(Received 24 March 2010; accepted 11 September 2010; published online 5 October 2010)

We show that the holonomy of a connection defined on a principal composite bundle is related by a non-Abelian Stokes theorem to the composition of the holonomies associated with the connections of the component bundles of the composite. We apply this formalism to describe the non-Abelian geometric phase (when the geometric phase generator does not commute with the dynamical phase generator). We find then an assumption to obtain a new kind of separation between the dynamical and the geometric phases. We also apply this formalism to the gauge theory of gravity in the presence of a Dirac spinor field in order to decompose the holonomy of the Lorentz connection into holonomies of the linear connection and of the Cartan connection. © 2010 American Institute of Physics.

I. INTRODUCTION

A composite bundle is a tower of bundles $E(T,F_{2})\to T(B,F_{1})\to B$ [the notation $T(B,F)\to B$ denotes a locally trivial fiber bundle, with base space $B$, typical fiber $F$, total space $T$, and projection $\pi$, with $B$, $F$, and $T$ being three $C^\infty$-manifolds and $\pi$ being a surjective map]. The concept of composite bundle was introduced by Sardanashvily in Ref. 1, with $E(T,F_{2})\to T$ a vector bundle, to describe both the non-Abelian geometric phase and the non-Abelian dynamical phase. Sardanashvily2,3 and Tresguerres4 have also used composite bundles to describe the gauge theory of gravity. To complete the description of a non-Abelian geometric phase with a non-Abelian dynamical phase, we have introduced in Ref. 5 the concept of principal composite bundle. A principal composite $P(M,G)$-bundle $P_{s}(S,G)\to S(R,M)\to M$ mimes a principal bundle, where a base fiber bundle $S(R,M)\to R$ plays the role of the base manifold, and where a structure principal $G$-bundle $P(M,G)\to M$ plays the role of the structure group ($R$, $M$, $S$, $P$, and $P_{s}$ are $C^\infty$-manifolds and $G$ is a Lie group). We have shown that a principal composite bundle defines a locally defined $G$-bundle $P_{s}(M\times R,G)\to M\times R$ called total bundle, and two kinds of “leaf” of fibers. One consists of bundles isomorphic to $P(M,G)\to M$, and the others are called transversal $G$-bundles $(Q_{s}(N,G)\to N)$. In the present paper, we specify the principal composite bundle structure, particularly from the viewpoint of the local data and of the torsion of the total bundle. Moreover, we study the holonomy of a composite connection and we show that it is related by a non-Abelian Stokes theorem to the product of the holonomy of the structure bundle connection by the holonomy of one of the transversal bundle connections.

This paper is organized as follows. Section II presents the principal composite bundle geometry. Section III studies composite connections and the associated holonomies. The link between composite holonomies and geometric phases, when the geometric phase generator does not commute with the dynamical phase generator, is studied in Sec. IV. Under a relevant assumption we
find that the non-Abelian phase is the product of the non-Abelian geometric phase and of the non-Abelian dynamical phase with fixed adiabatic parameters. Finally, we consider the composite holonomies arising with a Dirac spinor field transport in a curved space-time.

A note about the notations used here: the symbol "=" denotes the equality between two manifolds, the symbol "→" denotes an inclusion between two sets. \( \Omega^0(M, g) \) denotes the set of the \( g \)-valued \( n \)-forms of the manifold \( M \). \( \text{d} M \) denotes the exterior differential of \( M \). \( T M \) denotes the space of tangent vectors of \( M \) at \( x \in M \) and \( T^\ast M \) denotes the space of tangent vector fields of \( M \) (the tangent bundle of \( M \)). \( L \) \( M \) denotes the space of smooth closed loops in \( M \) with base point \( x \). \( f \circ g(x) \) denotes the composition \( f(g(x)) \). \( \Gamma(U, P) \) denotes the set of local sections of a fiber bundle \( P \rightarrow M \) over \( U \subseteq M \).

II. THE PRINCIPAL COMPOSITE BUNDLE GEOMETRY

This section presents the relevant definitions concerning the principal composite bundles. The first part presents the global theory (as in Ref. 5) but with enlightenment concerning the torsion of the total bundle; the second part introduces the local theory (which is not treated in Ref. 5).

A. Global geometry of a principal composite bundle

**Definition 1:** (Principal composite bundle) Let \( G \) be a Lie group and \( P(M, G) \) \( \rightarrow M \) be a principal \( G \)-bundle over a manifold \( M \). A principal composite \( P(M, G) \)-bundle is a tower of fiber bundles \( P \ast(S, G) \rightarrow S(R, M) \rightarrow R \), such that

- \( \forall y \in R, \pi^{-1}_S(y) = M \),
- for every good open cover \( \{V^i\} \) of \( R \), there exists a diffeomorphism \( \chi^i_S: \pi^{-1}_S(V^i) \rightarrow V^i \times M \),
- \( \forall y \in V^i, \pi^{-1}_S(\pi^{-1}_S(y)) = \chi^i_S \).

\( P(M, G) \rightarrow M \) is called the structure bundle of the principal composite bundle.

(A good open cover of \( R \) is a set of simply connected contractible open sets covering \( R \).) \( \chi^i_S \) is the map induced in the bundles by \( \chi^i_S = \chi^i_S \pi^{-1}_S(y) \) [the fiber diffeomorphism of \( S(R, M) \) over \( y \)], i.e., it is the bundle isomorphism such that the following diagram commutes:

\[
\begin{array}{ccc}
P & \xrightarrow{\pi^{-1}_S(\pi^{-1}_S(y))} & P \\
\downarrow \pi_p & & \downarrow \pi_p \\
S & \xrightarrow{\chi^i_S} & M \\
\downarrow \pi_S & & \\
R & \xrightarrow{\{y\}} & \\
\end{array}
\]

As a principal bundle defines a total space which is locally a Cartesian product of manifolds, a principal composite bundle defines a total space which is locally a fiber bundle.

**Definition 2:** (Total twisted bundle of a principal composite bundle) Let \( P_\ast(S, G) \rightarrow S(R, M) \) \( \rightarrow R \) be a principal composite \( P(M, G) \)-bundle. Let \( \phi^a_\ast: U^a \times G \rightarrow \pi^{-1}_P(U^a) \subseteq P \) be the local trivialization of \( P(M, G) \) (\( \{U^a\}_a \) being a good open cover of \( M \)). We call total twisted bundle of \( P_\ast \rightarrow S \rightarrow R \), the set of principal \( G \)-bundles \( \{P_\ast(M \times V^i, G) \rightarrow M \times V^i\}_i \), defined by the following local trivialization:
FIG. 1. Scheme of a principal composite $P(M,G)$-bundle $P_+(S,G) \to S(R,M) \to R$. A single fiber over $(x,y)$ is represented by a dotted line. This fiber belongs to the longitudinal leaf of fibers $\chi_\mathbf{x}^\pm P$ and to the transversal leaf of fibers $Q_x$.

$$
\phi^a_{++} : U^a \times V^i \times G \to P_+^i \quad (x,y,g) \mapsto \chi_\mathbf{x}^{ij} \phi^a_p(x,g),
$$
where $P_+^i = \pi_+^{-1}(\pi_+^{-1}(V^i))$ with the projection defined by $\forall p \in P_+^i$, $\pi_+^i(p) = (\chi_\mathbf{x}^{ij} \pi_+^i (p) ; \pi_+^i)$. 

Since $\chi_\mathbf{x}^{ij} \phi^a_p(s,G) = \pi_+^{-1}(\chi_\mathbf{x}^{ij}(x))$, for each $y \in V^i \cap V^j$, $\chi_\mathbf{x}^{ij} \phi^a_p(\chi_\mathbf{x}^{ij} \pi_+^i (x),G) = \chi_\mathbf{x}^{ij} \phi^a_p(x,G)$.

**Definition 3:** (Torsion functions of the twisted total bundle) We call torsion functions of the total twisted bundle of a principal composite $P(M,G)$-bundle $P_+(S,G) \to S(R,M) \to R$, the automorphisms of $M$ defined for all $y \in V^i \cap V^j$ by

$$
\varphi_y^{ij} : M \to M \\
x \mapsto \chi_{\mathbf{x}^\mp}^{-1}(x),
$$
where $\varphi_y^{ij}$ represents the torsion of $\{P_+(M \times V^i,G)\}$, since

$$
\phi^a_{++}(x,y,G) = \phi^a_{++}(\varphi_y^{ij}(x),y,G).
$$
The total twisted bundle is a principal $G$-bundle if and only if $\varphi_y^{ij} = id_M$, i.e., if $S=R \times M$ [the bundle $S(R,M)$ is trivial].

