**Publisher's Disclaimer.** E-publishing ahead of print is increasingly important for the rapid dissemination of science. The *Monaldi Archives for Chest Disease* is, therefore, E-publishing PDF files of an early version of manuscripts that undergone a regular peer review and have been accepted for publication, but have not been through the copyediting, typesetting, pagination and proofreading processes, which may lead to differences between this version and the final one. The final version of the manuscript will then appear on a regular issue of the journal. E-publishing of this PDF file has been approved by the authors.

Abstract
Lung cancer is the leading neoplastic form worldwide for both incidence and mortality and represents the largest contributor to new cancer diagnosis. Cardiac extensions of a pulmonary neoplasm are rare and dramatically under-diagnosed because of the extreme variability of clinical presentation and frequently are expression of an advanced-stage primary lung cancer. The invasion often happens through pulmonary veins in absence of a clear respiratory impairment. Symptoms related to the cardiac involvement as the first presentation of a malignant pulmonary neoplasm are very uncommon and related with poor outcome. Here we present a case of invasion of the left atrium of a pulmonary neoplasm with initial cardiac manifestations and a laboratory finding of hypercalcemia.

Key words: pulmonary neoplasm; cardiac extension of lung malignancy; hypercalcemia; echocardiography.

Introduction
Left atrial invasion of a pulmonary cancer, happening via pulmonary veins, is a non-common extension of the respiratory neoplasm [1]. This invasion can be considered a life-threatening event, expression of an advanced-stage disease and can potentially be responsible for several
Complications such as obstructed pulmonary veins’ flows, atrio-ventricular block, atrial fibrillation, ventricular arrhythmias, and others [2]. Lung malignancies are also often responsible for hypercalcemia as an expression of paraneoplastic syndromes and because of bone metastases [3].

Case Report

A 48 years-old man was taken to our Emergency Department because of sudden onset of palpitations and dyspnea at rest. He also reported progressively worsening cough and hyposthenia at lower limbs. No history of cardiovascular risk factors was referred except for a smoke-custom of nearly 20 cigarettes/day. He also referred a weight loss of about 10 kgs in the last year. Tachycardia and systolic murmur were evidenced at cardiac examination. Pulmonary auscultation revealed a slightly diminished vesicular murmur at left hemithorax. The 12-leads EKG shown a paroxysmal supraventricular tachycardia (150 beats/min). Blood pressure was 115/70 mmHg, and SpO\textsubscript{2} was 92%. The carotid sinus massage, performed in attempt to correct the supraventricular tachycardia, resulted ineffective but e.v. injection of 10 mg of Verapamil diluted in 250 cc of physiological solution was able to rapidly restore sinus rhythm. Afterwards, the repeated 12 leads EKG showed a sinus rhythm at 90 beats/min, RBB and J-wave in the right precordial derivations (fig. 1). The EKG finding of an “Osborn wave”, except for hypothermia, is likely due to an increase of Ca++ serum levels [4]. Additional EKG abnormalities in hypercalcemia also include shortened Q-T interval and biphasic T wave in the right derivations. In this case, the Ca++ concentration was of 2.13 mmol/L. 2D-Echocardiography showed values of systolic and diastolic LV dimensions in the normal range. Right ventricle was not dilated, and a valvular tricuspid insufficiency was found. In addition, lateral wall of LV was hypokinetic and LVEF%, evaluated with the Simpson method, was of 50%. Finally, left atrium revealed a large mass occupying almost completely this chamber. The mass pressed atrial septum, in the absence of an evident inter-atrial shunt (fig. 2A). Three-dimensional echocardiography confirmed the left atrial invasion of the mass (fig.2B) and a trans-mitral pattern of diastolic disfuction was recorded (fig. 3). Chest radiography showed a mass largely occupying the inferior lobe of left lung, indissociable from the pulmonary tissue. CT scan confirmed the pulmonary image and evidenced its extension in the left atrium through the pulmonary vein occupying it nearly completely (fig. 4). Head CT scan did not show any metastases. On the contrary, multiple metastases were found at whole-body bone scintigraphy.

The morphological and microscopic findings demonstrated that the neoplasm was an adenocarcinoma and it was managed with a combination of surgery and adjuvant therapy.
performed for pulmonary neoplasm, the intracardiac tumoral mass and pulmonary vein tumor. On histopathologic examination, the tumoral mass resulted composed of large pleomorphic cells with ovoid nucleoli. But, three months after surgery, brain TC-scan evidenced multiple brain metastases. The clinical conditions progressively worsened, and the patient died 8 months after surgical treatment.

Discussion

Left atrial extension of a lung tumor via pulmonary veins is a non-frequent event mimicking left atrial myxoma, firstly showing with cardiac symptoms [5,6]. Echocardiography is a method to non-invasively detect the extension of lung neoplasm in the left atrium. Apart from the numerous cardiac complications, the patients with extension of lung cancer into left atrium may have some other organs impairments, such as ischemic stroke [7,8]. In the reported case, the laboratory finding of hypercalcemia was a cause of suspect the cancer [9]. Several mechanisms can be responsible for hypercalcemia in malignancy, including parathyroid hormone-related peptide and osteolytic metastases-related hypercalcemia [10]. It’s well known, in fact, that Parathyroid Hormone-related Protein (PTHrP) can be responsible for humoral hypercalcemia of malignancies (HHM) through endocrine action and tumor-induced bone destruction [11]. It must be also added that, in our patient, the multi-parametric evaluation of patient (clinical symptoms, physical examination, EKG, echocardiography, chest x-ray, CT scan and laboratory findings) were useful to suspect and recognize the pulmonary malignancy and its left atrial extension [12,13].
