectrum of corroded copper in LPG containing \( \text{H}_2\text{S} + \text{H}_2\text{O} \) is mainly the diffraction peaks of \( \text{Cu} \) and \( \text{Cu}_2\text{S} \), in which \( \text{Cu}_2\text{S} \) preferentially grows on the (−232) crystal plane. The expected spectrum of \( \text{Cu}_2\text{O} \) cannot be obtained, which has been proven by EDS. This is due to a too little amount of corrosion products. The spectrum of corrosion products in LPG containing \( \text{H}_2\text{S} + \text{O}_2 \) is similar to the diffraction peaks of corrosion products at \( \text{H}_2\text{S} \) conditions, mainly \( \text{Cu} \) and \( \text{Cu}_2\text{S} \) diffraction peaks. Similarly, \( \text{Cu}_2\text{S} \) grows preferentially on the (−536) crystal plane. The spectrum of corrosion products in LPG containing \( \text{H}_2\text{S} + \text{O}_2 + \text{H}_2\text{O} \) is mainly \( \text{Cu}, \text{Cu}_2\text{S} \) and \( \text{Cu}_2\text{O} \). The diffraction peak of \( \text{Cu}_2\text{O} \) is obviously stronger than that of \( \text{Cu}_2\text{S} \), indicating that
the conditions are more preferable to the growth of Cu$_2$O [34,35,42]. In addition, in this circumstance Cu$_2$S preferentially grows along the (034) crystal plane, which is different from other environmental conditions.

3.3.4. XPS Analysis of Corrosion Products

XPS was also applied to analyse the valence states of corrosion products of copper sheets in different LPG environments, including H$_2$S, H$_2$S + H$_2$O, H$_2$S + O$_2$ and H$_2$S + H$_2$O + O$_2$. The results are shown in Figure 9. Figure 9a is a comparison diagram of the Cu 2p spectrum of the corrosion products in different LPG environments. In the Cu 2p spectrum of the corrosion products in H$_2$S, the peaks at 932.75 eV and 945 eV correspond to the characteristic peak of Cu$_2$S and the satellite peak of Cu$^+$ at the 2p3/2 orbital, respectively. The peaks at 932.77 eV, 934.10 eV and 943.00 eV in Cu 2p spectrum of corrosion products in H$_2$S+H$_2$O correspond to the characteristic peaks of Cu$_2$S, CuO and the satellite peaks of Cu$^{2+}$ at the 2p3/2 orbital, respectively. The peaks at 932.70 eV, 934.27 eV and 943.00 eV in the Cu 2p spectrum of corrosion products in H$_2$S+O$_2$ correspond to the characteristic peaks of Cu$_2$S, CuO and the satellite of Cu$^{2+}$ at the 2p3/2 orbit, respectively. The peaks at 932.80 eV, 932.51 eV and 945.00 eV in the Cu 2p spectrum of the corrosion products with H$_2$S + H$_2$O + O$_2$ correspond to the characteristic peaks of Cu$_2$S, Cu$_2$O and the satellite of Cu$^+$ at the 2p3/2 orbital, respectively, which are consistent with the XRD results. Figure 9b is the analysis result of the high-resolution S 2p spectrum. As seen in Figure 9b, in different LPG environments, the XPS signal of S is weak and exists in the form of Cu$_2$S.
Figure 9c shows the comparative analysis results of the content of Cu$_2$S, Cu$_2$O and CuO in the Cu 2p spectrum in different LPG environments. The detailed information of each phase is shown in Table 4. It can be seen from Figure 9c that Cu$_2$S exists in all four conditions, and the proportion is the highest in pure H$_2$S. With the addition of H$_2$O and O$_2$, the content of Cu$_2$S decreases and the content of CuO increases gradually. In the presence of H$_2$O + O$_2$, Cu$_2$S content begins to rise again, and Cu$_2$O appears in large quantities, which agrees with the previous EDS and XRD results.