There are three notions of fiber in a principal composite bundle (see Fig. 1). One is the usual fiber of the total bundle of the composite, i.e., $\pi_+^{-1}(x,y)$ for $(x,y) \in M \times V^i$. The second kind plays the role in the principal composite bundle of the fiber diffeomorphic to the structure group in a principal bundle, i.e., $\pi_+^{-1}(\pi_+^{-1}(y)) = \chi_\mathbf{x}^\pm P$. We call it a longitudinal leaf of fibers. The third kind has no analog in a simple principal bundle; it is a transversal leaf of fibers.

**Definition 4:** (Transversal bundles) Let $P_+(S,G) \to S(R,M) \to R$ be a principal composite $P(M,G)$-bundle and $\phi^a_{++}$ be the local trivialization of its total twisted bundle. We call transversal bundle over $x \in U^a \subset M$ the set of principal $G$-bundles $\{Q_x^{ai}(V^i,G) \to V^i\}$, defined by the following local trivializations:

$$
\phi_y^{ai} : V^i \times G \to Q_x^{ai} \subset P_+^i \\
(y,g) \mapsto \phi^a_{++}(x,y,g).
$$
The projection of a transversal bundle is then defined by $\forall q \in Q_x^{ai}$, $\pi_{Q_x}^a(q) = \pi_+ \pi_+^a(q)$.
We remark that if $x \in U^\alpha \cap U^\beta$ then there exists two diffeomorphic transversal bundles over $x$: $Q_x^\alpha \simeq Q_x^\beta$. We denote by $\phi^{\alpha \beta(i)}_{Q_x}: Q_x^\beta \to Q_x^\alpha$ this diffeomorphism. $\forall x \in U^\alpha \cap U^\beta \cap U^\gamma$ and for $q \in Q_x^\beta$, $\phi^{\alpha \beta(i)}_{Q_x}(q) = \phi^{\alpha \beta(i)}_{Q_x} \cdot (q \cdot h_x^{\alpha \beta(i)}(\pi^\alpha_{Q_x}(q)))$ with $h_x^{\alpha \beta(i)}(y) \in G$ (the dot in the preceding expression denotes the right action of $G$ on $Q_x^\beta$).

Property 1: The family of the transversal bundles $\{Q_x^\alpha(R,G) \to R\}_{x \in U^\alpha \cap U^\beta}$ of a principal composite bundle is torsion free, i.e., $h_x^{\alpha \beta(i)}(y) = e$ ($e$ is the identity element of $G$).

This property follows from the two following calculations:

\[ \forall y \in V^i, \]
\[ \Lambda_{x^i}^{-1}(y) = \Lambda_{x^i}^{-1}(y), \]
\[ \Lambda_{x^i}^{-1}(x) = \phi_{x^i \cdot \phi_{x^i}}^{-1} \pi^i_{x^i}(x). \]

Remark: Let $\{W^\alpha\}_{\alpha,i}$ be the good open cover of $S$ defined by $W^\alpha = \bigcup_{y \in V^i} \Lambda_{x^i}^{-1}(U^\alpha)$. The local trivialization of the principal $G$-bundle $P_x(S,G) \to S$ is

\[ \phi^\alpha_{x^i}: (s,g) \mapsto \Lambda_{x^i}^{-1}(s \cdot \phi^\alpha_{x^i}(s) \cdot g), \]

**B. Local data defining a principal composite bundle**

A principal bundle, as $P(M,G) \to M$, is totally determined by the knowledge of the manifolds $P$ and $M$ and of the local diffeomorphism $\phi^\alpha_{x^i}: U^\alpha \times G \to P$ [or equivalently the fiber diffeomorphism $\phi^\alpha_{x^i} = \phi^\alpha_{x^i}(x,\cdot)$]. Indeed, it is often more practical to determine the structure of a principal bundle by using entities defined only with $M$ and $G$ (without any explicit reference to $P$). Indeed the explicit geometry of the manifold $P$ is often known. The local data defining a principal bundle are the transition functions $g^\alpha_{x^i} \in \Omega^0(U^\alpha \cap U^\beta, G)$ (see Ref. 6) which are related to the local diffeomorphisms $\phi^\alpha_{x^i}$ by

\[ \forall x \in U^\alpha \cap U^\beta, \phi^\beta_{x^i}(x) = \phi^\alpha_{x^i}(x, g^\alpha_{x^i}(x)). \] (1)

They satisfy the cocycle relations

\[ \forall x \in U^\alpha \cap U^\beta \cap U^\gamma, g^\alpha_{x^i}(x)g^\beta_{x^i}(x) = g^\gamma_{x^i}(x), \] (2)

\[ \forall x \in U^\alpha \cap U^\beta, g^\alpha_{x^i}(x) = g^\beta_{x^i}(x)^{-1}. \] (3)

Since $\Lambda_{x^i}^{-1}(x \cdot \phi^\beta_{x^i}(x,G)) = \Lambda_{x^i}^{-1}(x \cdot \phi^\beta_{x^i}(x,G))$, there exists $g^\beta_{x^i} \in \Omega^0(V^i \cap V^j, G)$, such that

\[ \Lambda_{x^i}^{-1}(x \cdot \phi^\beta_{x^i}(x,G)) = \Lambda_{x^i}^{-1}(x \cdot \phi^\beta_{x^i}(x,G)). \]

Property 2: $\forall x \in U^\alpha \cap U^\beta$ and $\forall y \in V^i \cap V^j$, we have

\[ g^\alpha_{x^i}(x)g^\beta_{x^i}(y) = g^\gamma_{x^i}(y)g^\beta_{x^i}(y). \] (4)

This property follows from the two following calculations:

\[ g^\alpha_{x^i}(x)g^\beta_{x^i}(y) = g^\gamma_{x^i}(y)g^\beta_{x^i}(y). \]
The transition functions of the total twisted bundle of a principal composite $P(M,G)$-bundle $P_+(S,G) \to S(R,M) \to R$ are defined by

$$\forall (x,y) \in U^a \cap U^\beta \times V^i \cap V^j, \quad g^{(a)(\beta)}_{++}(x,y) = g^{a\beta}_{P^*}(x,g^{(a)}_{Q^*}(y)) = g^{a\beta}_{P^*}(x,g^{(\beta)}_{Q^*}(y)).$$

They are related to the local diffeomorphisms by

$$\forall (x,y) \in U^a \cap U^\beta \times V^i \cap V^j, \quad \phi^{(\beta)}_{++}(\phi^{(a)}_{Y^i}(x),y,e) = \phi^{a\beta}_{++}(x,y,g^{(a)}_{Q^*}(x),y).$$

**Property 3:** The transversal transition functions satisfy the twisted cocycle relation

$$\forall y \in V^i \cap V^j \cap V^k, \quad g^{jk(a)}_{++}(y) = g^{jk(a)}_{Q^*}(y)g^{jk(a)}_{Q^*}(x).$$

This property follows from the two following calculations:

$$\chi^{a\beta}_{S^*}g^{a\beta}_{P^*}(x,g^{(a)}_{Q^*}(y)) = \chi^{a\beta}_{S^*}(x,g^{(a)}_{Q^*}(y)),$$

$$\chi^{a\beta}_{S^*}g^{a\beta}_{P^*}(x,g^{(a)}_{Q^*}(y)) = \chi^{a\beta}_{S^*}(x,g^{(a)}_{Q^*}(y)).$$

**Property 4:** The transition functions of the total twisted bundle satisfy the twisted cocycle relation

$$\forall (x,y) \in U^a \cap U^\beta \cap U^\gamma \times V^i \cap V^j \cap V^k, \quad g^{(a)(\gamma)}_{++}(x,y) = g^{(a)(\beta)}_{++}(x,y)g^{(\beta)(\gamma)}_{++}(\phi^{(a)}_{Y^i}(x),y).$$

Indeed we have

$$g^{(a)(\gamma)}_{++}(x,y) = g^{a\gamma}_{P^*}(x)g^{(\gamma)}_{Q^*}(y) = g^{a\gamma}_{P^*}(x)g^{(\gamma)}_{Q^*}(y)g^{jk(a)}_{Q^*}(y).$$

The twisted cocycle relation can be rewritten as

$$g^{(a)(\beta)}_{++}(x,y) = g^{(a)(\beta)}_{++}(x,y)g^{(\beta)(\gamma)}_{++}(x,y)g^{(\gamma)}_{++}(\phi^{(a)}_{Y^i}(x),y).$$
\[ h^{(a)(b)(\gamma)}(x,y) = g^{(a)(b)}(x,y)^{-1} g^{(b)(\gamma)}(x,y) \cdot \varphi_{ij}(x,y). \]  

\[ h^{(a)(b)(\gamma)} \in \Omega^0(U^\alpha \cap U^\beta \cap U^\gamma \times V^x \cap V^y \cap V^\delta, G) \] represents the obstruction to lift the total twisted bundle into a principal bundle. The notion of total twisted bundle introduced in this paper extends the notions of twisted bundle and bundle gerbes.7–10