Table 4. The content ratio of each phase in the corrosion products in the Cu 2p spectrum.

| Element | Peak Type | Condition | BE (ev) | Area% |
|---------|-----------|-----------|---------|-------|
| CuS     | H$_2$S    | 932.75    | 100.00  |
|         | H$_2$S + H$_2$O | 932.77 | 52.74  |
|         | H$_2$S + O$_2$ | 932.70 | 32.56  |
|         | H$_2$S + H$_2$O + O$_2$ | 932.80 | 70.26  |
| Cu      | H$_2$S    | -         | -       |
|         | H$_2$S + H$_2$O | -   | -      |
|         | H$_2$S + O$_2$ | -   | -      |
|         | H$_2$S + H$_2$O + O$_2$ | 932.51 | 29.74  |
| CuO     | H$_2$S    | -         | -       |
|         | H$_2$S + H$_2$O | 934.10 | 47.26  |
|         | H$_2$S + O$_2$ | 934.27 | 67.44  |
|         | H$_2$S + H$_2$O + O$_2$ | -   | -      |

3.3.5. FTIR Analysis of Corrosion Products

FTIR was used to analyse the corrosion products in different LPG environments. The results are shown in Figure 10. It compares the FTIR spectra of copper powder and copper powder with four different corrosion products. The full FTIR spectra of all corrosion products are similar to the blank. The absorption peak at 3743 cm\(^{-1}\) represents the stretching vibration absorption peak of free-state O-H in the impurities on the copper powder surface. Compared with the blank, the weakening of the peak intensity is caused by the accumulation of a thick layer of corrosion products on the copper powder surface. Compared with blank, the absorption peak of 3446 cm\(^{-1}\) is a composite peak, which is composed of a stretching vibration absorption peak of the associative O-H and Cu(I)-S on the copper powder surface. The phenomenon of increased peak intensity is due to the presence of a large amount of Cu\(_2\)S (3470 cm\(^{-1}\)) after corrosion. The absorption peaks of 2923 cm\(^{-1}\) and 2854 cm\(^{-1}\) represent the stretching vibration absorption peaks of the C-H bond in the methylene group. The phenomenon of peak intensity enhancement is caused by the residual LPG in the corrosion products. In the FTIR spectrum of the bank, there are many unknown absorption peaks around 1500 cm\(^{-1}\), which should be caused by impurities of the copper powder surface. Figure 10b is an FTIR comparison of 920–1230 cm\(^{-1}\). Compared with the blank, the absorption peak at 1160 cm\(^{-1}\) is significantly enhanced, which can be attributed to the stretching vibration of Cu(I)-S (1145 cm\(^{-1}\)). The reason why the peak intensity at this position is similar to the blank can be ascribed to little corrosion products on the copper powder surface in H\(_2\)S + O\(_2\). Compared with the blank, the peak position of 1081 cm\(^{-1}\) appears blue-shifted, which is caused by the vibration of a large amount of Cu(I)-S (1115 cm\(^{-1}\)). This phenomenon is more pronounced in conditions with more corrosion products. Figure 10c shows the FTIR comparison between 400 cm\(^{-1}\) and 800 cm\(^{-1}\) for the four corrosion products and the blank. Compared with the blank, the apparent enhancement of the absorption peak at 713 cm\(^{-1}\) is due to the in-plane rocking vibration of C-H in the methylene group of the residual LPG adsorbed in the corrosion product. As for the weak absorption peak at 619 cm\(^{-1}\) in H\(_2\)S and H\(_2\)S + H\(_2\)O, it can be regarded as the stretching vibration peak of Cu(I)-S (618 cm\(^{-1}\)). In H\(_2\)S + O\(_2\) and H\(_2\)S + H\(_2\)O + O\(_2\), a strong absorption characteristic peak at 619 cm\(^{-1}\) can be regarded as the composite absorption peak of Cu\(_2\)S and Cu\(_2\)O (the absorption peak positions of Cu(I)-S (618 cm\(^{-1}\)) and Cu(I)-O (614 cm\(^{-1}\)) are very similar). The strong absorption peak at 499 cm\(^{-1}\) is due to the stretching vibration of Cu=O [42–45].

![Figure 10](image_url)

**Figure 10.** FTIR images of corrosion products on copper powder in different LPG environments: (a) FTIR full spectrum, (b) FTIR images of 920–1230 cm\(^{-1}\), (c) FTIR images of 445–800 cm\(^{-1}\).

The results of the analysis on the differences in the absorption peaks in the FTIR reveal that Cu\(_2\)S will be formed on the copper surface in the four conditions. The presence of H\(_2\)O promotes the production of CuO.
3.4. Corrosion Mechanism of Copper in Different LPG Environments

Based on the results of copper corrosion tests and corrosion product analysis, the copper corrosion mechanisms of copper at different LPG environments can be proposed as follows.

3.4.1. Corrosion Mechanism in H$_2$S

The corrosion mechanism of copper in LPG only containing H$_2$S is a chemical corrosion process. The corrosion process is carried out according to the reaction Equations (10) and (11). Figure 11 is a schematic diagram of the corrosion steps in H$_2$S-containing LPG. In the first step, H$_2$S gas in the LPG is adsorbed on the copper surface. Then, H$_2$S reacts with Cu atoms at the surface to generate H$_2$ and Cu$_2$S. The whole corrosion process is a chemical process. Electrochemical corrosion cannot occur due to the absence of the electrolyte.

\[
H_2S(g) \rightleftharpoons H_2S(ads) \tag{10}
\]
\[
H_2S(ads) + 2Cu \rightleftharpoons Cu_2S + H_2 \tag{11}
\]

Figure 11. Schematic diagram of corrosion steps of copper sheet in H$_2$S-containing LPG. (a) step1. (b) step2.

3.4.2. Corrosion Mechanism in H$_2$S+H$_2$O

The corrosion mechanism of copper in LPG containing H$_2$S + H$_2$O is an electrochemical corrosion process. The corrosion process is carried out according to the reaction Equations (12)–(16). Figure 12 shows the schematic corrosion steps in LPG with H$_2$S + H$_2$O. The process of electrochemical corrosion can be explained by Figure 12a–c. Firstly, H$_2$O exists in the form of a water film on the copper surface. H$_2$S in LPG dissolves into the water film and further hydrolyses to form a great amount of HS$^-$, H$_3$O$^+$ (hydronium ions) and a small amount of S$^{2-}$. Furthermore, the process of the anodic reaction is losing electrons of a Cu atom to form Cu$_2$S with S$^{2-}$, as expressed in Equation (15). The cathodic reaction can be undertaken as Equation (16), which is the traditional hydrogen depolarization reaction. At this time, the massive consumption of S$^{2-}$ further promotes the dissolution and hydrolysis of H$_2$S in LPG, which continuously accelerates the corrosion of copper and results in a great amount of Cu$_2$S precipitation. However, when the water film is insufficient (low humidity), it is difficult to form an effective electrochemical corrosion environment. In this circumstance, the chemical process may be the main reason for corrosion. This is consistent with the results of XRD, XPS and FTIR. A small amount of CuO in XPS and FTIR is likely due to the contamination of oxidization in air.

\[
H_2S(g) \rightleftharpoons H_2S(l) \tag{12}
\]
\[
H_2S(l) + H_2O \rightleftharpoons HS^- + H_3O^+ \tag{13}
\]
\[
HS^- + H_2O \rightleftharpoons S^{2-} + H_3O^+ \tag{14}
\]
3.4.3. Corrosion Mechanism in H$_2$S + O$_2$

The corrosion mechanism of copper in LPG with H$_2$S + O$_2$ is a chemical corrosion process. The corrosion process is carried out according to Equations (10), (11) and (17)–(19). Figure 13 displays a schematic diagram of the corrosion process in LPG containing H$_2$S + O$_2$. In the first step, H$_2$S and O$_2$ molecules in LPG adsorb on the copper surface. Then, the chemical reaction of copper with H$_2$S and O$_2$ molecules generate Cu$_2$S, H$_2$ and Cu$_2$O, respectively. Part of Cu$_2$O is further oxidized to CuO by O$_2$. The corrosion mechanism shows that the presence of only O$_2$ will not significantly promote the corrosion grade of the copper sheet, which is consistent with the experimental results. In this condition, the peak of CuO does not appear in the XRD results. However, a small amount of CuO was detected in XPS, indicating that the content of CuO is quite low in corrosion products. With the FTIR spectrum, the amount of Cu$_2$O is significantly more than CuO, which implies Cu$_2$O is more stable than CuO.