**Proposition 1:** Let \( g^{(a)(b)}_+ \in \Omega^0(W^a \cap W^b, G) \) be the transition functions of the principal \( G \)-bundle \( P_+(S, G) \). These transition functions are related to the transition function of the total twisted bundle by

\[ g^{(a)(b)}_+(x,y) = g^{(a)(b)}_+(x, \chi^{-1}_y(x)). \]

Indeed \( \forall s \in W^a \cap W^b \) we have

\[ \phi^{(b)}_+(s,e) = \phi^{(a)(b)}_+(s, g^{(a)(b)}_+(s)) \]

and

\[ \phi^{(b)}_+(\varphi^i_j(x), y, e) = \phi^{(a)(b)}_+(x, \chi^{-1}_y(x), e). \]

\[ \phi^{(a)(b)}_+(x, y, g) = \phi^{(a)(b)}_+(x, \chi^{-1}_y(x), g). \]

We can note that the usual cocycle relation concerning \( g^{(a)(b)}_+ \) involves the twisted cocycle relation concerning \( g^{(a)(b)}_+ \),

\[ g^{(a)(b)}_+(x, \chi^{-1}_y(x), g^{(a)(b)}_+(x, y)) = g^{(a)(b)}_+(x, \chi^{-1}_y(x)). \]

**Proposition 2:** A composite principal \( P(M, G) \)-bundle over \( S(M, R) \to R \) is completely determined by the knowledge of automorphisms \( \varphi^i_j : M \to M \) and functions \( g^{(a)(b)}_+ \in \Omega^0(U^a \cap U^b \times V^x \cap V^y, G) \) such that \( g^{(a)(b)}_+(x,y) \) is independent of \( y \in R \) and of \( i \), and satisfying the twisted cocycle relations

\[ \forall (x,y) \in U^a \cap U^b \cap U^\gamma \times V^x \cap V^y, \quad g^{(a)(b)}_+(x,y) g^{(a)(b)}_+(y,x) = g^{(a)(b)}_+(x,y). \]

Indeed, we can reconstruct the manifold \( S \) by

\[ S = \bigcup_i V^i \times M/\sim \quad (y, x) \sim (y', x') \Leftrightarrow y = y' \quad \text{and} \quad y \in V^x \cap V^y \Rightarrow x' = \varphi^i_j(x) \]

and the manifold \( P_+ \) by

\[ P_+ = \bigcup_{a,i} W^a \cap G/\sim \quad (s, g) \sim (s', g') \Leftrightarrow s = s' \quad \text{and} \quad s \in W^a \cap W^b \Rightarrow g' = g^{(a)(b)}_+(s). \]

**III. COMPOSITE CONNECTIONS AND COMPOSITE HOLONOMIES**

**A. Global definition of a composite connection**

The fibers of \( P_+ \) being diffeomorphic to \( G \), there exists a tangent vector subspace, such that \( T_rP_+ \supseteq V_rP_+ \cong g \) for \( r \in P_+ \) (where \( g \) is Lie algebra of \( G \)) called the space of vertical tangent vectors (see Ref. 6). A connection is a choice of a supplementary subspace \( H_rP_+ \) called the space of horizontal tangent vectors, \( T_rP_+ = V_rP_+ \oplus H_rP_+ \). We want to reduce the choice of the horizontal tangent space to be compatible with the composite structure.
Definition 5: (Composite connection) Let \( P_+(S, G) \rightarrow S(R, M) \rightarrow M \) be a principal composite \( P(M, G) \)-bundle. A composite connection is a choice of a horizontal tangent space \( H_+P \) at each point \( r \) of \( P_+ \), such that there exists a horizontal tangent space \( H_+P \) at each point \( p \) of \( P \) with \( \chi^{ij}_{S+}p \subset H_{\chi^{ij}_{S+}}(y)P \).

\( \chi^{ij}_{S+} \) denotes the tangent map of \( \chi^{ij}_{S+} \) (the lower star denotes the push-forward).

A connection being defined by a 1-form (for which the horizontal tangent space is its kernel, see Ref. 6), we have the following definition.

Definition 6: (Composite connection 1-form) Let \( P_+(S, G) \rightarrow S(R, M) \rightarrow M \) be a principal composite \( P(M, G) \)-bundle. A connection 1-form \( \omega \in \Omega^1(P_+), g \) is a composite principal connection 1-form if there exists a connection 1-form \( \omega_+ \in \Omega^1(P_+), g \), such that \( \forall y \in V^i, \chi^{ij}_{S+}P \omega = \omega_+, \) where

\[ i: \pi^+_+^{-1}(\pi^+_S(y)) \rightarrow P_+ \text{ is the canonical injection.} \]

\( \chi^{ij}_{S+} \) denotes the cotangent map of \( \chi^{ij}_{S} \) (the second upper star denotes the pull-back). The important property of a composite connection 1-form is that \( \chi^{ij}_{S+} P \omega \) is independent of \( y \) and of \( i \).

Let \( i^+_*: Q^\ast_+ \rightarrow P_+ \) be the canonical injection. The transversal bundle is endowed with the connection 1-form \( \omega_+ = i^+_* \omega \in \Omega^1(Q^\ast_+, g) \).

B. Local data associated with a composite connection

Let \( \omega \in \Omega^1(P_+, g) \) be a composite connection of \( P_+(S, G) \rightarrow S(R, M) \rightarrow R \). Let \( \sigma^{ij}_{M \times R} \in \Gamma(U^a \times V^i, P_+) \) be a local section of the principal bundle \( P_+(M \times V^i, G) \), such that

\[ \forall (x, y) \in U^a \cap U^b \times V^i \cap V^j, \quad \sigma^{ij}_{M \times R}(\phi^{ij}_+(x, y)) \equiv \sigma^{ij}_{M \times R}(x, y) - g^{(a)(b)}_{M \times R}(x, y) \equiv \sigma^{ij}_{M \times R}(x, y). \] (31)

The gauge potential associated with the connection is \( A^{ij}_+=\sigma^{ij}_{M \times R} \omega \in \Omega^1(U^a \times V^i, g) \). By construction we have

\[ \forall (x, y) \in U^a \cap U^b \times V^i \cap V^j, \]

\[ \phi^{ij}_+A^{ij}_+(x, y) = \frac{\partial \phi^{ij}_+(x, y)}{\partial \lambda^\mu} + \frac{\partial \phi^{ij}_+(x, y)}{\partial y^a} + A^{ij}_+(x, y) \cdot d\mu^a, \] (33)

where \( \phi^{ij}_+(x) \) is the \( v \)-th coordinates of the point \( \phi^{ij}_+(x) \in M \).

Let \( F^{ij}_+=dA^{ij}_+ + A^{ij}_+ \wedge A^{ij}_+ \in \Omega^2(U^a \times V^i, g) \) be the curvature of the principal composite bundle. By construction we have

\[ \phi^{ij}_+F^{ij}_+(x, y) = g^{(a)(b)}_{M \times R}(x, y) \equiv g^{(a)(b)}_{M \times R}(x, y). \] (34)

We can use the language of the 2-connections on the total twisted bundle (see Ref. 7–10),

\[ A^{ij}_+(x, y) = \frac{\partial \phi^{ij}_+(x, y)}{\partial \lambda^\mu} + \frac{\partial \phi^{ij}_+(x, y)}{\partial y^a} + A^{ij}_+(x, y) \cdot d\mu^a, \] (33)

where \( A^{ij}_+(x, y) = A^{ij}_+(x, y) - \phi^{ij}_+A^{ij}_+(x, y) \) is the potential of the 2-connection. By construction we have

\[ F^{ij}_+(x, y) = g^{ij}(\pi^+_S(y))^{-1}F^{ij}_+(x, y) \equiv F^{ij}_+(x, y) - \phi^{ij}_+F^{ij}_+(x, y), \] (36)
\[ = d_{M \times R} A_i^\alpha(x) + [A_i^\alpha(x,y), A^\alpha_i(x,y)] - A^\alpha_i(x,y) \wedge A^\alpha_i(x,y), \]  
\[ (37) \]

where \( F^\alpha_i \) plays then the role of the curving associated with the 2-connection (usually denoted by \( B \)).