\[
2Cu + S^{2-} \rightleftharpoons Cu_2S + 2e^- \quad (15)
\]

\[
2H_2O^+ + 2e^- \rightleftharpoons 2H_2O + H_2 \quad (16)
\]

\[
O_2(g) \rightleftharpoons O_2(ads) \quad (17)
\]

\[
O_2(ads) + 4Cu \rightleftharpoons 2Cu_2O \quad (18)
\]

\[
O_2(ads) + 2Cu_2O \rightleftharpoons 4CuO \quad (19)
\]
Figure 13. Schematic diagram of corrosion steps of copper sheet in LPG with $\text{H}_2\text{S} + \text{O}_2$: (a) step 1, (b) step 2.

3.4.4. Corrosion Mechanism in $\text{H}_2\text{S} + \text{H}_2\text{O} + \text{O}_2$

The corrosion mechanism of copper in LPG containing $\text{H}_2\text{S} + \text{H}_2\text{O} + \text{O}_2$ is an electrochemical corrosion process. The corrosion process is carried out according to the Equations (12)–(16) and (20)–(22). The electrochemical corrosion process can be illustrated by the schematic diagram in Figure 14. Firstly, $\text{H}_2\text{O}$ in LPG exists in the form of a water film on the copper surface. Two electrochemical reactions happen at the interface. The dissolution of $\text{H}_2\text{S}$ in the water film leads to the electrochemical reaction in Equations (12)–(16). Meanwhile, the dissolution and diffusion of $\text{O}_2$ also cause another electrochemical corrosion reaction, as in Equations (20)–(22), which is the oxygen depolarization process. After $\text{H}_2\text{S}$ and $\text{O}_2$ molecules in LPG dissolve into the water film to form $\text{H}_2\text{S}(l)$ and $\text{O}_2(\text{ads})$, $\text{H}_2\text{S}(l)$ is further hydrolysed into a large amount of $\text{HS}^-$, $\text{H}_3\text{O}^+$ and a small amount of $\text{S}^{2-}$. Cu loses electrons to form $\text{Cu}_2\text{S}$ and $\text{Cu}_2\text{O}$ with $\text{S}^{2-}$ and $\text{OH}^-$, according to the anodic reaction of Equations (15) and (22) [46]. $\text{H}_2\text{O}^+$ and $\text{O}_2(\text{ads})$ obtain electrons from copper to form $\text{H}_2$, $\text{H}_2\text{O}$ and $\text{OH}^-$, which are regarded as cathode reactions (Equations (16) and (21)) [34,35,47]. Because the $\text{H}_3\text{O}^+$ in the water is consumed in large quantities, it is conducive to the ionization of water to move to the right to generate a large amount of $\text{OH}^-$, which increases the pH of the water film. A large amount of $\text{OH}^-$ is not only conducive to the dissolution of $\text{H}_2\text{S}$ in LPG in the water film, improving the solubility of $\text{H}_2\text{S}$, but is also conducive to the continuous hydrolysis of $\text{H}_2\text{S}(l)$ and $\text{HS}^-$ in the water film to form a large amount of $\text{HS}^-$ and $\text{S}^{2-}$, which promotes the formation of lots of $\text{Cu}_2\text{S}$ precipitates. Thereby, the solubility of $\text{H}_2\text{S}$ in the water film is further increased to promote the corrosion of copper by $\text{H}_2\text{S}$. Figure 14a–c are schematic diagrams of corrosion steps in LPG containing $\text{H}_2\text{S} + \text{H}_2\text{O} + \text{O}_2$. Combined with the previous theoretical analysis and Figure 14, it is shown that when both $\text{O}_2$ and $\text{H}_2\text{O}$ exist in LPG, the corrosion grade of copper will be significantly increased. A large amount of $\text{Cu}_2\text{S}$ and $\text{Cu}_2\text{O}$ will be generated, which is consistent with the previous experimental results of the synergistic effect of humidity and $\text{O}_2$. Moreover, $\text{Cu}_2\text{O}$ is thermodynamically more stable than $\text{Cu}_2\text{S}$ (the standard free energies of formation at room temperature for $\text{Cu}_2\text{O}$ and $\text{Cu}_2\text{S}$ are $-34.98$ and $-20.6$ kcal/mole, respectively [27]), indicating that $\text{Cu}_2\text{O}$ is preferentially formed at the same conditions. Therefore, the amounts of corrosion products in $\text{Cu}_2\text{O}$ are more than $\text{Cu}_2\text{S}$. This conclusion is consistent with the results of XRD and EDS. In addition, a large amount of $\text{Cu}_2\text{O}$ in XPS and FTIR also proves it.