C. The intertwining curvature

The transversal bundle \( Q^\alpha_i \) is endowed with the gauge potential

\[ A^\alpha_i = g^\alpha_i(x) A_i^\alpha(x,y), \]

where \( g^\alpha_i(x) \) is a \( \sigma_{M \times R}^\alpha(x,y) \)-dependent gauge potential of \( Q^\alpha_i \), the gauge potentials of \( Q^\alpha_i(R,G) \) and \( Q^\beta_i(R,G) \) are related by

\[ A^\alpha_i(y) = g^\alpha_i(x) A^\alpha_i(x,y) g^\beta_i(x). \]

\[ (39) \]

\[ \chi^{-1} \sigma_{M \times R}^\alpha(x,y) \in \Gamma(U^\alpha, P) \] is a \( (y,i) \)-dependent local section of the principal bundle \( P(M,G) \). With it we can define a \( (y,i) \)-dependent gauge potential of \( P \),

\[ A^\alpha_i = g^\alpha_i(x) A_i^\alpha(x,y), \]

\[ \forall x \in U^\alpha \cap U^\beta, \exists g^\alpha_i(x) \in G, \quad \chi^{-1} \sigma_{M \times R}^\alpha(x,y) \in \sigma_{M \times R}^\alpha(x,y) . \]

We note that

\[ A^\alpha_i(y) = g^\alpha_i(x) A^\alpha_i(x,y) g^\beta_i(x). \]

\[ (40) \]

Finally, we compute the curvature of the composite bundle, where \( \tilde{\alpha} \) is a \( \tilde{\sigma}_{M \times R}^\alpha(x,y) \)-dependent gauge transformation, indeed

\[ \forall (x,y) \in U^\alpha \times V^i, \quad \exists g^\alpha_i(x) \in G, \quad \chi^{-1} \sigma_{M \times R}^\alpha(x,y) \sigma_{M \times R}^\alpha(x,y) = \sigma_{M \times R}^\alpha(x,y). \]

\[ (41) \]

\[ \forall x \in U^\alpha \cap U^\beta \times V^i, \quad g^\alpha_i(x) g^\beta_i(x) = g^\alpha_i(x) g^\beta_i(x). \]

\[ (42) \]

\[ \forall x \in U^\alpha \cap U^\beta, \quad A^\alpha_i(x,y) = A^\alpha_i(x,y) = g^\alpha_i(x) A^\alpha_i(x,y) + g^\alpha_i(x) d_{M \times R} g^\alpha_i(x). \]

\[ (43) \]

\[ \forall x \in U^\alpha \cap U^\beta, \quad A^\beta_i(x,y) = A^\beta_i(x,y) = g^\alpha_i(x) A^\alpha_i(x,y) + g^\alpha_i(x) d_{M \times R} g^\alpha_i(x). \]

\[ (44) \]

The gauge potentials of the total, structure, and transversal bundles are related by

\[ A^\alpha_i(x,y) = A^\alpha_i(x,y) + A^\alpha_i(x,y) \]

\[ (45) \]

\[ = g^\alpha_i(x) A^\alpha_i(x,y) g^\alpha_i(x) + A^\alpha_i(x,y) + g^\alpha_i(x) d_{M \times R} g^\alpha_i(x). \]

\[ (46) \]

We prefer another gauge choice: \( \tilde{A}^\alpha_i(x,y) = g^\alpha_i(x) A^\alpha_i(x,y) g^\alpha_i(x) + A^\alpha_i(x,y) + g^\alpha_i(x) d_{M \times R} g^\alpha_i(x) \), in which we have

\[ \tilde{A}^\alpha_i(x,y) = A^\alpha_i(x,y) + A^\alpha_i(x,y), \]

\[ (47) \]

with \( \tilde{A}^\alpha_i(x,y) = g^\alpha_i(x) A^\alpha_i(x,y) g^\alpha_i(x) + A^\alpha_i(x,y) + g^\alpha_i(x) d_{M \times R} g^\alpha_i(x) \). We call this choice the gauge of decomposition since it isolates the gauge potential of \( P(M,G) \).

Finally, we compute the curvature of the composite bundle,
\[ F^a_i = d_{M \times R} A^a_i + A^a_i \wedge A^a_+ \]  
\[ = F^a_P + F^a_{Q_x} + d_{P,M} A^a_{Q_x} + [A^a_+, \tilde{A}^a_{Q_x}] \]  

where \( D^P_P = d_M + [A^a_+, \cdot] \) is the covariant differential associated with the connection of \( P(M, G) \), \( F^a_P \) is the curvature of \( P(M, G) \), and \( F^a_{Q_x} \) is the curvature of \( Q^a_x(V, G) \). We note that

\[ \forall (x,y) \in U^a \cap U^\beta \times V^\beta \cap V^\gamma, \quad \varphi^{ij} F^j_P = \frac{1}{g^{(\alpha)(\beta)}} F^a_{Q_x} + \frac{\varphi^{ij} \varphi^{j\beta} P^\alpha_{Q_x}}{g^{(\alpha)(\beta)}} \]  

where \( g^{(\alpha)(\beta)}(x,y) = g_{\alpha \beta}(x,y) g^{(\beta)(\alpha)}(x,y) \). We call \( D^P_P \tilde{A}^a_{Q_x} \) the intertwining curvature of the composite bundle, since it measures the covariant variations of the connection of \( Q^a_x(V, G) \) with respect to the variations of \( x \) [the covariance being defined with respect to the connection of \( P(M, G) \)].

### D. Composite holonomy

Let \( C_{M \times R} \in \mathcal{C}_{(x_0 \times y_0)}(M \times V) \) be a closed path in \( M \times V \), \( C_M \in \mathcal{L}_{x_0} M \) be its “image” in \( M \), and \( C_R \in \mathcal{L}_{y_0} V \) be its “image” in \( R \). The holonomy of the path \( C_{M \times R} \) in the total bundle \( P^a_x(M \times V^a_x, G) \) measures the difference along the fiber \( \pi^{(a)}_{x_0}(x_0, y_0) \) between the two end points of the open horizontal lift of the closed path \( C_{M \times R} \). It is defined by (see Ref. 6)

\[ \text{Hol}_{A_t}(C_{M \times R}) = 1^p_{C_{M \times R}} e^{\delta A}, \]  

where \( 1^p_{C_{M \times R}} \) is the path-ordering operator along \( C_{M \times R} \), i.e., \( 1^p_{C} e^{iA} \) is the solution of the following equation:

\[ \frac{d 1^p_{C} e^{iA}}{ds} = 1^p_{C} e^{iA} A_{\mu}^{(a)}(s) \frac{dx^{(a)}(s)}{ds}, \]

where \( s \mapsto x(s) \) is a parametrization of \( C \).

In the composite bundle, we are interested in the comparison between the holonomy in the total bundle \( \text{Hol}_{A_t}(C_{M \times R}) \) and the holonomies in the structure bundle \( \text{Hol}_{A^P}(C_M) \) and in a relevant transversal bundle (for example, the transversal bundle at the base point \( x_0 \) \( \text{Hol}_{A_{Q_0}}(C_R) \)). Ideally, we would prefer the composite holonomy to be the composition of the component holonomies:

\[ \text{Hol}_{A_t}(C_{M \times R}) = \text{Hol}_{A^P}(C_M) \text{Hol}_{A_{Q_0}}(C_R) \]  

Obviously this is not the case. The following theorem expresses the difference between the composite holonomy and the composition of the component holonomies by using the intertwining curvature (which measures precisely the intertwining between the two connections).

**Theorem 1:** Let \( P(S, G) \rightarrow S(R, M) \rightarrow R \) be a principal composite \( P(M, G) \)-bundle endowed with a composite connection defined by the gauge potential \( \tilde{A}^a_{Q_x}(x, y) = A^P_+(x) + \tilde{A}^a_{Q_x}(y) \) (within the gauge of decomposition). Let \( C_R \in \mathcal{L}_{y_0} R \). Let \( h \in \Gamma(C_R, S) \) be a local section of \( S(R, M) \) over \( C_R \). We suppose that

- there exists a local chart \( V \subset R \), such that \( C_R \subset V \),
- there exists a local chart \( U^a \subset M \), such that \( \chi^a h(C_R) \subset U^a \).

The difference between the composite holonomy of the section \( h \) in the principal composite bundle (which is defined as being the holonomy of \( C_{M \times R} \) in the total bundle) and the composition of the holonomies of \( C_R \) and of \( C_M \) is
\[ \text{Hol}_{t_0}^g(C_M \times R) \text{Hol}_{t_0}^a(C_M)^{-1} \text{Hol}_{t_0}^i(C_R) = P \gamma C_R e^{\int_{t_0}^{t_1} T(x,y) d^a_{\Theta_t} a^{\rho \
abla_{\Theta_t}} a^{\rho \
abla_{\Theta_t}}}, \]  

(53)

where \( x_0 = \chi_0^j h(y_0) \), \( C_M = \chi_0^j h(C_R) \) \( \in L_{x_0} M \), and \( C_M \times R = \{(\chi_0^j h(y), y) \in C_R \} \in L_{(x_0, y_0)} (M \times R) \). The second integral is along \( C_M \) (it is not ordered) and

\[ T(x,y) = P \gamma C_R e^{\int_{t_0}^{t_1} \tilde{\alpha}^{(a)}(x,y) \gamma C_R e^{\int_{t_0}^{t_1} \tilde{\alpha}^{(a)}(x,y)}, \]  

(54)

This theorem can be viewed as an equivalent of the non-abelian Stokes theorem (Ref. 11) in the composite bundle, and it is proven in Appendix A. The term appearing in the right hand side of Eq. (53) is gauge equivariant: if

\[ A_{\alpha}(x,y) = g(x,y)^{-1} A^a_{\alpha}(x,y) g(x,y) + g(x,y)^{-1} d_{M \times R} g(x,y), \]  

(55)

then

\[ P \gamma C_R e^{\int_{t_0}^{t_1} T(x,y) d^a_{\Theta_t} a^{\rho \
abla_{\Theta_t}} a^{\rho \
abla_{\Theta_t}}} \gamma C_R e^{\int_{t_0}^{t_1} T(x,y) d^a_{\Theta_t} a^{\rho \
abla_{\Theta_t}} a^{\rho \
abla_{\Theta_t}}} \gamma C_R e^{\int_{t_0}^{t_1} T(x,y) d^a_{\Theta_t} a^{\rho \
abla_{\Theta_t}} a^{\rho \
abla_{\Theta_t}}} \gamma C_R e^{\int_{t_0}^{t_1} T(x,y) d^a_{\Theta_t} a^{\rho \
abla_{\Theta_t}} a^{\rho \
abla_{\Theta_t}}} \]  

(56)

The composite holonomy is the composition of the component holonomies if and only if the intertwining curvature vanishes \( D^a_{\Theta_t} A_{Q_t}^{\alpha(a)} = d_{M \times R} A_{Q_t}^{\alpha(a)} = 0 \).

If we relax the second assumption by supposing that \( C_M \) crosses several charts \( U^a \), the works of Alvarez in Ref. 12 show that the correct definition of the holonomy of \( C_M \times R \) is

\[ \text{Hol}_{t_0}^i(C_M \times R) = P \gamma C_R e^{\int_{t_0}^{t_1} T(x,y) d^a_{\Theta_t} a^{\rho \
abla_{\Theta_t}} a^{\rho \
abla_{\Theta_t}}} \gamma C_R e^{\int_{t_0}^{t_1} T(x,y) d^a_{\Theta_t} a^{\rho \
abla_{\Theta_t}} a^{\rho \
abla_{\Theta_t}}} \gamma C_R e^{\int_{t_0}^{t_1} T(x,y) d^a_{\Theta_t} a^{\rho \
abla_{\Theta_t}} a^{\rho \
abla_{\Theta_t}}} \gamma C_R e^{\int_{t_0}^{t_1} T(x,y) d^a_{\Theta_t} a^{\rho \
abla_{\Theta_t}} a^{\rho \
abla_{\Theta_t}}} \]  

(57)

where \( U^a, U^b, \ldots, U^s \) are the charts crossed by \( C_M \), \( \chi_0^j h \) is an arbitrary point on \( U^a \cap U^b \cap C_M \), and \( y^{a \beta} \) is the point of \( C_R \), such that \( \chi_0^j h(y^{a \beta}) = \chi_0^j h(x^{a \beta}) \). The preceding expression is independent of the choice of the patches \( \{(a \beta)_{\alpha \beta}, \alpha \beta \} \). We can then apply Theorem 1 on each piece of \( C_M \times R \), i.e.,

\[ \text{Hol}_{t_0}^i(C_M \times R) = P \gamma C_R e^{\int_{t_0}^{t_1} T(x,y) d^a_{\Theta_t} a^{\rho \
abla_{\Theta_t}} a^{\rho \
abla_{\Theta_t}}} \gamma C_R e^{\int_{t_0}^{t_1} T(x,y) d^a_{\Theta_t} a^{\rho \
abla_{\Theta_t}} a^{\rho \
abla_{\Theta_t}}} \gamma C_R e^{\int_{t_0}^{t_1} T(x,y) d^a_{\Theta_t} a^{\rho \
abla_{\Theta_t}} a^{\rho \
abla_{\Theta_t}}} \gamma C_R e^{\int_{t_0}^{t_1} T(x,y) d^a_{\Theta_t} a^{\rho \
abla_{\Theta_t}} a^{\rho \
abla_{\Theta_t}}} \]  

(58)

The simple composition of the component holonomies does not appear because of the higher degree of intertwining due to the chart transitions.

Now we relax the first assumption by supposing that \( C_R \) crosses several charts \( V \). Let \( C_M^i = \{(\chi_0^j h(y), y) \in C_R \cap V \} \). \( C_M \) and \( C_M \times R \) are now two collections of disconected paths. Let \( y^{i j} \) be an arbitrary point on \( V^i \cap V^j \cap C_M \), \( x^{i j} = \chi_0^j h(y^{i j}) \), and \( x^{i j} = \chi_0^j h(y^{i j}) \) be the images of \( y^{i j} \) on the two disconnected paths \( C_M \) and \( C_M \). We note that \( \phi^{i j}(x^{i j}) = \chi_0^j h(y^{i j}) \). The direct generalization of the Alvarez formula,

\[ P \gamma C_M e^{\int_{(\chi_0^j h(y^{i j}), y^{i j})} T(x^{i j}, y^{i j}) \gamma C_M e^{\int_{(\chi_0^j h(y^{i j}), y^{i j})} T(x^{i j}, y^{i j}) \gamma C_M e^{\int_{(\chi_0^j h(y^{i j}), y^{i j})} T(x^{i j}, y^{i j}) \gamma C_M e^{\int_{(\chi_0^j h(y^{i j}), y^{i j})} T(x^{i j}, y^{i j})}}, \]  

(59)

is well defined. Indeed, it is independent of the arbitrary point \( y^{i j} \). Let \( \hat{y}^{i j} \) be another arbitrary point on \( V^i \cap V^j \cap C_R \). We have then

\[ P \gamma C_M e^{\int_{(\chi_0^j h(y^{i j}), y^{i j})} T(x^{i j}, y^{i j}) \gamma C_M e^{\int_{(\chi_0^j h(y^{i j}), y^{i j})} T(x^{i j}, y^{i j}) \gamma C_M e^{\int_{(\chi_0^j h(y^{i j}), y^{i j})} T(x^{i j}, y^{i j}) \gamma C_M e^{\int_{(\chi_0^j h(y^{i j}), y^{i j})} T(x^{i j}, y^{i j})}}, \]  

(60)

We have, moreover,
\[ P_{C_M \times R} e^{\phi_{(\theta)}(\bar{y}^j, y^i)} A_{ij} = P_{C_M \times R} e^{\phi_{(\theta)}(\bar{y}^j, y^i)} A_{ij} \]

(61)

\[ = P_{C_M \times R} e^{\phi_{(\theta)}(\bar{y}^j, y^i)} \bar{A}_{ij} . \]

(62)

Since \( \phi_{(\theta)} A_{+} = \bar{g}_{++}^{-1} \bar{A}_{+} A_{+} \bar{g}_{++} + \bar{g}_{++}^{-1} d_{M \times R} \bar{g}_{++}^{-1} \), we have

\[ P_{C_M \times R} e^{\phi_{(\theta)}(\bar{y}^j, y^i)} A_{ij} = \bar{g}_{++}^{-1} \bar{A}_{ij} \bar{g}_{++}^{-1} P_{C_M \times R} e^{\phi_{(\theta)}(\bar{y}^j, y^i)} \bar{A}_{ij} \bar{g}_{++}^{-1} \bar{A}_{ij} \bar{g}_{++}^{-1} \bar{g}_{++}^{-1} d_{M \times R} \bar{g}_{++}^{-1} \).