\begin{align}
\text{O}_2(\text{g}) & \rightleftharpoons \text{O}_2(\text{l}) \quad (20) \\
\text{O}_2 (\text{l}) + 2\text{H}_2\text{O} + 4\text{e}^- & \rightleftharpoons 4\text{OH}^- \quad (21) \\
2\text{Cu} + 2\text{OH}^- & \rightleftharpoons \text{Cu}_2\text{O} + \text{H}_2\text{O} + 2\text{e}^- \quad (22)
\end{align}
Conclusions

In this paper, the influence of humidity and O$_2$ on copper corrosion in H$_2$S-containing LPG was studied. The corrosion products were characterized and analysed to reveal the corrosion mechanism. The following conclusions were obtained:

1. In H$_2$S-containing LPG, RH has pronounced influence on the corrosion grade of copper. The variation in the CP with RH in LPG is a linear relationship.
2. The presence of O$_2$ in dry H$_2$S has limited influence on the corrosion of copper. The CP decreases linearly with the increase in O$_2$ concentration. In the presence of different RHs, the CP always follows a negative exponential function with O$_2$ concentration.
3. Surface morphologies of corrosion products obtained in different environments are quite different. Gas humidity and the presence of O$_2$ notably affect the microscopic morphology of corrosion products. In individual H$_2$S, the morphology of copper corrosion products is a regular hexagon block with sharp edges and corners. In H$_2$S + H$_2$O (100% RH), the morphology of copper corrosion products is uniform spherical shape. In H$_2$S + O$_2$, the morphology of copper corrosion products is irregular in shape and size. In H$_2$S + H$_2$O + O$_2$, the morphology of the corrosion products is a regular hexagon block with sharp edges and corners, spherical and irregular in shape and size.
4. In H$_2$S-containing LPG, RH and O$_2$ have obvious influence on the composition and distribution of corrosion products. In individual H$_2$S, the corrosion product of copper is only Cu$_2$S. In H$_2$S + H$_2$O, corrosion products of copper are mainly Cu$_2$S. In H$_2$S + O$_2$, corrosion products of copper are composed of a large amount of Cu$_2$S and a small amount of CuO and Cu$_2$O. In H$_2$S + H$_2$O + O$_2$, corrosion products are composed of a large amount of Cu$_2$O, Cu$_2$S and a small amount of CuO.
5. The corrosion mechanism of copper in LPG in the presence of different corrosive gases was proposed. The corrosive gas influences the corrosion mechanism remarkably. In individual H$_2$S and H$_2$S + O$_2$, the corrosion process is chemical in nature. H$_2$S and O$_2$
react with copper directly at the interface. The corrosion mechanism of copper in LPG containing \( \text{H}_2\text{S} + \text{H}_2\text{O} \) and \( \text{H}_2\text{S} + \text{H}_2\text{O} + \text{O}_2 \) is an electrochemical corrosion process. In \( \text{H}_2\text{S} + \text{H}_2\text{O} \), the corrosion proceeds with an anodic reaction of copper oxidization and a cathodic reaction of traditional hydrogen depolarization. In \( \text{H}_2\text{S} + \text{H}_2\text{O} + \text{O}_2 \), two different electrochemical reactions happen: one is the same as in \( \text{H}_2\text{S} + \text{H}_2\text{O} \), and the other electrochemical reaction displays as the corrosion of \( \text{O}_2 \) in neutral medium, in which the cathodic process is oxygen depolarization.