(63)

We see then that

\[ P_{C_M \times R} e^{\phi_{(\theta)}(\bar{y}^j, y^i)} A_{ij} = P_{C_M \times R} e^{\phi_{(\theta)}(\bar{y}^j, y^i)} \bar{A}_{ij} . \]

(64)

The formula is then well defined since it is independent of the arbitrary choice of points \{\( y^j \)\}. We can then define the composite holonomy by

\[
\text{Hol}_{A_{+}}(\{C_M \times R\}) = P_{C_M \times R} e^{\phi_{(\theta)}(\bar{y}^j, y^i)} \bar{A}_{ij} e^{\phi_{(\theta)}(\bar{y}^j, y^i)} P_{C_M \times R} e^{\phi_{(\theta)}(\bar{y}^j, y^i)} \bar{A}_{ij} e^{\phi_{(\theta)}(\bar{y}^j, y^i)} \]

\[ \times P_{C_M \times R} e^{\phi_{(\theta)}(\bar{y}^j, y^i)} \bar{A}_{ij} e^{\phi_{(\theta)}(\bar{y}^j, y^i)} P_{C_M \times R} e^{\phi_{(\theta)}(\bar{y}^j, y^i)} \bar{A}_{ij} e^{\phi_{(\theta)}(\bar{y}^j, y^i)} \ldots \]

\[ \times P_{C_M \times R} e^{\phi_{(\theta)}(\bar{y}^j, y^i)} \bar{A}_{ij} e^{\phi_{(\theta)}(\bar{y}^j, y^i)} P_{C_M \times R} e^{\phi_{(\theta)}(\bar{y}^j, y^i)} \bar{A}_{ij} e^{\phi_{(\theta)}(\bar{y}^j, y^i)} \]

(65)

where \( V^i, V^j, \ldots, V^N \) are the charts crossed by \( C_R \) (we have supposed that \( \forall i, C_M \subset U^i \)). If we relax both the two assumptions, then the composite holonomy formula is a mixing of formulas (58) and (65).

**IV. APPLICATIONS**

In this section we apply the formalism of the principal composite bundle to model two physical problems:

- the dynamics of a quantum system interacting with a classical environment and described by an active space and non-Abelian geometric phases,
- the transport of a classical Dirac spinor field coupled with the gravitational field associated with the curved space-time of the general relativity.

In this two situations we present the application of Theorem 1.

**A. Non-Abelian geometric phases of a quantum system interacting with a classical environment**

We consider a quantum system described by the Hilbert space \( \mathcal{H} \) and the free self-adjoint Hamiltonian \( H_0 \in \mathcal{L}(\mathcal{H}) \) [\( \mathcal{L}(\mathcal{H}) \)] denotes the space of linear operators of \( \mathcal{H} \)]. The quantum system interacts with an environment described by \( n \) classical parameters \( \tilde{R} \) via the self-adjoint interaction operator \( \tilde{H}_f(\tilde{R}) \in \mathcal{L}(\mathcal{H}) \) [we suppose that \( H_0 \) and the family \( \{H_f(\tilde{R})\}_{\tilde{R} \in \mathcal{R}} \) have a common domain in which each operator is restricted]. The total Hamiltonian \( H(\tilde{R}) = H_0 + H_f(\tilde{R}) \) describes the quantum system interacting with its environment. If we suppose that there exists \( m \) smooth constraints on the classical parameters \( \tilde{R} \): \( f_i(\tilde{R}) = 0 \) \( i = 1, \ldots, m \), \( f^i : \mathbb{R}^n \rightarrow \mathbb{R} \), then the admissible \( \tilde{R} \) form a smooth \((n-m)\)-dimensional submanifold \( M \) of \( \mathbb{R}^n \). These constraints can have for origin the fact that the parameters could be not physically independent or else they could be chosen by an experimentalist who controls the environment. We denote by \( (x^\mu)_{\mu = 1, \ldots, n-m} \) a coordinate system on \( M \) (and we write \( \tilde{R} = x \) if \( \tilde{R} \in M \)). Let \([0, T]\) be the fixed time interval of the evolution (0 can be the
date of the preparation of the system and $T$ can be the date of the experimental measurement). We consider only closed evolutions $[0,T] \ni t \mapsto \tilde{R}(t) \in M$, such that $\tilde{R}(0) = \tilde{R}(T) = x_0$ with $H_f(x_0) = 0$ ($x_0$ corresponds to the off interaction). Since $\tilde{R}(0) = \tilde{R}(T)$ for all evolutions, we can consider $t \in [0,T]$ as a coordinate on the circle $S^1$.

We suppose that there exist $N < \dim \mathcal{H}$ orthonormalized $x$-dependent vectors $(|A,x\rangle^a \in \mathcal{H})_{A=1,\ldots,N}$ (depending on a system of local charts $\{U^a\}_\alpha$ on $M$), such that

$$\forall t \in [0,T], \quad U(t,0)P(x_0) = P(x(t))U(t,0) \quad \text{for all evolution } t \mapsto x(t),$$

(66)

where $P(x) = \sum_{N} |A,x\rangle^a \langle A,x|$ is the rank $N$ orthogonal projector on the space spanned by $(|x,A\rangle^a \in \mathcal{H})_{A=1,\ldots,N}$ (the active space), and where $U(t,0)$ is the evolution operator, i.e.,

$$\frac{dU(t,0)}{dt} + H(x(t))U(t,0), \quad U(t,0) = T e^{-i h \int_0^t H(x(t'))dt'},$$

(67)

$T$ is the time ordering operator. $\forall x \in U^a \cap U^b$, $g^{ab}(x)_{AB} = \delta^a_B A_B^x x^a$ is an element of a basis change matrix within the active space. Such a set of vectors is, for example, given by an adiabatic theorem (see, for example, Ref. 13) [in that case each $|A,x\rangle$ is an eigenvector of $H(x) = H_0 + H_f(x)$]. We suppose that the initial wave function of the quantum system is $\psi(0) = |A,x_0\rangle^a$; under the assumption, Eq. (66), we can prove (see Refs. 5 and 14) that

$$\psi(t) = \sum_{B=1}^N \left[ T e^{-i h \int_0^t E^a(x(t))dt - i \int_0^t A^a_{\mu}(x(t))(dx^\mu(t)/dt)dt} \right]_{BA} |B,x_0\rangle^a,$$

(68)

with

$$E^a(x)_{AB} = \delta^a_B A_B^x x^a, \quad A^a_{\mu}(x) = \frac{\partial}{\partial x^\mu} |B,x\rangle^a.$$  

(69)

We have, moreover, supposed that $\mathcal{C}_M$ [the path parametrized by $t \mapsto x(t)$] is totally included in $U^a$.

The quantum dynamics is then described by the composite bundle $P_x(M \times S^1, U(N)) \to M \times S^1 \to S^1$ [where $U(N)$ is the Lie group of the order $N$ unitary matrices]. The structure bundle $P(M, U(N)) \to M$ is defined by the transition function $g^{ab} \in \Omega^1(U^a \cap U^b, U(M))$. Since the base bundle $M \times S^1 \to S^1$ is trivial, the composite transition functions are simply $g^{ab}(x,t) = g_{b}(x)$ for all opens $V^a$ and $V^b$ and the torsion functions are reduced to the identity map. The manifold $P_x$ is then $P \times S^1$. The transversal bundles are then the trivial bundles $Q_{-}^a \times \phi^a_{P_x}(G) \to S^1$ ($\phi^a_{P_x}(G) = \pi^{-1}_P(x)$). The composite bundle is endowed with the composite connection defined by the gauge potential

$$\tilde{A}^a_p = ih^{-1}E^a(x)dt + A^a_{\mu}(x)(dx^\mu / dt) \in \Omega^1(U^a \times S^1, u(N)),$$

(70)

where $A_p \in \Omega^1(U^a, u(N))$ is the gauge potential of $P(M, U(N))$ and where $\tilde{A}^a_Q(t) = ih^{-1}E^a(x)dt \in \Omega^1(S^1, u(N))$ is the gauge potential of $Q_{+}^a(S^1, U(N))$ [$u(N)$ is the Lie algebra of the order $N$ anti-self-adjoint matrices]. We note that the gauge of decomposition is conserved while the basis changes of the active space are assumed to be time-independent. The non-Abelian phase appearing in the expression of the wave function, Eq. (68), is the holonomy of the section $h \in \Gamma(S^1, M \times S^1)$ defined by $h(t) = (x(t), t)$,

$$T e^{i h^{-1} \int_0^t E^a(x(t))dt - i \int_0^t A^a_{\mu}(x(t))(dx^\mu(t)/dt)dt} = \text{Hol}_h(\mathcal{C}_M \times S^1).$$

(71)

The study of quantum dynamics by the non-Abelian geometric phase formulation is well established when $\forall x, x' \in M$, $\forall \mu$, $[E(x), A^a_{\mu}(x')] = 0$ [a such assumption is satisfied when all vectors $|A, x\rangle$ are eigenvectors associated with a single $N$ degenerate eigenvalue $e(x)$ of $H(x)$]. In that case we have
The separation of the dynamical phase and of the geometric phase permits the use of the properties of each one to understand the dynamics. In the case of an $N$-fold degenerate eigenvalue, $T e^{iE_i(\alpha) \delta t} = e^{iE_i(\alpha) \delta t} i d_N$ is just an Abelian phase ($i d_N$ is the order $N$ identity matrix), the properties concerning the state transitions are then encoded only by the geometry of $P(M, G)$. This fact is used to develop quantum control methods (see Ref. 15). However, if the generators do not commute, $[E(x), A_i(x)] \neq 0$, the usual formulas do not separate the geometric and the dynamical phase. By applying Theorem 1, we find another separation if

$$\frac{\partial}{\partial x^\mu} E^\alpha(x) + [A^\mu_\alpha(x), E^\alpha(x)] = 0 \quad \forall \ x \in U^\alpha, \ \forall \mu.$$  

(73)

In other words, in place of assuming the nonlocal commutation of the dynamical and the geometric generators, we assume that the dynamical generator is a local geometric coinvariant (by local we mean that the condition depends only on one point, and a geometric coinvariant is the analog of a dynamical invariant where the gauge potential takes the place of the Hamiltonian). We have then

$$\text{Hol}_{\lambda_{\mu}}^\alpha(C_{M \times S^1}) = e^{iE^\alpha(x) T \mu \alpha} e^{iA^\alpha_M}.$$  

(74)

However, the intertwining curvature vanishing condition can be very drastic. We can relax it, by assuming the following condition:

$$\frac{\partial}{\partial x^\mu} E^\alpha(x) + [A^\mu_\alpha(x), E^\alpha(x)] = \lambda_\mu(x) i d_N \quad \forall \ x, \ \forall \mu,$$  

(75)

where $\lambda_\mu$ is a real smooth function. In that case, we have

$$\text{Hol}_{\lambda_{\mu}}^\alpha(C_{M \times S^1}) = e^{iE^\alpha(x) T \mu \alpha} e^{iA^\alpha_M}.$$  

(76)

The intertwining term $e^{iE^\alpha(x) T \mu \alpha} e^{iA^\alpha_M} i d_N$ is just an Abelian phase which does not participate in the transitions between the states $\{[A, x]^{\alpha}\}^A$.

By using the Leibniz rule, we have a non-Abelian generalization of the Hellmann–Feynman theorem,

$$\frac{\partial}{\partial x^\mu} C^\alpha_{AB} = -[A^\mu_\alpha, E^\alpha]_{AB} + \lambda_\mu(x) [\frac{\partial H}{\partial x^\mu}, [B, x]]^\alpha.$$  

(77)

Assumption (75) is then realized if $\{[A, x]^{\alpha}\}^A$ is a set of eigenvectors of all operators $\frac{\partial H}{\partial x^\mu}$ associated with single $N$ degenerate eigenvalues,

$$\frac{\partial H}{\partial x^\mu} [A, x]^{\alpha} = \lambda_\mu(x) [A, x]^{\alpha}.$$  

(78)

Remark: Even if $Q^\alpha \rightarrow S^1$ is trivial, the holonomy in this bundle does not vanish since the base manifold $S^1$ is topologically untrivial.

**B. Dirac spinor field transport in a curved space-time**

In this section we suppose that $\hbar = c = \epsilon = 1$.

Let $M$ be the space-time manifold which is endowed with a metric $g_{\mu\nu}(x)$ and with a linear connection (the Christoffel symbols) $\Gamma^\mu_{\nu\lambda}(x)$ ($x^\mu_{\mu=0,\ldots,3}$ is a space-time coordinates system). To describe spinor fields in the curved space-time, we need to consider two other entities. The first one is a Lorentz connection (the so-called spin-connection) $\omega = \omega^A_{\mu}(x) M_{AB} dx^B \in \Omega^1(M, \mathfrak{h})$, where
\[ \{M_{AB}\}_{A,B=0,\ldots,3} \] are the generators of the Lie algebra \( \mathfrak{h} \) of the Lorentz group \( H=SO(3,1) \). The second one is a set of vectors forming an orthogonal tangent basis and called tetrads or vierbeins, \( \{e^A_\mu(x)\}_{A,\mu=0,\ldots,3} \). A vierbein is transformed under a local Lorentz transformation \( h(x) \in H \) as \( e^A_\mu(x) = h(x)e^A_B(x) \), and the transversal bundle \( Q_{\mu}(M,H) \to M \) by the spinorial representation of the linear connection associated with the following gauge potential:

\[ A_Q(h) = e^A_\mu dx^\mu M_{AB} \in \Omega^1(G/H,\mathfrak{h}), \]

and the transversal bundle \( Q_{\nu}(M,H) \to M \) by the spinorial representation of the linear connection associated with the following gauge potential:

\[ A_Q(h) = \frac{1}{2} \left[ \gamma_A, \gamma_B \right] \]
\[ \tilde{A}_{QeH}(x) = \epsilon^A_{\mu} \Gamma^{B\nu}_{\rho\delta}(x) A^B x^{\nu} M_{AB} dx^\rho \in \Omega^1(M, h). \]  
(We omit the chart indices, which play no role in this discussion.) Let \( \sigma=(x \rightarrow e(x)H) \in \Gamma(M, S) \) be a local section of \( S(M, G/H) \rightarrow M \). We have

\[ \sigma^* \tilde{A}_a(x) = (e^A_{\mu}(x) \partial_{\mu} e^{B\nu}(x) + e^A_{\mu}(x) \Gamma^{B\nu}_{\rho\delta}(x) A^B x^{\nu} M_{AB}) dx^\rho \]

\( = \omega. \)  
(88)

The Lorentz gauge potential is then the composition of the Cartan gauge potential and of the linear potential. \( \mathcal{D}(\omega) \) is the gauge potential associated with the spinorial covariant derivative \( \nabla^\mu \), Eq. (83). In contrast to the approach of Tresguerres' in which the vierbeins appear as a translational gauge potential of a Poincaré gauge theory of the gravity, in this approach the vierbeins are not fixed by the connection, whereas their equivalence classes form the auxiliary space-time \( G/H \) on which the gauge theory is built.

Holonomies associated with the Lorentz connection play an important role in the quantization of the gravity (see Refs. 17 and 18). Let two separate particles at the space-time point \( x_0 \) with the same spinor state \( \tilde{\psi}_0 \). The first particle is transported along the worldline \( C_a \) from \( x_0 \) to \( x_1 \) and the second particle is transported along another worldline \( C_b \) from \( x_0 \) to \( x_1 \). This situation means that the particles are described by the semiclassical spinor fields as \( \tilde{\psi}_a(x) = \int_{x_0}^{x_1} \tilde{\psi}_a(s) \delta(x - x_a(s)) dx, \) where \( s \rightarrow x_a(s) \) is the parametrization of the worldline of the particle \( a \) and \( \tilde{\psi}_a(s) \) is the spinor state at the proper time \( s \) along the worldline with \( \tilde{\psi}_a(s_0) = \tilde{\psi}_0(x_a(s_0) = x_0) \). After the transportations \( x_a(s_1a) = x_b(s_{1b}) \), the spinor states of the two particles are related by

\[ \tilde{\psi}_b(s_{1b}) = \mathcal{D}(\text{Hol}_{\tilde{A}_a}(C_{M \times G/H})) \tilde{\psi}_b(s_{1b}), \]  
(89)

where \( C_{M} = C_a \circ C_b^{-1} \in \mathcal{L}(M) \) and \( C_{M \times G/H} = \{(x(s), e(x(s))H), s \in [0, s_{1a} + s_{2b} - 2s_0]\} \in \mathcal{L}(x_0, e(x_0)H)(M \times G/H), s \) being the curvilinear coordinate along \( C_{M} \) and \( x \rightarrow e(x)H \) being a local section of \( S(M, G/H) \rightarrow M \) over \( C_{M} \) [associated with the vierbeins \( x \rightarrow e^{\lambda}_{\mu}(x) \)]. By applying Theorem 1, we have

\[ \Gamma_{\epsilon M}^e \epsilon^{\rho \mu} = \text{Hol}_{\tilde{A}_a}(C_{M \times G/H}) \]  
(90)

\[ = \Gamma_{\epsilon M}^e \epsilon^{\rho \mu} = \mathcal{D}(\text{Hol}_{\tilde{A}_a}(C_{M \times G/H})) \text{Hol}_{\tilde{A}_a}(C_{M \times G/H}), \]  
(91)

where \( \text{Hol}_{\tilde{A}_a}(C_{M \times G/H}) \) is the holonomy associated with the representation of the linear connection on the spinor states at the base point \( x_1 \) and where \( \text{Hol}_{\tilde{A}_a}(C_{G/H}) \) is the holonomy associated with the Cartan connection. The intertwining curvature is (see Appendix B)

\[ D_{G,H} \tilde{A}_{QeH} = (\epsilon^B_{\nu} e^{A \lambda} x^{\lambda} - e^{B \nu} \epsilon^{A \lambda} x^{\lambda}) \wedge \Gamma_{\rho \mu}^e M_{AB}. \]  

We can note an interesting analogy between the non-Abelian geometric phases treated in the previous application: the Cartan connection \( A_{QeH} \) plays the role of the geometric phase generator, \( \tilde{A}_{QeH} \) plays the role of a dynamical phase generator, the vierbeins play the role of the active space basis vectors, and the Christoffel symbol \( \Gamma_{\rho \mu}^e \) takes the place of the Hamiltonian.

The author thanks Professor John P. Killingbeck for his help.
APPENDIX A: DEMONSTRATION OF THEOREM 1

Since all relevant quantities are defined on the single local chart $U^\alpha \times V^i$, we omit the indices $\alpha$ and $i$,

\[ P_{C_M \times R} e^{\delta \tilde{A}_\lambda} = P_{C_R} e^{\delta \tilde{A}_\lambda} e^{f^{(A)}_{0} Q_0} \tilde{A}_\lambda e^{-f^{(A)}_{0} Q_0}. \]  

(A1)

We split this expression by using the intermediate representation theorem (see Ref. 19),

\[ P_{C_M \times R} e^{\delta \tilde{A}_\lambda} = P_{C_R} e^{\delta \tilde{A}_\lambda} e^{f^{(A)}_{0} Q_0} \tilde{A}_\lambda e^{-f^{(A)}_{0} Q_0} - A_{Q_0} = \int_{\lambda_0}^\lambda d\lambda \left( P_{C_R} e^{\delta \tilde{A}_\lambda} e^{f^{(A)}_{0} Q_0} \tilde{A}_\lambda e^{-f^{(A)}_{0} Q_0} \right). \]  

(A2)

Moreover, we have

\[ P_{C_M} e^{f^{(A)}_{0} Q_0} \tilde{A}_\lambda e^{-f^{(A)}_{0} Q_0} - A_{Q_0} = \int_{\lambda_0}^\lambda d\lambda \left( P_{C_M} e^{f^{(A)}_{0} Q_0} \tilde{A}_\lambda e^{-f^{(A)}_{0} Q_0} \right). \]  

(A3)

By using the Leibniz rule with $d_{\lambda}$ in the right hand side of the preceding equation and the fact that $d_{\lambda} P_{C_M} e^{f^{(A)}_{0} Q_0} e^{-f^{(A)}_{0} Q_0} = -A_{Q_0} P_{C_M} e^{f^{(A)}_{0} Q_0} e^{-f^{(A)}_{0} Q_0}$, we find that

\[ P_{C_M} e^{f^{(A)}_{0} Q_0} \tilde{A}_\lambda e^{-f^{(A)}_{0} Q_0} - A_{Q_0} = \int_{\lambda_0}^\lambda P_{C_M} e^{f^{(A)}_{0} Q_0} (d_{\lambda} \tilde{A}_\lambda + [A_{\lambda}, \tilde{A}_\lambda]) P_{C_M} e^{-f^{(A)}_{0} Q_0} \]  

(A4)

\[ = \int_{\lambda_0}^\lambda P_{C_M} e^{f^{(A)}_{0} Q_0} D_\lambda \tilde{A}_\lambda e^{-f^{(A)}_{0} Q_0}. \]  

(A5)

We then have

\[ P_{C_M \times R} e^{\delta \tilde{A}_\lambda} = P_{C_R} e^{\delta \tilde{A}_\lambda} e^{f^{(A)}_{0} Q_0} D_\lambda \tilde{A}_\lambda e^{-f^{(A)}_{0} Q_0} \]  

(A6)

Finally, by using again the intermediate representation theorem, we have

\[ P_{C_M \times R} e^{\delta \tilde{A}_\lambda} = P_{C_M} e^{f^{(A)}_{0} Q_0} D_\lambda \tilde{A}_\lambda e^{-f^{(A)}_{0} Q_0} + \frac{e^{f^{(A)}_{0} Q_0}}{\beta^{(A)}_{0}} e^{f^{(A)}_{0} Q_0} \tilde{A}_\lambda e^{-f^{(A)}_{0} Q_0} \]  

(A7)

APPENDIX B: INTERTWINING CURVATURE OF GRAVITY

\[ D_G \tilde{A}_{Q_H} = d e^{A}_{\rho} \wedge \Gamma^{\nu}_{\rho\sigma} d x^\nu e^{B\nu}_{\rho} M_{AB} + e^{A}_{\nu} \tau^{\mu}_{\nu\rho} d x^\rho M_{AB} + e^{A}_{\nu} \tau^{\mu}_{\nu\rho} d x^\rho \]  

(B1)

The commutation relations of the Lorentz algebra $\mathfrak{h}$ being

\[ [M_{AB}, M_{CD}] = -\eta_{BD} M_{AC} + \eta_{BC} M_{AD} + \eta_{AD} M_{BC} - \eta_{AC} M_{BD}. \]  

(B2)

we have
After the exchange of some double indices, we find

\[ D_G A_{QH} = \frac{\text{de}^A e^B - e^A_{\mu} e^B_{\mu} \Gamma^\nu_{\rho \lambda} \text{de}^\nu_{\rho} M_{AB} + e^A_{\mu} e^B_{\mu} \Gamma^\rho_{\lambda \mu} \text{de}^\rho \lambda M_{AB} - e^A_{\mu} e^B_{\mu} e^C \Gamma^\nu_{\rho \lambda} \text{de}^\nu_{\rho} M_{ABC} + e^A_{\mu} e^B_{\mu} e^C \Gamma^\rho_{\lambda \mu} \text{de}^\rho \lambda M_{AB}}{de^A e^B e^C} . \]

(B3)

Moreover, we have

\[ e^A_{\mu} e^B_{\mu} \Gamma^\rho_{\lambda \mu} \text{de}^\rho \lambda M_{AB} = \frac{\text{de}^A e^B}{\text{de}^C} \left( e^A_{\mu} e^B_{\mu} \Gamma^\rho_{\lambda \mu} \text{de}^\rho \lambda M_{AB} \right) . \]

(B4)

\[ e^A_{\mu} e^B_{\mu} e^C \Gamma^\rho_{\lambda \mu} \text{de}^\rho \lambda M_{ABC} = \frac{\text{de}^A e^B}{\text{de}^C} \left( e^A_{\mu} e^B_{\mu} e^C \Gamma^\rho_{\lambda \mu} \text{de}^\rho \lambda M_{ABC} \right) . \]

(B5)

Since \( e^A_{\mu} e^B_{\mu} \Gamma^\rho_{\lambda \mu} \text{de}^\rho \lambda M_{AB} = \frac{\text{de}^A e^B}{\text{de}^C} \left( e^A_{\mu} e^B_{\mu} \Gamma^\rho_{\lambda \mu} \text{de}^\rho \lambda M_{AB} \right) \), we have

\[ e^A_{\mu} e^B_{\mu} \Gamma^\rho_{\lambda \mu} \text{de}^\rho \lambda M_{AB} = \frac{\text{de}^A e^B}{\text{de}^C} \left( e^A_{\mu} e^B_{\mu} \Gamma^\rho_{\lambda \mu} \text{de}^\rho \lambda M_{AB} \right) . \]

(B6)

Since \( e^A_{\mu} e^B_{\mu} \Gamma^\rho_{\lambda \mu} \text{de}^\rho \lambda M_{AB} = \frac{\text{de}^A e^B}{\text{de}^C} \left( e^A_{\mu} e^B_{\mu} \Gamma^\rho_{\lambda \mu} \text{de}^\rho \lambda M_{AB} \right) \), we have

\[ e^A_{\mu} e^B_{\mu} \Gamma^\rho_{\lambda \mu} \text{de}^\rho \lambda M_{AB} = \frac{\text{de}^A e^B}{\text{de}^C} \left( e^A_{\mu} e^B_{\mu} \Gamma^\rho_{\lambda \mu} \text{de}^\rho \lambda M_{AB} \right) . \]

(B7)

We then have

\[ D_G A_{QH} = \left( e^A_{\mu} e^B_{\mu} \Gamma^\rho_{\lambda \mu} \text{de}^\rho \lambda M_{AB} \right) . \]

(B8)

Moreover, we have

\[ e^A_{\mu} e^B_{\mu} \Gamma^\rho_{\lambda \mu} \text{de}^\rho \lambda M_{AB} = \frac{\text{de}^A e^B}{\text{de}^C} \left( e^A_{\mu} e^B_{\mu} \Gamma^\rho_{\lambda \mu} \text{de}^\rho \lambda M_{AB} \right) . \]

(B9)

because \( M_{BA} = -M_{AB} \). Finally, we have

\[ D_G A_{QH} = \left( e^A_{\mu} e^B_{\mu} \Gamma^\rho_{\lambda \mu} \text{de}^\rho \lambda M_{AB} \right) . \]

(B10)

\[ D_G A_{QH} = \left( \text{e}^A_{\mu} e^B_{\mu} \Gamma^\rho_{\lambda \mu} \text{de}^\rho \lambda M_{AB} \right) . \]

(B11)
